Replying, on July 30th, to Mr. Hales, Mr. SHAKESPEARE said that only one case of diphtheria was notified in the Campden Rural District during the last four months. In his annual report the medical officer of health reported that twenty-one cases occurred in 1933, most of them at the Chipping Campden Grammar School. The Minister of Health had no information that the outbreak was attributed to infection from bathing, and he was not aware that the causal organism of diphtheria had ever been found in water. The Public Health Act, 1875, gave the local authority, or any of its officers, a right of entry to any premises for the purpose of ascertaining whether any nuisance existed, and the Minister did not think it would be good policy that detailed inspection of swimming pools should be carried out by officers of the central authority. The Minister intended to call attention to the powers of local authorities in his next annual report, which would shortly be issued.

Medical Education on Industrial Diseases

On the motion for the adjournment for the summer recess, on July 31st, a debate took place on factory conditions, initiated by Mr. Rhys Davies. Sir F. FREMANTLE said there was no question but that an improvement in the health of persons engaged in factories and workshops depended not only on the Inspectorate, but much more on the individual work of certifying surgeons, and still more on the relations, which were not yet properly established, between the factories and workshops and the schools. The child entering at an early stage on an industrial career in factory or workshop should be properly directed and guided. There should be co-operation between the health side of the Home Office and the Board of Education in this matter. It was clear that a large number of people were careless and disregarded certain risks, and that there was necessity for educating individual workers, especially the younger ones, in protecting themselves against accident. Attention should be directed to a necessary change in medical education. Ordinary medical education was conducted in the hospitals by men engaged in the treatment of individual disease. Therefore, very little provision was made to teach the ordinary budding doctor in regard to prevention, and especially in regard to methods of dealing with industrial disease and conditions in factories. Captain CROOKSHANK suggested that during the recess members might get in touch with employers and workpeople, and bring remarks on the question of accidents contained in the report of the Chief Inspector of Factories to their notice. These things were largely a matter of education. The point which struck one in the report was the almost incredible number of avoidable accidents. The increase of accidents, however, must not be taken as any indication of failure on the part of a hard-working department of the Home Office.

Liquid Eggs Importation.—Sir HILTON YOUNG told Colonel Ackland-Troyte, on July 19th, that he had no information to show that the United States of America or any other countries prohibited the importation of liquid eggs on grounds of health. Liquid eggs imported into this country and intended for food must be free from preservatives and fit for human consumption, and, subject to these conditions, he was unaware of any reason for prohibiting their importation on grounds of health. Precautions were taken to ensure that liquid eggs were fit for human consumption.

Encephalitis following Vaccination.—Sir HILTON YOUNG told Mr. Groves, on July 26th, that his attention had been called to the death of an 18-year-old boy from encephalitis, resulting from vaccination performed as a condition of employment with

the Gas Light and Coke Company. The opinion had already been expressed, in circulars issued by his Department, that it was not generally expedient to press for the vaccination of children of school age, or of adolescents who had not previously been vaccinated, unless they had been in personal contact with a case of small-pox, or directly exposed to small-pox infection.

Vaccination and Admission to Day Nurseries.—In reply to Mr. Groves, on July 26th, Sir HILTON YOUNG stated he was unaware that certain day nurseries refused to admit unvaccinated infants, some of whom had been legally exempted from vaccination by the statutory declaration of their parents. This was a matter within the discretion of the authorities of the day nursery, and he could not undertake to intervene.

Harmful Effects of Exhaust Fumes.—Mr. HORE-BELISHA told Mr. Albery, on July 30th, that the question of the harmful effects suffered in crowded thoroughfares as a result of the exhaust fumes of motor vehicles came under the consideration of a Home Office Departmental Committee a year ago. Its report did not suggest that there was any such evidence of injury being caused by exhaust fumes to the health of drivers and conductors or of persons using the highway as would justify legislative action. The examiners appointed under the Road Traffic Act, 1930, and the Road and Rail Traffic Act, 1933, however, were required to look for defects in exhaust pipes in the public service vehicles and goods vehicles which they examined.

L.C.C. and Treatment for Tuberculosis.—Sir F. FREMANTLE, on July 30th, asked the Minister of Health if he had considered the representations from the Standing Joint Committee of the metropolitan borough councils in reference to the proposals of the London County Council to provide institutional treatment for all tuberculous persons at the expense of the ratepayers, without regard to the circumstances of their patients, who had hitherto been assessed for contributions according to their means. Mr. SHAKESPEARE said that the Minister of Health did not find that he had received any such representations as were mentioned in the question.

Military and Civil Hospitals.—Major TRYON, on July 30th, informed Sir Wilfrid Sugden that the policy of the Ministry of Pensions was to make use of civil hospitals so far as possible consistently with the interests of the Ministry's patients, but there were certain types of war disability, as, for example, nervous and mental disorder, epilepsy, paraplegia, and certain types of surgical case, for which either ordinary civil institutions did not provide or which could be more suitably dealt with in specialized Ministry institutions. No change was contemplated in this policy, which would continue to be pursued so long as the interests of the patients demanded it. The number of cases (not including pensioners certified as of unsound mind in public mental hospitals) admitted as in-patients to military hospitals, including Queen Mary's Hospital, Roehampton, in 1931 was 7,501; in 1932, 6,264; and in 1933, 5,790. The number of similar cases admitted to voluntary hospitals and general civil hospitals in 1931 was 3,478; in 1932, 2,541; and in 1933, 1,966.

Medical Inspection in Board of Control Institutions.—On July 31st Dr. O'DONOVAN asked the Minister of Health if his attention had been drawn to remarks by the Recorder of the City of London concerning a woman detained at Epsom under Subsection (1) of Section 11 of the Mental Deficiency Act. Sir HILTON YOUNG said that these remarks appeared to have been based upon inadequate information. Apart from the periodical statutory review to which the Recorder referred, mental defectives in institutions were under the constant observation of the medical staff. Suitable cases were frequently given leave of absence to test their fitness for discharge, and the Board of Control could discharge any patient at any time. The question whether special inquiries should be instituted into the need of amendment of the Act with regard to the frequency of medical inspections did not therefore arise.

Compensation for Silicosis.—On the motion for the adjournment of the House of Commons, on July 30th, Mr. D. GRENFELL raised the question of compensation for silicosis. Captain CROOKSHANK said that the Home Secretary had now completed his review of the proposal submitted to him for the amendment of the silicosis compensation scheme for coal mines. The main fact which emerged was that he recognized that limitation of the scheme to particular underground pro-

MEDICAL NEWS

Aug. 4, 1934]

cesses gave rise to serious difficulties. He proposed, therefore, to extend the scheme so as to bring underground employment in coal mines generally within its scope.

Rural Water Supplies.—Sir HILTON YOUNG told Lord Scone, on July 26th, that the total estimated capital cost of schemes submitted for the £1,000,000 grant for improving rural water supplies was £2,040,000.

Food Poisoning in Lincolnshire.—Mr. SHAKESPEARE stated, on July 24th, that the Minister of Health has received reports from the district and county medical officers of health that about thirty persons in the Welton rural district of Lincolnshire have been affected by food poisoning, but that all have recovered. The cause of the outbreak has not been established, but some pickled meat is suspected.

Medical News

The Royal College of Physicians of London will be closed for cleaning on Saturday, August 4th, and will reopen on Monday, September 17th.

The next lecture-demonstration arranged by the Fellowship of Medicine and Post-Graduate Medical Association (1, Wimpole Street, W.) will be given at 11, Chandos Street, W., on August 14th, at 2.30 p.m., on hysteria; no lecture on August 7th. On August 11th, at 3 p.m., a demonstration on chest cases. A short course on fractures at the National Temperance Hospital, there will be a demonstration on chest cases. A short course on fractures will be given at St. George-in-the-East Hospital every afternoon from August 13th to 17th, at 2.30 p.m. The panel of teachers offers daily instruction in various branches of medicine and surgery.

The ninth Italian Congress of Hygiene will be held at Bari from September 20th to October 4th, under the presidency of Dr. Alberto Botti.

A conference on health education and propaganda, to which members of Cheshire local authorities, other statutory bodies, and voluntary organizations were invited, was held at Chester on July 18th. Mr. George Wright, president of the National Association of Insurance Committees and chairman of the Cheshire Insurance Committee, occupied the chair. A provisional joint committee, of which Mr. Wright is chairman, has been formed, and a draft scheme drawn up for the constitution of a Cheshire Joint Committee for Health Education and Propaganda. The object of the scheme generally is to give effect to the powers and duties of the Insurance Committee and local authorities under the Public Health Act, 1925. Dr. Ian Mackay, county medical officer of health, spoke on "Public Health—Historical, Present Services in Cheshire, and Possible Developments," and briefly outlined the development of public health work. The publicity director of the health services, Mr. F. F. Potter, director of education for Cheshire, discussed education in relation to health, hygiene, and well-being. Dr. J. W. Lobban (Chester) said his authority felt that health propaganda should be carried on to a great extent under the medical officer of health. The city council would be favourably disposed towards the scheme provided certain small matters could be adjusted.

The London County Council has issued an official statement on the dietaries of resident officers in hospitals and institutions. It appears from this that publicity has been given to a resolution passed at a "mass meeting" of officers of the Council's hospitals and institutions, held under the auspices of the National Union of County Officers at the Memorial Hall, May 16th. The resolution protested emphatically "against the system of rationing entered upon by resident officers," and the grounds upon which the protest was made included the statement "that generally the quality of the food supplied appears to be of the lowest possible standard." The resolution laying bare a communication to the L.C.C. by the National Union of County Officers, representatives of the union were invited to visit the Council's stores from which food

is supplied to the various hospitals and institutions, to inspect the supplies, and to see the general system and method in operation. This invitation was accepted, and the general secretary (Mr. G. Vincent Evans) and Mrs. B. M. Drapper visited the Council's stores at Peckham Rye on July 9th, inspected the whole of the premises and goods therein, and made a report. As the result, a communication, dated July 17th, was sent to the Council by the union, enclosing a copy of the report and stating that the union desired to withdraw completely from its submissions to the Council any question as to the quality of food as purchased by, and issued from, the supplies department, and expressing regret that any such reference was made.

The new Kent and Sussex Hospital at Tunbridge Wells was opened on July 25th by the Marchioness Camden, wife of the president. Built at a cost of £180,000, it replaces the amalgamated Tunbridge Wells and Counties General Hospital, which was established in 1828, and the Tunbridge Wells Eye and Ear Hospital, founded in 1878.

At the Manchester Assizes on July 20th Dr. John Tryweryn Lloyd, formerly of Liverpool, was sentenced by Mr. Justice Atkinson to twelve months' imprisonment in the second division on a charge of having broken recognizances entered into at the Liverpool Assizes last April when he had been found guilty of libelling and assaulting Mr. R. M. Williams, a local relieving officer. On that occasion Mr. Justice du Parc bound Dr. Lloyd over indefinitely. It was stated on July 20th that since then he had again libelled and assaulted Williams. Mr. O. G. Morris, who prosecuted, said that the relieving officer caused Dr. Lloyd's removal to hospital on suspicion of being of unsound mind.

The issue of the *Deutsche medizinische Wochenschrift* for July 20th is devoted to the proceedings of the fourth international radiological congress recently held in Zurich.

Mr. Henry Kimpton announces for early publication a new and revised edition of Professor William Boyd's *Textbook of Pathology*.

TRAFFIC IN WOMEN AND CHILDREN

A conference on "White Slave Traffic in the East" was held on July 25th at the London School of Hygiene and Tropical Medicine under the auspices of the joint standing committee of the British Social Hygiene Council and the Conference of British Missionary Societies. The Earl of Lytton presided at one session and Sir Cecil Clementi, late Governor of the Straits Settlements, at the other. The objects of this preliminary conference were to consider means for making effective the conference proposed to be held by the League of Nations (probably in Singapore) by increasing interest in the subject among non-official organizations in the East, so that co-operation between Governments and non-official organizations in combating the traffic in women might be made easier. Support for these objects was given from the Chinese and Japanese Legations, the Dutch East Indies, the League of Nations, and by the Bishop of Singapore, prominent members of Protestant and Catholic missions in the East, and the Salvation Army. The Colonial, Home, and War Office Departments of the Government were also represented. Notice was taken of the general movement of the tolerated-brothel system in Europe, for the elimination of this system in preventing disease and in assisting in the maintenance of the health of the community. Abolition of regulation and toleration and the setting up of free and efficient V.D. treatment centres, available for the whole community, were now believed to be the line of progress on the medical and health side, so that there is no longer any serious conflict between the moral and the medical outlook on the matter. A number of resolutions were carried strongly supporting further action by the League of Nations and by the various Eastern Governments, with a view to securing inter-governmental action, which at present was the main hindrance to the elimination of the traffic in women and children.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to The EDITOR, British Medical Journal, B.M.A. House, Tavistock Square, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication. Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111 (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are:
EDITOR OF THE BRITISH MEDICAL JOURNAL, Antiology
Westcent, London.
FINANCIAL SECRETARY AND BUSINESS MANAGER
(Advertisements, etc.), Articulate Westcent, London.
MEDICAL SECRETARY, Mediscra Westcent, London.

The address of the Irish Office of the British Medical Association is 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumshough Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh).

QUERIES AND ANSWERS

Excessive Weight in Childhood

"A B C" writes: A girl, 11 years old, weighs 11 st., and is 4 ft. 11 in. in height. Do cases like this tend to lose excessive weight at puberty? She is active in mind and body. I should be glad of any suggestions for treatment from your readers.

Nail-biting

"M.B.Ed." asks for suggestions in the treatment of nail-biting in an intelligent girl of 11, the daughter of highly educated and sensible parents. The girl is otherwise quite normal, and is apparently fit in every way, but is a little highly strung temperamentally.

Over-smoking

"F. C. R." (Sussex) would be glad to know of any way of stopping excessive cigarette smoking in a man of 34. The man has been a heavy smoker all his life, and has repeatedly tried to cut it down both for reasons of economy as well as for the symptoms produced.

Insect Bite Causing Gangrene of Finger

Dr. EDWARD C. B. IBOTSON (Jersey) sends the following additional note (see *Journal*, June 23rd, p. 1152): Dry gangrene on the back of the terminal phalanx spread down to the bone, and I had to amputate the phalanx on July 17th. Whatever the insect was, the patient states it to have been very small and hard to remove, but that the bite caused much pain. He applied tincture of iodine only. The bite was on June 10th. A groove of dry, black gangrene was present when he came first on June 13th.

Book Wanted and Found

Within a few hours of the publication of our last issue, with its request from "W. G. R." for Sutherland's *Dispensing Made Easy*, we received by hand a copy from a reader in London. Since then medical men living as widely apart as Staines, Alloa, Liss, Royston, Folkestone, Brockenhurst, and Hawick have written to say that they can let our correspondent have copies of the book.

Income Tax

Depreciation of Sun-ray Apparatus

"T. D. R." has claimed an allowance of 20 per cent. of the cost (£65) of a sun-ray apparatus, but the inspector of taxes will agree to 5 per cent. only.

So far as our knowledge goes 10 per cent. is the usual rate allowed. Electrical appliances are undoubtedly subject to heavy depreciation, and 5 per cent. is definitely inadequate.

Request for Audit of Accounts

"E. R." is a partner in a firm whose annual accounts are prepared on a model furnished by a London firm of accountants, and have hitherto been accepted for income tax purposes without question. A request has now been made for the accounts to be audited.

It is, of course, fairly common for a firm's accounts to be prepared annually by a qualified accountant, but it is most unusual for a request of the sort mentioned to be made where there are no special circumstances. Professional accounts are so much simpler to keep and to summarize than business accounts that the usual possibilities for error are comparatively small. We suggest that "E. R." should see his local inspector of taxes, point out to him the unusual nature of the request, and ask for what reason the certificate of the partner who prepares the account is considered inadequate.

LETTERS, NOTES, ETC.

Epsom College Founder's Day

Favoured by fine weather, and attended by over 1,500 guests, Founder's Day was celebrated at Epsom College on Saturday last, July 28th, when the new president, Lord Leverhulme, presented the prizes. Proceedings opened at 11 o'clock with the second day of the Past and Present cricket match, which (for the first time for over ten years) was won easily by the Old Boys, who had no fewer than seven former school captains in their side. Service was held in chapel at noon. After lunch spectators were treated to a well-varied and effective open-air assault-at-arms, and this was followed by the prize-giving in Big School. The headmaster, in his speech of welcome to Lord Leverhulme, referred to a satisfactory year's progress, which had been rounded off by a striking improvement in examination results. He enumerated the additions made to the school buildings during the year, and announced that the council had decided to put up a block of new class rooms, ablution rooms, and changing rooms on the site of the present old chemistry block. If the school could shortly get some squash courts, there should then be no need for further building for many years. The headmaster also announced that a representative of the Ministry of Health had spent a week of the summer term at Epsom College investigating the diet and muscular reactions of the boys, and he felt sure the data, when collated, would be interesting and of good purpose both to the Ministry and to the school. Lord Leverhulme, after presenting the prizes, in the course of an interesting and witty speech emphasized the necessity of encouraging a boy to follow his bent. In the evening the school choral and orchestral societies gave a performance of *H.M.S. Pinafore*.

High Therapeutics

Mr. J. D. P. GRAHAM (Glasgow) writes: Those practitioners who pride themselves on keeping up to date in their therapeutic methods may care to add the following procedure to their technique. A lady infant health visitor in the city here was concerned to learn that a certain child among her charges was suffering from bronchitis. She therefore made haste to pay a visit and inquire after the invalid. The weather was extremely hot. The mother seemed unduly reluctant to allow of the visitor's looking at the youngster, but finally her excuses were overcome, when the lady approached and was shocked to discover a ghastly smell as of putrefaction coming from the region of the child. Further investigation revealed a large piece of fat applied to the unfortunate child's chest. Unashamedly the mother explained that a piece of chicken fat tied on the "affected part" was a sovereign specific for all coughs, though in hot weather it had its disadvantages.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 35, 36, 37, 38, 39, 42, and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 40 and 41.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 112.

BRITISH MEDICAL JOURNAL

LONDON: SATURDAY, AUGUST 11th, 1934

ENCEPHALITIS *

BY

W. G. WYLLIE, M.D., F.R.C.P.

PHYSICIAN TO OUT-PATIENTS, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET

The subject of encephalitis is specially suitable for the section of diseases of children because in so many of its forms it is the period of childhood which is principally affected. The term "encephalitis," however, must be interpreted in its broadest sense. It is used to cover a large and heterogeneous variety of conditions, some inflammatory, others toxi-degenerative, and others of a vascular nature—embolic, haemorrhagic, and thrombotic. For the clinician it is often impossible to make a pathological diagnosis with any certainty, as the symptoms presented by the patient can only indicate which parts of the brain are involved, and may be produced by a variety of causes.

In the first place, we recognize two main types of encephalitis—the suppurative and the non-suppurative. About the former, suppurative encephalitis or cerebral abscess, it is sufficient to say that it is due to an invasion of the central nervous system by pyogenic organisms, and is almost invariably secondary to infection of the middle ear and mastoid, or a complication of chronic pulmonary

Non-suppurative encephalitis covers a much wider field, and contains the bulk of our material. The last twelve years, since 1922, have been specially eventful in increasing our knowledge of the clinical and pathological aspects of encephalitis. The stimulus provided has been the wave of prevalence of spontaneous forms of meningo-encephalitis, and of nervous complications following vaccination and some of the exanthemata. Earlier in the present century, starting from about 1916, the world-wide spread of epidemics of encephalitis lethargica constitutes a separate and distinct event. Prior to these two epochs encephalitis occupied comparatively little space in medical literature, and, with the exception of polio-encephalitis, is mainly referred to under purely clinical titles, such as sporadic cases of acute hemiplegia, acute tremor, and acute ataxy.

I propose to review briefly the various types of encephalitis in the following order: encephalitis lethargica and polio-encephalitis; encephalitis as a complication of vaccination, the acute fevers, and exanthemata; and acute disseminated encephalo-myelitis of spontaneous onset.

Encephalitis Lethargica and Polio-encephalitis

Encephalitis lethargica and polio-encephalo-myelitis stand out as distinct and separate entities—diseases of virus causation, with a clear-cut pathology, and without relation to any of the other forms of encephalitis. The neurotropic virus of encephalitis lethargica has a predilection for the grey matter of the brain stem and basal

ganglia, though no part of the nervous system is exempt. In polio-encephalitis, which, compared to the spinal type, poliomyelitis, is undoubtedly a rare disease, the activity of the virus falls focally upon the grey matter of the cortex, less often the brain stem and cerebellum.

The symptoms of "sleepy sickness" are too well known to need much comment. In the epidemics of past years an acute stage was frequently observed, typified by lethargy, disturbance of the sleep rhythm, ocular paralyseis, myoclonic and choreiform movements of the limbs. Characteristic symptoms of the chronic stage are lethargy, mental changes, and Parkinsonian rigidity. Mental deterioration in intelligence and behaviour are specially common in cases occurring in early childhood. In recent years, since 1926, the prevalence of the disease has markedly declined, and an acute stage is now rarely witnessed, or is of so mild a nature that its significance escapes recognition. A few cases in the chronic stage still come to light, in children as well as in adults.

To make a diagnosis of polio-encephalitis in the absence of polio-infection in epidemic proportions is probably nearly always inaccurate. The predilection of the polio-virus for the grey matter of the spinal cord has been proved experimentally beyond any doubt. Cerebral lesions, either in man or in animals, are unusual. Even in epidemics of poliomyelitis the cerebral type of case will not account for more than 4 per cent. of the total. The usual syndromes of polio-encephalitis are a sudden onset of fever, vomiting, convulsions, and coma, with a residuum of hemiplegia, sometimes accompanied by mental defect and epilepsy, or the main symptom may be cerebellar ataxy. These syndromes, however, are common to so many types of encephalitis, following acute fevers, the exanthemata, and of spontaneous onset, that in sporadic cases the clinician can seldom be certain of their pathology.

The frequency with which a diagnosis of polio-encephalitis is made in cases of acute hemiplegia in young children dates back to 1884. In that year Strümpell published a paper, based on twenty-four cases, in only two of which was the condition a complication of measles and of scarlet fever. He cited the uniformity of the symptoms with motor paralysis, the healthy type of child affected, the early age of onset (nineteen out of twenty-four cases in the first three years of life), and claimed that the condition was a specific disease, infective in origin, closely analogous to spinal paralysis or poliomyelitis. His opinion was supported by Marie and others, but queried by Wallenberg, who remarked that, although the symptomatology of acute hemiplegia in children was sharply defined, its morbid anatomy possessed no characteristic lesion. Gowers also opposed the theory, and stated that encephalitis of the Strümpell type was a "theoretical disease."

* Read in opening a discussion in the Section of Paediatrics at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

Encephalitis Associated with Vaccination and Acute Fevers

The group of encephalopathies associated with the acute fevers, exanthemata, and vaccination has been intensively studied within recent years. These nervous complications have long been recognized as rare occurrences, but actually since 1922 the cases following vaccination, measles, small-pox, and chicken-pox have been more numerous.

The clinical syndromes of the encephalopathies following vaccination, the acute fevers, and exanthems are of several types, but some types tend to be more often associated with certain fevers than with others. A meningeal syndrome, or state of meningismus or serous meningitis, with headache, vomiting, cervical rigidity, Kernig's sign, and sometimes convulsions, may be observed in any of the fevers. Other syndromes are: (1) a combined cerebral and spinal type; (2) a mainly spinal type; (3) a cerebellar and ataxic form; and (4) a focal cerebral hemiplegic type.

After vaccination, measles, and small-pox the combined encephalo-myelitic and the mainly myelitic syndromes are most common. Cerebellar ataxy, less often spinal symptoms, are seen following chicken-pox. In the much rarer cases following German measles, cerebral, cerebellar, and spinal symptoms have been recorded. The focal hemiplegic syndrome is the commonest complication of whooping-cough, scarlet fever, and mumps.

The nervous complications of vaccination, measles, small-pox, chicken-pox, and German measles have many features in common. This family likeness is noticeable in the symptomatology, the uniformity of the time interval, or period of incubation, separating the primary exanthem and the nervous symptoms. Further, the occurrence of nervous symptoms seldom bears any relation to the severity of the primary exanthem, or to the size of the epidemic.

The sequence of events is generally as follows. Usually after a period of about seven days, and after a febrile period of decline of the primary exanthem, when the patient is afebrile, the nervous symptoms appear abruptly with a renewal of pyrexia. Meningeal symptoms are commonly present, and drowsiness is a prominent symptom, often deepening to coma, which may last for several days. On the return of consciousness the character of the paralysis becomes more obvious. In the encephalo-myelitic type multiple focal signs of involvement of the brain and spinal cord are observed, including diplegia, hemiplegia, and aphasia, choreiform movements, rigidity, tremor, difficulty in speech and in swallowing, absence of the knee- and ankle-jerks, with extensor plantar responses. Trismus is often observed. Ocular paralyses and nystagmus are uncommon, but some swelling of the optic disks is frequently present. In the cerebellar type the predominant feature is ataxia. The character of the spinal type is that of a transverse or an ascending myelitis, with sensory disturbances and retention of urine.

Some reference must be made to the relative frequency of these complications. The case records, prior to the last twelve years, have been very few in number, and the instances of post-varicellar complications still rarer. Dagnelie, van Bogaert, and others have estimated from the literature a total of sixty-nine cases following chicken-pox, of which fifty have occurred since 1920, with thirteen in the year 1930 alone. In measles the figures have shown a striking rise since 1924. In England for the four years 1927 to 1930 of fatal cases alone there have been twenty-five. Post-vaccinal encephalitis began to be more frequent in 1922. From 1922 to 1927 the total of cases in Holland was 170, in England and Wales ninety-three, of which nine were in infants under 1 year. A raised incidence has been reported in nearly all European countries and in America. This prevalence, however, must not be exaggerated,

for, as Rolleston states, "the proportion of cases with nervous sequels was 1 to every 33,000 vaccinations, and of deaths, 1 to every 66,000 vaccinations." Since 1929 the number of cases following vaccination has markedly diminished. Following small-pox, mostly of the modified type, a slight increase of nervous complications has occurred. Marsden and Hurst described ten cases out of 40,313 cases of small-pox notified in England and Wales between 1928 and 1931. With one exception the ages in the group were all below 15 years.

The mortality rate in the cases following these fevers is unequal. It is least in the post-varicellar cases—about 6 per cent. In the cases following measles Ford estimates the mortality at about 10 per cent., and in post-vaccinal cases the average mortality has been 30 to 40 per cent. Otherwise the prognosis is good, and recovery usually complete, though some form of paralysis, or a psychosis, such as a speech disturbance, aphasia, or abnormal behaviour, may linger for a while. A permanent incapacity of some form has apparently been more common in the cases following measles than after vaccination or chicken-pox.

In scarlet fever, encephalitis, usually of the hemiplegic type, may occur early in the fever or not until later in the period of desquamation. The nervous symptoms in whooping-cough are often delayed until after the period of paroxysmal coughing has practically ceased. Usually the syndrome consists of multiple convulsions, or whooping-cough eclampsia, in some cases accompanied by hemiplegia, diplegia, idiocy, and blindness (Baginsky, Schmitt, Turnowsky). Most cases of pertussis eclampsia are fatal, but in a few instances recovery has occurred, even with return of vision and disappearance of hemiplegia. Symptoms of meningitis or of meningo-encephalitis, with Symptomatic and meningo-encephalitic complications may also occur in many other acute infections, such as pneumonia, erysipelas (Eckel), streptococcal pharyngeal and otitic inflammation. I have seen complete recovery occur in a case of this type following a streptococcal infection of the throat and middle ear in a boy of 7 years. It is interesting to note that Freud, in 1897, stated that hemiplegia in children occurred after infective corneal inflammation. The following order of frequency: measles, small-pox, German measles, whooping-cough, diphtheria, mumps, and vaccination.

Broadly speaking, the pathological features of the encephalopathies following vaccination, the exanthemata, and other fevers are of two main types. In one the principal points are congestion, oedema, vascular endothelial proliferation, and ganglion cell degeneration. This type is known as acute toxic encephalitis, and sometimes as acute haemorrhagic encephalitis with the presence of microscopical extravasation of red cells in relation to the vessels. The distinctive feature of the other type is the presence of areas of demyelination around the small veins, chiefly in the white matter—demyelinating encephalitis. Toxic encephalitis is the form usually associated with whooping-cough and acute infections, such as pneumonia and streptococcal tonsillitis and otitis media. Some cases of scarlatinal meningo-encephalitis are of this kind, and it has also occurred in association with measles and small-pox. The onset of symptoms, however, in cases of this nature complicating measles and small-pox shows no typical incubation period, but may even precede the appearance of the rash. Toxic encephalitis is almost certainly a reaction to bacterial toxins rather than the result of a microbic invasion. Grinker and Stone have drawn attention to the fact that the characteristic cerebral vascular, endothelial proliferation, and ganglion cell degeneration has also been observed in cases of food poison-

Aug. 11, 1934]

ing, and can be produced experimentally by inorganic poisons. A purely meningeal syndrome, or serous meningitis, can also be produced by a toxæmia. Blühdorn describes ten such cases in children, three complicating pneumonia, two whooping-cough, and five of spontaneous onset.

The endotoxin of whooping-cough has been shown experimentally in guinea-pigs by Fonteyne and Dagnelie to have a highly toxic action in minute doses injected intracerebrally. An intense convulsive state was provoked with a rapidly fatal meningo-encephalitis. Dubois, Ley, and Dagnelie, in eight fatal cases of whooping-cough, found fairly distinctive anatomical changes, consisting of small-celled meningeal infiltration and toxic degenerative changes of the ganglion cells. In none of these cases had hæmorrhage occurred.

Vascular lesions as a cause of hemiplegia in whooping-cough and scarlet fever have in the past acquired an importance which cannot be justified. It is possible in whooping-cough in the early stages, during a particularly severe bout of coughing, that asphyxia may lead to vascular stasis, cerebral oedema, and even hæmorrhage, resulting in a temporary or permanent hemiplegia. I have seen cases of hemiplegia, presumably of asphyxial origin, both in whooping-cough and in asthma, and in each instance the paralysis entirely cleared up.

The second pathological type, or demyelinating encephalitis, is characteristic of the cases of encephalo-myelitis following vaccination, measles, small-pox, chicken-pox, and German measles. The origin of this demyelinating reaction has yet to be solved—whether it is due to the action of the virus of the primary exanthem itself, or due to toxins, or to a latent hypothetical virus stirred into activity by any of these fevers. In vaccination experimental research has failed to reproduce lesions analogous to the demyelinating encephalitis seen in man. Hurst states that the lesions produced in the nervous system by vaccine virus are of a totally different type.

Spontaneous Acute Disseminated Encephalo-myelitis

Under this title several conditions are grouped which present cerebral, spinal, and meningeal symptoms, either combined or separately. They arise independently of the acute fevers or exanthems, or of any known cause. One form is clinically and pathologically indistinguishable from the cases of encephalo-myelitis following vaccination and measles. It shows the same demyelinating feature. Hurst considers that it should be regarded as an independent clinical and pathological entity, whether following one of the fevers or arising spontaneously. The spontaneous cases within recent years have occurred in children and young adults, and if the condition existed formerly it was either unrecognized or excited little interest.

Another form resembles in both clinical and pathological features the toxic encephalitis complicating acute infections—pneumonia, tonsillitis, and scarlet fever. It has been described under several titles: acute meningo-encephalo-myelitis of childhood, acute toxic or serous encephalitis (Brain and Hunter, Brown and Symmers), Both sporadic and epidemic cases have been recorded. Recovery is often complete in non-fatal cases, but the mortality has varied in different epidemics. In Brown and Symmers's ten cases of "acute serous encephalitis," aged 2 years and 2 months to 7 years, all died. Cases of a mainly meningeal type have been described as "epidemic serous meningitis," or "epidemic meningitis minor" (Schlesinger, Braithwaite and Innes). In Braithwaite and Innes's series of thirteen cases in children between 9 weeks and 6 years old, five were spontaneous and six secondary to mild bronchopneumonia.

It is difficult to know where to fit in the spontaneous cases in young children of acute tremor, acute ataxy, and acute hemiplegia, of which there are a large number of records in the literature (Poynton, Miller). Very little is known of the pathology of these conditions, as they are seldom fatal, and their causation is obscure, though they are possibly of toxic origin. In the cases of acute ataxy, and of acute tremor with hypertonus, nystagmus, and scanning speech, recovery is usually complete. In the cases of acute hemiplegia the paralysis is permanent, and often accompanied by amentia and epilepsy. This condition occurs chiefly in healthy young children, most often in the first three years of life (Taylor, Osler), and early symptoms are fever and a convulsive state, lasting for several days or longer. In such a case, which succumbed to bronchopneumonia, I had the opportunity of making a post-mortem examination, and found a thrombosis of one anterior cerebral artery, with no evidence of arterial disease elsewhere.

The Cerebro-spinal Fluid.—In all these forms of non-suppurative encephalitis the state of the cerebro-spinal fluid is fairly uniform. It may be normal, or show a slight rise in the protein percentage and a small or moderate increase of cells, which are mainly lymphocytes. Occasionally a turbid fluid is encountered, especially in the cases following measles, and polymorphs may predominate. A diagnosis of tuberculous meningitis is apt to be made in the early stages, but on subsequent lumbar punctures the persistence of normal percentages for the chlorides and glucose excludes this possibility.

Treatment.—Besides its diagnostic use, lumbar puncture is of value in alleviating the symptoms, and should be performed daily in the acute stage. Convalescent sera in the cases following vaccination (Horder, Hekman), and after measles and chicken-pox, have been used with apparent success, but the use of these sera must be empirical until more is known of the causation of these nervous complications.

Major G. D. Jameson, R.A.M.C., in his annual report to the Gibraltar City Council, states that the general health of Gibraltar was good in 1933, when the zymotic death rate was the lowest recorded during the past decade. The infantile mortality rate was lower than in any previously recorded year. During a short period in the autumn, water for drinking purposes was supplied from wells at North Front to supplement the existing rain-water supply. This water was chlorinated before distribution, and the scheme worked successfully.

TYPHUS FEVERS IN THE TROPICS*

BY
SIR JOHN MEGAW, K.C.I.E.
MEDICAL ADVISER TO THE INDIA OFFICE

The title of the present discussion is "Tropical Typhus," but this name is obviously inappropriate, as the fevers with which we are dealing occur just as frequently in cold countries as in hot. A more suitable name is "Typhus Fevers in the Tropics," and although some experts are sure to object, I will adopt this until something better is suggested.

I propose to deal with the typhus fevers very briefly and in an elementary manner from the historical, clinical, and epidemiological points of view. I shall make little reference to the virus of the fevers: this omission is not due to any lack of appreciation of the very valuable contributions made by laboratory workers to our knowledge of these diseases, but to the fact that Dr. Fletcher and Dr. Felix, who have done so much to elucidate this aspect of the subject, are expected to take part in the discussion. My remarks are intended to provide a sketchy background to the very interesting observations which they are sure to make.

Typhus as an Epidemic Disease

"Every schoolboy knows" that the name "typhus fever" was originally applied to typhoid and relapsing fever as well as to typhus. In 1837 Still and Gerhard showed that typhoid fever was a distinct disease, and in 1843 Henderson differentiated relapsing fever. In 1862 Murchison emphasized the contagious nature of typhus fever. Nicolle and Conseil, in 1909, proved that the disease could be conveyed by lice. Between 1906 and 1910 Ricketts and Wilder suggested that the bodies now known as Rickettsia bodies were the causal organisms of typhus fever and Rocky Mountain spotted fever. In 1910 Wilson of Belfast discovered that the sera of typhus patients agglutinated organisms of the *coli* group which had been isolated from cases of the disease. He was careful to point out that he did not regard this agglutination response as indicating that the organisms caused typhus fever. Weil and Felix in 1916 described the reaction which is now known by their name; they used an organism called "*Proteus* X 19."

Until recently typhus exanthematicus was regarded as being essentially different from the other fevers which resembled it so closely in their clinical features; the reason being that these fevers were in sharp contrast with typhus in not being epidemic diseases associated with crowding, poverty, filth, and lice, and in not being directly communicable from man to man. Accordingly, even the spotted fever of the Rocky Mountains, which closely resembles typhus, was regarded by nearly all observers as belonging to a different disease group, until Wolbach, in his masterly monographs on the subject in 1916 to 1919, showed the essential similarity in the pathology of these two fevers. Sambon, however, had previously insisted that they were really the same as typhus fever.

So long ago as 1897 Brill of New York had discussed the relation between the disease which now goes by his name and typhus fever; he concluded that the epidemiological differences were so great as to make it impossible to place the two fevers in the same group, but in 1912 Brill's disease came to be regarded as an inter-epidemic form of typhus, because its virus was found to protect animals against typhus.

TYPHUS FEVERS IN THE TROPICS

[THE BRITISH MEDICAL JOURNAL]

At this date the position was that typhus fever was regarded as a unitary disease, while the Rocky Mountain and Japanese fevers were considered as belonging to a different category; they were known to be communicated from rodents to man by ticks and mites respectively.

Insect Vectors in other Diseases Resembling Typhus

A brief reference must be made to some fevers, the aetiology of which was not known at first, but which are now recognized as belonging to the typhus disease group. In 1910 Smithson in Queensland described a fever resembling Brill's disease; he suspected that the vector was some insect living in sugar canes. The same year Conor and Bruch described a similar disease in Tunis, and called it "fièvre boutonneuse." In 1911 McNaught gave an account of an anomalous form of paratyphoid occurring in South Africa. In his report he makes a significant reference to a suggestion by Colonel Maher that the fever might be connected with ticks, since he found that the onset of the patients had been bitten by ticks prior to the report. McKechnie, in 1913, wrote a very interesting report, unfortunately never published, of a fever prevalent in one locality in the Kumaon region of the lower Himalayas. He called this fever typhus, and suggested fleas, bugs, and mosquitos as possible vectors. Two years later, in 1915, Schüffner described a pseudo-typhus fever in Sumatra, and suspected a tick or mite of being the vector. The name given by Schüffner would probably be more correctly translated into English as pseudo-typhoid, as I understand he was thinking of typhus abdominalis rather than typhus exanthematicus.

Non-Epidemic Typhus in India

My own experience of a non-epidemic typhus fever was thrust upon me rather than sought. In June, 1916, while in the near neighbourhood of the place where McKechnie had already reported his cases of typhus, I found a tick on my neck in circumstances which indicated that it must have attached itself about twelve hours earlier. Some twenty days later, after returning to Lucknow, I began to suffer from fever with a step-like rise in temperature; within four days an eruption appeared, which recalled to my mind the descriptions I had read of the Rocky Mountain fever. At that time no human disease was known to be conveyed by a tick in India, so I had light-heartedly thrown away a very interesting specimen which, within a few days, assumed considerable importance as being the only likely vector of my attack of fever.

I wrote an account of my case in the *Indian Medical Gazette* of January, 1917, in which I suggested that the tick must have been either *Rhipicephalus sanguineus* or *Hyalomma aegypticum*. This, I think, was the first case in which definite evidence was produced of a tick being the vector of a typhus-like fever outside the Rocky Mountain fever zone. I also suggested that McKechnie's Kumaon fever and the fevers described by Conor, McNaught, and others should be classed with the spotted fever of Idaho and Brill's disease as a subgroup of typhus fever, differing from that fever in being conveyed by ticks or fleas, in being place diseases, and in having no connexion with lice, famine, dirt, or overcrowding. I fell into one serious error in regarding the low virulence of these diseases as being an important feature in differentiating them from classical typhus, but apart from this I have nothing to retract from what I wrote there eighteen years ago.

Several readers of my note, including Major-General Sprawson and Colonel Chapman, sent me accounts of similar cases which they had observed in various places in India. On the strength of these reports and after further study of the subject, I felt justified in suggesting

* Read in opening a discussion in the Section of Tropical Diseases at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

in a paper published in the *Indian Medical Gazette* of October, 1921, that a fever conveyed to man from an animal of the wilds by a tick was widely distributed in India and probably in other parts of the world; that this could not be clearly distinguished from the Rocky Mountain fever; and that it, with the other sporadic typhus-like diseases, should be classified as members of the typhus fever group. Accordingly, I suggested the classification "louse typhus," "tick typhus," and "mite typhus." In later papers I produced evidence of the frequent occurrence of tick typhus in various parts of India as well as in other countries, and added to my previously proposed classification another heading—namely, "typhus of unknown vector."

Fletcher's Work in the Federated Malay States

Apart from work in the Rocky Mountain, Japanese, and Indian areas, there was little evidence of interest in the sporadic typhus fevers until 1926, when Dr. William Fletcher described a number of cases of "tropical typhus" in the Federated Malay States. Dr. Fletcher was struck with the resemblance between his cases and those described by me in India, but he found no evidence of tick bite, and the agglutination response to *proteus* X organisms was quite different in his cases from that observed in India. In the Indian tick typhus the Weil-Felix reaction was usually negative, or positive only in such dilutions as 1 in 80 or 1 in 100 to *proteus* X 19, whereas Fletcher found two sharply contrasted groups of cases, one of which gave a strongly positive reaction to *proteus* X 19 and was negative to the Kingsbury strain of *proteus*, while the other reacted to the Kingsbury strain of *proteus* X but was negative to *proteus* X 19. At first the differences between the two forms of tropical typhus and tick typhus were rather puzzling, but recent work indicates that there really are three distinct types of sporadic typhus—namely, tick typhus, mite typhus, and flea typhus—and that each of these shows a distinct characteristic agglutination response towards *proteus* X organisms.

Apart altogether from its great intrinsic value, Dr. Fletcher's report was very important in attracting the attention of the medical world to these sporadic typhus fevers. Within the past few years a vast number of observations have been published showing that the fevers of the typhus group are very widespread in their distribution and of considerable practical importance.

It was not until 1930 that Durand, Conseil, and Brumpt demonstrated the conveyance of "fièvre boutonneuse" by a tick, *Rhipicephalus sanguineus*, which was one of the two suspected by me in 1916. Now we know also that the form of sporadic typhus which conforms to Brill's description is conveyed from rats to man by fleas, so that to my previous provisional classification there must now be added another subgroup—"flea typhus."

Need for Uniform Nomenclature

A few words must be said on the subject of the classification of the typhus fevers. Dr. E. W. Goodall objected to Dr. Fletcher's use of the name "tropical typhus," on the ground that all the typhus fevers ought to be called typhus pure and simple, irrespective of the vectors concerned and any other differences that exist between them. While I object to the name "tropical typhus," I object much more strongly to the position adopted by Dr. Goodall, for although the sporadic fevers are very similar to louse typhus in their clinical and pathological features, they are poles asunder in their epidemiology and in the measures that are called for in their practical management. If the name "typhus" were applied to all fevers of the group without further

qualification a very misleading suggestion would be conveyed.

Disease nomenclature is intended to be helpful to the medical man, and should be as simple as possible, but if we attempt to secure simplicity by lumping together things that are essentially different the only result will be confusion. The classification of the typhus fevers is a matter of real importance, and I take this opportunity of appealing once more for the adoption of a uniform and rational nomenclature. The need for this step is evident when we consider that more than a dozen different names were given to the sporadic typhus fevers in a single recent issue of the *Tropical Diseases Bulletin*. Here is an incomplete list of twenty-seven names which have been used during the past few years for these fevers: spotted fever of the Rocky Mountains, fièvre boutonneuse, fièvre exanthématique, fièvre escharo nodularis, eruptive fever, macular fever, Marseilles fever, jungle typhus, spotted fever of the Eastern type, tick-bite fever, tick fever, Brill's disease, tropical typhus, endemic typhus, sporadic typhus, shop typhus, ship typhus, murine typhus, tabardillo, Mexican typhus, flea typhus, Manchurian typhus, Japanese river fever, tsutsugamushi, pseudo-typoid of Deli, Mossmann fever, and mite typhus. This is an appalling list, the only redeeming feature of which is the growing tendency to use the name typhus. Place names are obviously unsuitable; they suggest that the disease is restricted to one locality—for example, I could not have described Indian tick typhus as Rocky Mountain fever. Names like "spotted" or "macular" are also unsatisfactory; there are so many fevers in which spots or macules appear that the name becomes meaningless.

My provisional suggestion that the word typhus qualified by the name of the vector should be employed was open to criticism, because the vector was often unknown or doubtful. This perfectly sound objection can only be met by a frank confession of ignorance when the actual vector is unknown or doubtful, and accordingly employing the non-committal general term "non-epidemic typhus" to indicate those fevers which are not conveyed from man to man by lice as contrasted with "epidemic typhus," which has a human reservoir of infection. The term "endemic" would be neater and better than "non-epidemic," but it has already been earmarked as a name for flea typhus, and therefore could not be used without risk of confusion.

Suggested Classification

Evidence is now accumulating to show that the specific agglutination response of each of the non-epidemic typhus fevers is associated with the vector concerned, so that we may soon be able to classify the fevers according to the vector, even when there is no direct evidence as to which arthropod is responsible in any given case. With the rapid accumulation of more knowledge of the geographical distribution of the fevers, difficulty in assigning each case to the appropriate vector should soon disappear. Until something better is proposed I therefore suggest the following modification of my original classification.

This classification is not ideal, since, apart from the occasional difficulty of determining which vector is concerned, we are not yet able definitely to state that there are four distinct types of virus. In louse, tick, and mite typhus the evidence is already fairly strong that each

THE MEDICINAL TREATMENT OF CHOREA
(CALCIUM ASPIRIN)BY
N. MUTCH, M.D., F.R.C.P.
PHYSICIAN TO GUY'S HOSPITAL

Discussion will be confined to chorea of Sydenham's type in children. Debatable cases of adult hysteria, pregnancy chorea, and conditions such as Huntington's chorea with gross structural changes in the central nervous system have been excluded.

General Considerations

The anatomical basis of the disease is still uncertain, and such changes as have been described are attributable to pyrexia, capillary emboli from coincident endocarditis, or confusion in diagnosis with the choreiform varieties of epidemic encephalitis. The basal difficulty is that in its typical form Sydenham's chorea is not fatal. Practically all recorded post-mortems have been carried out on cases of rheumatic endocarditis and pericarditis complicated by chorea, and not on patients dead from chorea itself. The most careful histological research, with modern methods on a typical case, by Shaw²³ did not reveal any morbid changes other than simple hyperaemia. It can be assumed, therefore, that the anatomical changes are negligible, and not such as to preclude complete recovery. If the patient is suitably rested and cared for, the spontaneous recovery rate approaches 100 per cent., so that the effect of a drug can only be assessed in terms of its ability to lessen the duration or severity of the attack. The average duration is usually accepted as six to ten weeks, but some cases drag on for months. For greater discrimination some method of grouping is essential.

1. Mild chorea, in which speech is not definitely affected and the patient can feed and dress himself with more or less difficulty.
2. Moderate chorea, in which coarse voluntary movements can still be performed, but the patient cannot feed or dress himself.
3. Severe chorea. Violence or pseudo-paresis now prevent all purposeful voluntary action. Bed boards and other protective measures are required.

Adopting a somewhat similar grouping Sutton²⁹ records sixty-three undrugged cases.

Group	Average Duration	Extremes
1. Mild	35 days	10-65 days
2. Moderate	46 "	19-120 days
3. Severe	67 "	30-180 days

The general average was 47 days.

There is no reason to believe that the general characteristics of the disease have undergone any material change in the last eighty or ninety years. Already by 1846 H. M. Hughes⁷ had dealt with the matter at Guy's. A few years later Séé²⁷ recorded an extensive clinical and aetiological analysis in Paris, and Trousseau discussed it at the New Sydenham Society. In 1874 Pye-Smith²⁴ reviewed the Guy's Hospital figures again, and in 1897 Morley Fletcher¹⁴ did the same at St. Bartholomew's. The chief clinical features have remained constant throughout. The disease has persistently occurred about three times as commonly in females as in males. The age of maximum incidence has always been between eight years and puberty. Urban districts have been more affected than the country, and the association with articular rheumatism and inflam-

virus is different from the others; at any rate there is no case on record of direct communication of tick or mite typhus from one person to another, and, after all, the manner of conveyance of the diseases is by far the most important practical matter from the physician's point of view. Flea typhus is so closely related to louse typhus in its immunological and serological aspects that careful research will be needed to determine whether or not the virus of louse typhus can ever be transmitted by fleas. If this virus be transmissible by fleas it must be greatly attenuated in the process, since flea typhus is the one type which has never been found to be severe. There is no evidence that any of the non-epidemic typhus fevers has ever started in a louse-borne epidemic, so that although there may be some mental reservations regarding the relation of the fevers, practising physicians can safely base their action on the hypothesis that epidemic and non-epidemic typhus fevers are essentially distinct from each other.

Differential Diagnosis

I have already referred to the error into which I fell eighteen years ago with regard to virulence; the truth is that tick typhus and mite typhus may be very mild or very severe. The same applies to a lesser extent to louse typhus, which is sometimes quite mild. Flea typhus alone has a consistent record of mildness so far, although severe or even fatal cases have been recorded. Another point which is sometimes relied on for differential diagnosis between the various forms of non-epidemic typhus is the presence or absence of local necrosis at the site of infection associated with lymphangitis. This feature is sometimes present and sometimes absent, both in tick typhus and mite typhus; it cannot, therefore, be relied on as a point of distinction between the two fevers. Agglutination and animal inoculation tests are not always conclusive, so that when there is no positive evidence regarding the vector difficulty may arise at times in individual cases in distinguishing between the three types of non-epidemic typhus.

On the other hand, there will seldom be any difficulty in deciding whether any given fever belongs to the epidemic or non-epidemic group if all the circumstances of each case or outbreak are investigated. After all, the chief concern of the medical man is to decide whether he is dealing with a disease which calls for extremely careful precautions to prevent spread to other human beings or with a disease not communicable from man to man.

Serological tests against two or more varieties of *proteus* X organisms will often be of great help in diagnosis, and knowledge of the local conditions will usually make it possible to be reasonably certain of the particular vector which is concerned.

We are now at an interesting stage of the investigation, and with so many intelligent observers at work throughout the world we seem to be rapidly approaching the time when the non-epidemic typhus fevers will be completely rescued from the small and rapidly diminishing group of fevers of unknown or doubtful aetiology. The most astonishing feature of the non-epidemic typhus fevers is that they escaped recognition so long in many parts of the world, in spite of their striking and characteristic features.

Volume XII of the *Guide to Current Official Statistics of the United Kingdom* is now available. It contains a list of the titles and prices of the statistical volumes issued during 1933 by the Governments of Great Britain and Northern Ireland, and an alphabetical index of their contents. Copies can be obtained from H.M. Stationery Office (1s. net, 1s. 5d. post free).

mation of the heart has been uniformly common. The mortality has been steady at about 2 per cent. If these facts are borne in mind it becomes comparatively easy to discard most of the older methods as powerless to change the general course of the complaint.

Therapeutic Measures

Methods have been varied and ingenious, and routes of administration many.

By Mouth.—Sodium salicylate, arsenious oxide, mercury, antipyrine, aspirin, chloral, chloretone, trional, bromides, luminal, nirvanol and other hypnotics, thyroid, parathyroid, and iodine.

Subcutaneously.—Adrenaline, sodium cacodylate, Rosenow's antiserum, and varieties of antistreptococcal sera.

Intravenously.—Novarsenobenzol, hypotonic saline.

Intramuscularly. Sulpharsphenamine, milk, typhoid vaccines, and T.A.B.

Intrathecally.—Magnesium sulphate, colloidal silver, gentian-violet, 1 per cent. phenol, atoxyl, sodium salicylate.

Per Rectum.—Avertin and paraldehyde.

Various Measures.—The removal of tonsils and other foci of sepsis and irritation; the ketogenic diet.

Although most of these methods can be dismissed as useless a few call for special discussion.

NIRVANOL

Nirvanol, or phenyl-ethyl-hydantoin, a near relation of the barbiturates, was first introduced as a hypnotic, but soon discredited because of its great tendency to produce skin eruption. It was reintroduced in 1919 by Roeder,²³ in Germany, as a specific for chorea. Her results were confirmed in Germany (1924-5) by Schmal,²⁴ E. Hefter,⁴ and Husler,⁵ and subsequently by a host of workers in Germany, America, and England. Even in 1932 its praises were still sounded, thirteen years after its introduction (Dennett and Wetchler¹). It would appear to be quite established as a drug which shortens the attack in a useful proportion of cases, in spite of the adverse report from a minority of clinicians—for example, Weinfeld and Cohen.²⁵ The treatment is drastic. A week is occupied in saturating the patient with the drug. Then follows a period of fever, rash, and severe constitutional disturbance. The method is not free from risk, and a certain number of deaths have been attributed to its use. It may cause serious leucopenia, loss of platelets, purpura, mucosal haemorrhage (Jones and Jacobs⁹), bloody diarrhoea, jaundice (Keller¹⁹), severe lung complications (Piltz,²² also Jones and Jacobs⁹), and damage to the kidneys (Pilcher and Gerstenberger²¹).

These universally disagreeable and sometimes dangerous side actions preclude any general employment of the drug in private practice. In my personal experience the biochemical trauma produced by the drug has impressed me far more than its efficacy in controlling the chorea.

KETOGENIC DIET

Increased muscular excitability in conditions of alkalosis and tetany led to the suggestion that, in a converse manner, hyperexcitability might be depressed by the production of artificial acidosis. With this end in view a diet containing an excessive proportion of fat is given. The ratio of fatty acid to glucose is made 2:1 and graduated until the ratio becomes 4:1. On this regimen acetone quickly appears in the urine, although the pH of the blood and the plasma bicarbonate are not easily modified. Some authors have reported improvement in chorea, but the most recent records by Gerstley and Wile,³ of fifteen closely observed cases, failed to show any advantage in the method at all; such has been my own experience.

PYROGENETIC METHODS

Since the introduction of the malarial treatment for general paralysis in 1918 by Wagner and Jauregg, many other pyrogenic substances have been employed: inoculation with *Treponema hispanicum* and with the organism of rat-bite fever; intravenous injection of typhoid vaccine; and, more recently, intramuscular injections of colloidal sulphur.

Mas de Ayala¹⁵ was probably the first to apply the method in chorea, using *Treponema hispanicum*; but mixed typhoid and paratyphoid vaccine proved much more convenient, and remarkable success has been claimed for this measure by Sutton²⁷ (1931) and by Trawley, Pepper, and Wathe²¹ (1932). About 250 millions of the mixed organisms are injected, and the dose steadily increased daily. A peak of temperature is produced in about three hours, and the temperature is normal four or five hours later. The method appears to cut short the attack effectively. It must, however, be classed as drastic treatment. The patients are decidedly exhausted and anaemic afterwards, and require a considerable period for convalescence (Mandel¹⁴). It is clearly desirable to find some simpler therapy if possible.

Three Aetiological Factors

A consideration of the three commonly recognized aetiological factors—rheumatism, nervous strain, and calcium deficiency—has led me to adopt a gentler type of treatment.

RHEUMATISM

The association between chorea and rheumatic fever is too close to be ignored. Mackenzie,¹² in 1887, recorded a history of rheumatic fever in 26 per cent. of his cases. Morley Fletcher,¹³ in 1896, found the incidence to be 26.9 per cent. among the in-patients at St. Bartholomew's. The corresponding figures for endocarditis among chorea patients are: Hughes (1846), 50 per cent.; Mackenzie (1887), 32 per cent.; Morley Fletcher (1896), 37 per cent.

These figures are still representative of the condition in more modern times. More careful analysis shows also that the severity of the rheumatic lesion varies in parallel with the severity of the chorea. Thus in the same series of chorea cases rheumatic fever occurred in only 19 per cent. of mild out-patient chorea cases, but in 27 per cent. of more severe in-patient types. Similarly, heart murmurs were present in 22 per cent. of mild cases, but in 49 per cent. of those requiring treatment in the wards. The intimate relation between the two conditions can be accepted as established beyond dispute.

NERVOUS STRAIN

It is difficult to discuss this factor on an actuarial basis. A history of fright or of persistent strain from overwork or excitement is given by a large number of the children concerned. The patient is frequently described as alert and bright intellectually before the chorea begins, although powers of attention and application may be seriously impaired later. Sedatives and tranquillity undoubtedly diminish the violence of the movements, even if they do not shorten the attack.

CALCIUM DEFICIENCY

In the latter half of the last century Isambard Owen reported that the topographical distribution of chorea seemed to follow that of rickets, and in 1927 the Medical Research Council¹⁷ reported that general poverty was the only environmental factor which appeared to be operative in the production of the rheumatic troubles of childhood. More detailed analysis proved elusive.

MEDICINAL TREATMENT OF CHOREA

THE BRITISH
MEDICAL JOURNAL

It has long been known that a lack of calcium leads to increased muscular excitability (Biedemann,¹ Loeb,¹¹ Lucas¹²), manifesting itself in spontaneous twitches, rhythmic contraction, and increased sensitiveness to electrical stimuli. The excitability of the motor cortex also rises as the calcium concentration falls. In man a fall in serum calcium leads to increased electrical excitability of the muscles ending in tetany. Recently Carter-Braine, Spurrell, and Warner¹³ demonstrated increased response of the muscles to galvanic stimulation in chorea, and Warner¹³ has correlated this with a deficiency of calcium in the serum and cerebro-spinal fluid. In his series of carefully controlled cases he shows that in active chorea there is always a calcium deficit, that this is greater in severe cases than in mild ones, and that the percentage fall is more conspicuous in the cerebro-spinal fluid than in the blood. In a typical case he found during the height of a severe attack. During the first month no appreciable clinical headway was made, and the calcium value fell a little to 4.62. A month later the attack had subsided completely, and the calcium had risen to 5.74. The normal value from collected data ranges from 5.1 to 6.5 mg. per 100 c.c.m. (Neustaetter,¹⁰ Neale¹⁹). That a disturbance in calcium metabolism occurs in the condition is firmly established, but its causation is still a matter for research.

Calcium Aspirin

In the simple substance calcium aspirin we possess the means of dealing with these three aetiological factors simultaneously. It supplies an adequate amount of calcium, produces a useful sedative effect on the brain, and combats the rheumatic element if given in appropriate doses. The drug has been known for many years, but in spite of its attractiveness has never come into general use, because of its instability. It dissolves readily in water (1 gram dissolves in 5 c.c.m.), in contrast with the neutral solution suitable for administration by vein (Cambell,³ Pritchard,²³ Burnford²⁴) or subcutaneously, as tasteless, and being neutral does not cause the gastric or bladder irritation so commonly observed when aspirin itself is given (Winter and Richey²⁵). Its solubility facilitates absorption (Thompson and Dragstedt²⁶), so that its effects are produced very quickly when given by mouth or rectum.

The difficulty of its instability has at last been overcome. Even simple aspirin exposed to air slowly decomposes with the liberation of pungent acetic acid and irritant free salicylic acid. Contact with water greatly increases the speed of hydrolysis. The simple salts of aspirin contain water of crystallization, which cannot be withdrawn, and hydrolysis is so rapid that the products become unusable before they can reach the patient through the usual channels.³⁰ Coplans has recently shown that this water can be "fixed" by the addition of a small proportion of extra calcium. By crystallization from a solution of calcium chloride a form of calcium aspirin is obtained with a stability approximately equal to that of the parent acid aspirin itself,¹⁶ and completely suitable for general clinical use. Calcium aspirin (Coplans), when taken by the mouth, causes a rise in the calcium content of the blood (Mutch¹⁶). The satisfactory nature of the clinical results can be judged from the following series of hospital and private cases treated during the last three years. The patients were kept in bed, and those treated in hospital were screened off partially from the rest of the ward. Bed boards and other protective measures were

employed as needed. A light, mixed diet was given, and very careful attention paid to the cleanliness of the digestive tract. The only drug employed (exclusive of aperients) was calcium aspirin (Coplans), dissolved in water and administered by mouth. The average daily dose varied up to 45 grains for a child 12 years old. The nineteen cases treated can be placed in the groups already defined: (1) mild, five cases; (2) moderate, eleven cases; (3) severe, three cases. The rapidity of response did not vary accurately with the original severity of the choreic movements; mild cases sometimes proved more resistant than severe ones. The criterion of cure or arrest taken by various authors is not always the same. To remove all ambiguity in the cases under discussion the attack was not registered as over until the condition had so far improved that an average medical man would have had difficulty in diagnosing the case as one of chorea at all. Spontaneous movements had ceased. Voluntary movements were of average accuracy, and the patient could sustain a steady hand-grip for a minute or more without fluctuation.

CASE HISTORY

One typical case (Case 12) will be quoted, and the rest will be summarized in a table.

A girl, aged 16, was admitted on October 28th, 1932, for chorea. First attack four years ago; tonsillectomy three years ago; second attack two years ago. Present attack began two days before admission. Movements were violent, and involved all parts of the body. Boards were fixed to the sides of the bed to prevent the patient from falling out. Voluntary movements could not be performed usefully. A slight systolic bruit could be heard at the apex, but there was no evidence of active endocarditis. Temperature almost normal. No joint pains.

October 26th: Onset of attack. October 28th: Calcium aspirin (Coplans) 15 grains t.d.s., given daily. November 7th: Movements almost disappeared; bed boards removed; could feed and dress herself with ease. November 11th: No movements discernible; impossible to demonstrate the case as one of chorea. Complete arrest was achieved after fourteen days of treatment and within sixteen days of the onset of a severe attack. The extreme limits recorded for spontaneous cure in such cases are thirty to 180 days, and the average is sixty-seven.

Table of Cases

Case	Age	Sex	Group	Attack	Maxi- mum Pyrexia	Heart	Joints	Daily Dose	Time Required for Arrest
1	7	F	Mild	1	99.2°	Normal	Normal	grains 30	days 12
2	12	F	Severe	1	98.8°	Apical systolic bruit	Normal	45	16
3	9	M	Moderate	1	99.8°	Normal	"	30	10
4	14	F	Mild	2	101.6°	Apical systolic bruit	Pains	60	19
5	11	M	"	2	98.6°	Normal	Normal	45	9
6	9	M	Moderate	1	102.6°	Endocarditis	"	30	46
7	13	M	"	1	99.4°	Normal	"	45	20
8	12	F	"	3	98.4°	"	"	45	8
9	8	M	"	1	99.0°	"	"	30	12
10	6	F	"	1	99.8°	Apical systolic bruit	"	25	14
11	10	F	Mild	1	101.4°	Normal	"	30	28
12	16	F	Severe	3	98.8°	"	Pains	45	14
13	12	F	Moderate	2	99.2°	"	Normal	45	21
14	9	M	"	1	101.2°	"	"	30	16
15	17	F	"	2	98.2°	"	Pains	60	15
16	11	M	Severe	1	99.6°	Apical systolic bruit	Normal	45	11
17	8	F	Moderate	1	102.0°	Normal	Pains	20	13
18	12	F	"	1	100.6°	"	"	45	24
19	9	F	Mild	1	99.4°	Endocarditis	Normal	30	7
						Apical systolic bruit	"		

The average time taken to control these patients was seventeen days, and the limits seven to forty-six days respectively; figures which compare very favourably indeed with the average expectation of thirty-five days for mild chorea cases and the sixty-seven days for severe ones referred to in the earlier part of this paper. The drug diminished the discomforts of the patients at all stages of the treatment, and did not produce any of that mental depression which accompanies the use of chlorotone and certain other hypnotics. There was no undue drowsiness or digestive derangement. There was no relapse or secondary exhaustion when the drug was finally withdrawn.

Conclusions

Calcium aspirin (Coplans)* affords a method of treating chorea without occasioning exhaustion, discomfort, or risk to the patient. It is less toxic^{14, 20} than acetyl-salicylic acid itself, and is free from the irritant action of the parent substance on the stomach and bladder. It is freely soluble, almost tasteless, and is rapidly absorbed. It has a triple action: (1) anti-rheumatic, (2) correction of calcium deficiency, (3) sedative to the brain.

The best results are secured when the patient is kept in bed during treatment and protected from undue emotional and mental stress.

 $(C_6H_5(OCOCH_3)CO_2)_2 \cdot CaH_2O + 1/3 CaCl_2$

The Health and Cleanliness Council (5, Tavistock Square, W.C.1) has issued a revised edition of its pamphlet first issued in 1926, incorporating suggestions for a local health and cleanliness campaign. Supplies are available for distribution free of charge, and applications for copies should be addressed to the secretary, Miss Norah March, B.Sc., at the address given above. The advisory board of the council consists of Dr. George F. Buchan (chairman), Dr. Sophia Friel, Miss J. Halford, Professor H. R. Kenwood, and Dr. Eric Pritchard.

THROMBOSIS OF THE PENIS AND URETHRAL HAEMORRHAGE*

BY

CLIFFORD MORSON, O.B.E., F.R.C.S.

PRESIDENT, SECTION OF UROLOGY, ROYAL SOCIETY OF MEDICINE

Thrombosis may occur either in the veins of the penis or in the corpora cavernosa. The latter consist of spaces which fill with arterial blood when the penis is in a state of erection. This is only a part of the physiological process leading to enlargement of the organ. The glans is the terminal portion of the corpus spongiosum, and also distends with blood in the presence of sexual excitement.

The causes of a persisting enlargement of the penis are either nervous or vascular, and each can be recognized by the shape of the organ. Priapism is due to a nervous lesion, and the appearance of the penis is similar to that seen in the physiological state. On the other hand, thrombosis of the corpora cavernosa leads to the formation of a hard and tense swelling of the whole organ, *except the glans*. If the clotting is more extensive in one corpus than the other deviation occurs, and the penis is bent to the side which is more thrombosed. There are three diseases which may lead to the clotting of the blood in the cavernous spaces. They are malignant disease of the left kidney, lymphatic leukaemia, and arteriosclerosis. Whichever the cause, the condition is fortunately rare.

The explanation of the reason why thrombosis of the corpora cavernosa occurs in carcinoma of the left kidney is purely anatomical. The spermatic vein on this side of the body enters the renal vein. If the latter becomes blocked with growth at the point of entry of this tributary, stagnation of the blood occurs in the penis and left testicle, so that not only does pseudopriapism occur, but there is a temporary swelling of the latter due to the block in the pampiniform plexus. These veins can be felt as a hard mass in the inguinal canal. No original observations can be made on penile thrombosis due to lymphatic leukaemia, for the writer has never seen a case. However, most textbooks describe it as a complication of this blood disease, and it must be accepted as a fact unless proved to the contrary.

With regard to arteriosclerosis as a causal agent, two cases of thrombosis of the penis have been investigated in which the local lesion has been proved to be due to arterial disease. A study of the literature reveals that a considerable number have been described in which the cause is stated to be unknown. More accurate observation would have cleared up the mystery. In view of the fact that the nipple of a female breast consists of erectile tissue it is probable that thrombosis has occurred in this organ also in relation to arterial disease, but such a case has yet to be recorded.

Thrombosis: Case Records

The details of the two cases of thrombosis of the penis are as follows:

The first case to be carefully investigated was that of a man, aged 35, who was admitted to Whips Cross Hospital with the whole of the penis, apart from the glans, swollen and hard. The enlargement extended back to the bulb. The history was that the swelling had been of gradual onset, a period of three days having elapsed before it reached its full size. During this time repeated coitus had failed to produce any change in the organ. On admission the patient was in considerable distress, and complained of difficulty in micturition. There was no pain. The medical officer,

* A communication read before the Dutch Urological Association at Amsterdam, April, 1934.

believing the condition to be due to a nervous lesion, tried the effect of spinal anaesthesia, with a negative result. Leukaemia was then excluded by an examination of the blood. The Wassermann reaction was negative. Marked thickening of all superficial arteries was noted. The systolic blood pressure was 145. The urine was normal. In three weeks the penis had resumed its natural size, and the patient was then discharged. It is now over twelve months since this patient was in hospital. Every effort has been made to trace him, but letters remain unanswered.

The second case is of a more recent date. The patient, aged 45, has an exactly similar history to that of the first case. Again the medical officer thought he was dealing with a nervous lesion, and injected stovaine into the theca, with an unsatisfactory result. The patient was obviously suffering from arteriosclerosis, the radial arteries being hard and tortuous. The Wassermann reaction was negative, as was also the examination of the blood for leukaemia. The systolic blood pressure was 130. Urine normal. The patient discharged himself from hospital one week after admission, with no change in the size of the penis. This was at the beginning of July, 1932. Three months later, in answer to a letter, he presented himself for examination. The history was that the penis had become normal in size three weeks to a month after the onset of the swelling. He stated that he was enjoying good health apart from occasional headaches. His systolic blood pressure was 140, ten points higher than in July, 1932. Definite thickening could be felt along each corpus cavernosum. The patient stated that he was impotent. Sexual desire was strong, but there was no response in the penis, evidence that the nervous mechanism controlling coitus was intact, but the vascular system defective.

Local treatment in these two cases consisted of the application of evaporating lotions to the perineum, but it should be remembered that absorption of the clot occurs irrespective of either surgical or medical interference. Some writers advocate incisions into the corpora cavernosa, which shows their lack of understanding of the pathology of the lesion.

The other type of thrombosis of the penis occurs in acute infective processes of the urethra, the best example of which is gonorrhoea. In this condition it is the superficial veins which tend to clot, leading to oedema of the prepuce and subcutaneous tissues. It is really a case of phlebitis in an unusual situation. Resolution occurs slowly, but no permanent ill effects follow this complication. Dr. J. L. Morton reports to the writer that he has had under his care a man with thrombosis of the dorsal vein who has suffered for many years from syphilitic arteriosclerosis.

The study of urethral haemorrhage introduces problems of great pathological interest. Bleeding may occur either at the beginning or the end of micturition. On the other hand, it may be entirely independent of the passage of urine, and, lastly, it will take place during coitus.

Haemorrhage

There is no need to discuss in detail the causes of urethral haemorrhage in association with micturition, for they are well recognized. Any acute urethritis—gonococcal, tuberculous, or that due to the *Bacillus coli*—by the severity of the inflammation, will give rise to the dripping of blood, either before or after micturition. Also tumours of the urethra, such as papilloma and carcinoma (both rare diseases in this situation) cause haemorrhage. Again, a stone impacted in any part of the urethral tract may cause bleeding. One case of haemorrhage immediately after micturition is worthy of record on account of failure to discover the cause.

The patient was a well-built lad of 16½ years, who complained of a pain at the end of the penis after micturition, followed by a profuse flow of blood from the urethra. Quite two tablespoonfuls of blood were seen to escape immediately after micturition had ceased. The cause of the bleeding remains a mystery, in spite of all the known methods of

investigation, such as cystoscopy, urethrography, urethroscopy, urine analysis, and examination of the blood. All proved negative to disease except the urethroscopy, which revealed what looked like a small ulcer on the ventral aspect of the mucous membrane of the bulbous urethra. Irrigation daily with a solution of one in 10,000 silver nitrate has failed to stop the bleeding, and one is forced to the conclusion that the condition is due to self-inflicted trauma.

The best-known examples of urethral haemorrhage independent of micturition are rupture of the tube, complete or incomplete, and damage to the mucous membrane due to instrumentation. It must not be forgotten that the passage of a bougie, catheter, or cystoscope, however gently handled, always causes bleeding. With the skilled urologist this is only detected by the microscope. Occasional spontaneous urethral haemorrhage will occur from the vessels which supply an adenomatous prostate. Oozing of blood may be continuous and of such severity as to cause clot retention. This complication is in no way caused by the act of micturition, but is probably initiated by straining at stool.

Lastly, we have to consider what may be termed urethral epistaxis in relation to coitus. It is only within the last few years that this phenomenon has been recognized as a manifestation of serious arterial disease. Previously it was labelled "malade imaginaire." Three cases have been carefully studied and kept under observation; one patient still being alive and the other two dead. Their notes are given in full in the presidential address to the Section of Urology, October, 1933, but it may be helpful to recapitulate some of the salient points in the clinical histories.

The first case was dismissed as an anxiety neurosis, and it was only when the patient, 35 years of age, brought his pyjamas stained with blood to the consulting room that it was realized a mistake in diagnosis had been made. It was then decided to examine carefully the vascular system. All the superficial arteries were clearly sclerotic and the systolic blood pressure raised. The urine showed evidence of changes in the kidneys, hyaline and granular casts being present. The loss of blood during coitus continued until the patient became seriously ill with chronic nephritis, from which he eventually died.

Thus the sequence of events in the medical history is that this young man suffered from arterial disease from an early age, that the strain of coitus on occasions caused rupture of a blood vessel of the urethral mucous membrane, and that the uraemia from which he died was the result of arteriosclerosis.

The second case was that of the editor of a well-known paper, a man aged 45, who had a severe haemorrhage into the prepuce during coitus. He also gave a history of urethral haemorrhage. It was already known that for some years he had suffered from arterial disease and hyperlipis. A few months after being treated for the haematoma of the prepuce he died of cerebral haemorrhage.

The third patient is still alive, having been under medical observation for the past two years. He also has had urethral haemorrhage during coitus, due to arteriosclerosis and high blood pressure. Chronic nephritis is present, but, in spite of his disease and the fact that he is 64 years of age, he continues to work, and makes few complaints about his health.

Conclusion

These cases demonstrate very clearly how important it is that the urologist shall be just as much a student of medicine as he is of surgery. In fact, if he is satisfied to confine his interests to instrumental and operative technique, he will gradually disappear as an expert in diseases of the genito-urinary tract. The urologist of the future must be a man competent to diagnose accurately all constitutional diseases which first manifest themselves by purely urinary symptoms.

AUG. 11, 1934]

POSTURAL DRAINAGE OF THE LUNGS*

BY

H. P. NELSON, M.A., M.D., F.R.C.S.

CHIEF ASSISTANT (SURGICAL), ST. BARTHOLOMEW'S HOSPITAL; ASSISTANT
SURGEON, BROMPTON HOSPITAL FOR DISEASES OF THE CHEST;
THORACIC SURGEON TO THE LONDON COUNTY COUNCIL

The assumption of the upright posture has necessitated readjustments which affect every anatomical structure in the body and modify all the vital physiological processes. As a secondary outcome of this posture many spaces of the body are so situated that gravity causes their contents to accumulate farthest from their natural outlet.

In the upright position the upper respiratory tract is situated above the lower respiratory tract and can drain freely into it, and even in the supine position lipiodol, if it is introduced into the nasopharynx while the patient is heavily asleep, will enter the bronchi. This fact explains the close relation between nasal and bronchial infection. Through force of habit the majority of people sleep with two pillows, and patients with respiratory infections are provided with twice or three times this number, so adopting a position in which gravity drainage is impossible.

The natural methods of emptying the tracheo-bronchial tree of accumulated secretion are on the whole extremely inefficient. 'Ciliary action only removes minute particulate matter such as dust or bacteria, and is of no value when there is much secretion.' Although a peristaltoid movement of the bronchi has been described by one or two observers, its existence is extremely doubtful. Coughing is, of course, the physiological method by means of which secretions in excess are expelled from the tracheo-bronchial tree. The cough reflex functions very rapidly distal to this, and a high degree of tolerance to the presence of pus can be obtained. Reinberg¹ observed that when he ran opaque material in through a bronchial fistula no cough was produced until one of the primary bronchi was filled, and I have been surprised when bronchoscopic long-standing cases of bronchiectasis to see the whole of the lower lobe bronchus completely filled with pus without the patient having any desire to cough. The expulsive force of the cough is considerably hampered by the contraction of the lumen and shortening of the bronchi which occur during expiration and, even more so, on coughing. In children the lumen of a bronchus appears through the bronchoscope to close completely on coughing. The cough also scatters pus throughout both lungs, and the deep inspiration which precedes the cough drives it distally. In addition, coughing is a severe drain on the strength of a debilitated patient.

Intermittent Postural Drainage

The inadequacy of the physiological methods of cleansing the lung when secretion is considerable has led me to investigate the assistance which might be obtained from posture—namely, of using gravity to empty the lungs. It is clear that postural treatment is only likely to be successful and can only be properly applied when a precise anatomical knowledge of the position and direction of each broncho-pulmonic unit is obtained. What is usually implied by postural drainage, however, is the tilting of the patient into an almost vertical position with the head downwards for a few minutes several times a day. This should be called intermittent inverted postural drainage. It is effective in clearing the trachea and primary bronchi of accumulated secretions, but has very little effect on the secondary or tertiary bronchi, which

are the ones affected in bronchiectasis. In a case of bronchiectasis, if bronchoscopy is performed immediately after this type of posture quantities of pus will still be found in the lower bronchi, and lipiodol will often remain there for a week or more, in spite of frequent inversion of the patient. In the case of lung abscess, the communication with the bronchus is rarely large enough for the free escape of pus, and this brief inverted posture only gets rid of that which has overflowed into the main bronchi. It is obvious that this posture can be of no assistance in draining those bronchi which do not run upwards towards the mouth. Again, the sudden change into a head-downwards position is distressing to adults, and with acutely ill patients is usually impracticable.

Continuous Postural Drainage

The object of this paper is to describe a technique for continuous postural drainage as opposed to intermittent postural drainage. This is no new idea,² and was described by William Ewart³ in 1901, and later referred to by him as the "empty bronchus treatment by posture in the bronchiectasis of children." By this means the area of suppuration, whether it is bronchus or pulmonary cavity, is subject to an almost continuous drainage, which permits the pus to find its way out and prevents its reaccumulation. In continuous drainage the posture is maintained not for minutes but for hours at a time, and it must therefore be more or less comfortable, so that the patient can even sleep in the correct position. The posture must be such that the bronchus leading from the affected area is dependent, and the bifurcation of the trachea is the centre to which drainage is directed, and not the mouth. This can be expressed diagrammatically by imagining the chest to be a sphere, the centre of which is the bifurcation of the trachea and the affected area a cone in this sphere; then the correct posture is obtained by placing the sphere so that the base of the cone is uppermost. By means of a gentle cough pus can easily be expelled from the trachea, and if it has accumulated there while the patient is asleep leaning over the side of the bed on waking will assist its expulsion.

Anatomy of Postural Drainage

The postures which are here suggested for internal bronchial drainage are based on investigations which I have carried out on the bronchi and their distribution in the lung. This anatomical work will be published elsewhere, and only the briefest outline is given in this paper. The three figures (Figs. 2, 3, and 4) are tracings from lipiodol fillings of the bronchi; each comes from a different case, and they are chosen because of their close approximation to the average anatomical arrangement. It is customary to describe the lungs as having three lobes on the right side and two on the left, but despite this fact the internal structural relations are the same on the two sides and are symmetrical. It is therefore permissible to describe the two lungs in terms of four principal areas—namely, upper, middle (ventral), dorsal, and lower, which are set out in Fig. 1.

Upper Lobe, Right Lung

The bronchus to the upper lobe of the right lung arises from the lateral wall of the main bronchus, opposite to the bifurcation of the trachea (see Fig. 2). It runs horizontally outwards, lying in the same plane as the trachea and primary bronchi, and cannot, therefore, be identified in Fig. 3. After a course of approximately 1 cm. it divides into three branches:

1. *Apical*.—Running upwards, outwards, and slightly backwards to supply the true apex above the level of the clavicle and the posterior surface of the lobe (see Figs. 2 and 3).

* Work done under the Ernest Hart Memorial Scholarship of the British Medical Association, 1932-3.

POSTURAL DRAINAGE OF THE LUNGS.

[THE BRITISH
MEDICAL JOURNAL]

2. *Axillary*.—Continuing the direction of the parent bronchus outwards to supply the axillary surface of the upper lobe. This can be seen in Fig. 2, but in Fig. 3 all except one small branch is in cross section.

3. *Pectoral*.—Running horizontally forwards to supply that portion of the upper lobe lying underneath the pectoral muscles between the clavicle and the fourth rib in front. In Fig. 2 this is in transverse section, but can be seen in Fig. 3.

Upper Lobe, Left Lung

The bronchus to the upper lobe of the left lung corresponds on the left side to a composition of the upper and middle bronchi of the right side. Its origin is from the antero-lateral surface of the left main bronchus at its termination, and after a course of less than 1 cm. it divides into two component parts—namely, left upper bronchus and left ventral (middle) bronchus (see Fig. 1).

On account of its low origin, the left upper bronchus and its branches all tend to have an upward direction. The

apical (above clavicle), and posterior portions of the upper lobe. These bronchi can be seen in Figs. 2 and 4.

Middle Lobes, Left and Right

The bronchus to the right middle lobe arises from the anterior surface of the right main bronchus, about 2 cm.

FIG. 1.—Diagram showing the four principal areas in each lung.

FIG. 3.—Lateral view, showing the distribution of the bronchi on the right side.

FIG. 2.—Antero-posterior view showing the distribution of the bronchi. For descriptive details of anatomical figures, see text.

bronchus itself is not more than about 5 mm. in length, and runs upwards and slightly outwards (see Figs. 2 and 4). It then divides into two branches:

1. *Pectoral*.—Running upwards, outwards, and forwards to supply the pectoral portion of the left upper lobe between the level of the clavicle and the fourth costal cartilage.
2. *Axillary-apical*.—Running upwards and backwards, and, as its name implies, supplying branches to the axillary,

FIG. 4.—Lateral view, showing the distribution of the bronchi on the left side.

below the bronchus to the upper lobe, and runs forwards, outwards, and downwards (see Figs. 2 and 3). The middle "lobe" of the left lung is that portion situated below the plane of the fourth costal cartilage, and occasionally there is an actual fissure separating it from the rest of the upper lobe (see Fig. 1). The bronchus to this area arises, as I have explained above, from the bronchus to the left upper lobe, and runs outwards, forwards, and downwards (see Figs. 2 and 4).

The Dorsal Area

By the dorsal area is meant the upper part of the lower lobe. Although usually incorporated in the lower lobe, this area is occasionally separated from the rest of the lobe by a fissure. Anatomically, and clinically it acts independently of the rest of the lower lobe, and is entitled, as I have said elsewhere,¹⁰ to be called the dorsal area, and the bronchus that supplies it the dorsal bronchus (see Fig. 1).

The right dorsal bronchus arises from the posterior surface of the right main bronchus, almost opposite the origin of the right middle bronchus (see Fig. 3). It will thus be seen that the right main bronchus terminates by dividing into three branches—middle, dorsal, and lower. The dorsal runs a short course horizontally backwards, and then divides into branches which supply the upper portion of the right lower lobe. The extent of the area supplied is variable, and may be a quarter of the whole lobe.

The left dorsal bronchus springs from the posterior surface of the left lower bronchus practically at its commencement, and has a direction and distribution like its corresponding member on the other side. In Fig. 2 the origin of this bronchus is seen on both sides as a circle, with its tertiary branches just visible, but in Figs. 3 and 4 they are shown clearly.

Lower Lobes, Right and Left Lungs

On both sides the bronchus to the lower lobe gives off at its commencement the dorsal bronchus, as I have mentioned above; it then continues for about 2 cm. and terminates by dividing into anterior-basic and posterior-basic bronchi; the latter then gives off a large branch from its lateral surface—the axillary-basic bronchus. On the right side there is a separate cardiac branch arising from the medial wall of the lower lobe bronchus; it runs downwards and slightly inwards and backwards, to supply a small area lying just below the root of the lung. On account of its small size this bronchus will not be considered again.

The anterior-basic bronchus springs from the antero-medial surface of the lower lobe bronchus at its termination, and then runs downwards and outwards and forwards to supply the cardiac surface and the antero-inferior angle of the lower lobe (see Figs. 2, 3, and 4).

The axillary-basic bronchus comes from the lateral surface of the posterior-basic bronchus at its origin, and runs downwards and outwards to supply the axillary surface of the lower lobe (see Figs. 2 and 3), but in Fig. 4 this bronchus can only be seen at its commencement.

The posterior-basic bronchus continues the line of the main bronchus and lower lobe bronchus downwards, backwards, and slightly outwards (see Figs. 2, 3, and 4). It is the largest of the four branches, and supplies the posterior surface of the lower lobe below the dorsal area, the so-called "base" of the lung.

Localization of Lesions

The correct posture cannot be determined until we know the exact position of the lesion. For this we depend on physical signs and x-ray examination. Physical signs, when present, are of the greatest value in the localization of a lesion, but when they are only vague or absent altogether we must fall back on the x-ray.

In bronchiectasis the diagnosis and localization of the lesion cannot be made by physical signs alone. For the latter x-ray examination is by far the most valuable method. It is necessary to have either stereoscopic films or two views of the chest taken at right angles to each other—namely, antero-posterior and lateral—before it is possible to state the exact position of a lesion. It is customary to centre the x-ray tube at the level of the manubrio-sternal junction, so that in the film the clavicles and posterior ends of the fourth ribs are superimposed. In addition, the tube should be at least four feet distant from the film. The description that appears in the next section is based on films taken under these conditions. For the purpose of posture the antero-posterior film is divided into three zones—upper, middle, and lower—by two horizontal lines, the first passing through the first costal cartilage and the second through

the fourth costal cartilage (see Fig. 5, A): the significance of this division will be discussed in the next section.

In a normal lateral film the following features can be observed. Anteriorly is the sternum, posteriorly the vertebrae, forming a concave line, and, below, the diaphragm (see Fig. 5, B). There are two opaque areas: one is caused by the shoulder girdle, and is at the apex of the chest posteriorly (it varies with the position and size of the limb); while the other is caused by the heart, and lies anteriorly just above the diaphragm. There are also two translucent areas: one above the heart and anteriorly and the other between the heart and the vertebrae. The trachea is seen as a clear band running downwards and backwards through the upper part of the lung field, one-third of the distance from the vertebral bodies to the sternum. This clear area terminates at about the level of the sixth rib, and on the right side there is at this point a small oval translucent area, which is at the origin of the middle and dorsal bronchi and in the plane of the oblique fissure. If the axis of the trachea is continued downwards and backwards as a straight line it reaches the diaphragm just anterior to the vertebrae: this line can conveniently be called the tracheal axis. The position of a lesion in relation to this axis is described as anterior (pectoral), posterior (dorsal), or, when it is situated on the line, as lateral (axillary).

FIG. 5.—Showing the antero-posterior and lateral views of the normal chest.

The axillary border of the scapula may be seen somewhere between the trachea and the posterior border of the vertebrae.

Bronchiectasis requires lipiodol for its localization, and it is wisest not to fill both sides at the same time because of the confusion when they are superimposed in the lateral view. When filling the lower bronchi the patient should, in addition to the usual reclining position, be inclined forwards and then laterally for part of the time, so that the oil enters the anterior and laterally running bronchi: frequently the lateral film shows that only the posterior-basic bronchus has been filled. Even in the best lateral films it is sometimes difficult to find an opacity that is clearly visible in the antero-posterior view, owing to its being superimposed on the opacity of the heart or vertebrae. For this reason the ideal method of localization is by stereoscopic films, and they have another advantage that in the case of lipiodol both sides may be filled at the same time. It is unfortunate, however, that stereoscopic films are not in general use in this country, and for this reason I have confined the discussion to the antero-posterior and lateral films.

The Postures

The posture which a patient should adopt will depend on the position of the pulmonary lesion. In the antero-posterior x-ray film the lesion may be in the upper, middle, or lower zone. The upper zone is in reality the apex of a cone, and as it is supplied by one bronchus

POSTURAL DRAINAGE OF THE LUNGS

[THE BRITISH
MEDICAL JOURNAL]

this area does not require any subdivision. The middle and lower zones, on the other hand, are each subdivided according to the lateral x-ray film into three areas— anterior, lateral, and posterior. The lung fields are thus divided into seven areas on each side of the chest, and for each of these areas there is a different posture. For purposes of postural drainage the two sides of the chest may be considered as symmetrical, with one exception, which will be mentioned later.

The Upper Zone

In this zone the main extent of the opacity is situated above the level of the first costal cartilage: it always extends up to the apex, and may extend downwards towards the root of the lung. In the lateral film the opacity is at the apex posteriorly, and cannot be distinctly seen owing to the opacity caused by the shoulder girdle. This area is supplied on the right side by the apical bronchus, and on the left side by the apical branch of the axillary-apical bronchus. On both sides the surface of the lung corresponding to this bronchus (later referred to as the surface distribution) lies mainly behind, above the spine of the scapula but extending forwards as far as the clavicle; physical signs may be found over this area. The posture for a lesion in this position is sitting upright—namely, the Fowler position.

The Middle Zone

This zone extends from the first to the fourth costal cartilage. According to the position of the lesion in the lateral film this zone is subdivided into three areas.

1. *Pectoral*.—In the antero-posterior film the opacity is situated between the second and fourth ribs in front, in the centre of the lung field, while in the lateral film it lies anterior to the tracheal axis in that normally clear area between the trachea and sternum. This area is supplied on both sides by the pectoral bronchus, which has a surface distribution in front of the chest between the clavicle and the fourth rib: physical signs may be found over this area. The posture for a lesion in this region is lying flat in bed on the back—namely, supine.

2. *Axillary*.—In the antero-posterior film the opacity is situated between the second and third ribs in front in the outer half of the lung field, and extending to the periphery. In the lateral film the opacity overlies the trachea, which cannot therefore be distinguished, and may also extend posterior to this axis. On the right side this area is supplied by the axillary bronchus, and on the left by the axillary branch of the axillary-apical bronchus. On both sides this bronchus has a surface distribution in the axilla above the line of the sixth rib: physical signs may be found over this area. The posture for a lesion in this region varies slightly on the two sides. When it is on the right the patient should be lying flat and rotated on to the left side—namely, the lateral position; but when it is on the left the patient should be sitting up at an angle of approximately 45 degrees and rotated on to the right side.

3. *Dorsal*.—In the antero-posterior film the opacity is situated in the inner half of the lung field, and appears to be in the hilum of the lung. In fact, an abscess in this situation has frequently been called a hilar abscess, but when a lateral film is taken it will be seen to lie posterior to the tracheal axis, overlying the body of the seventh, eighth, or ninth

vertebra. On both sides this area is supplied by the dorsal bronchus, which has a surface distribution posteriorly in the region of the inferior angle of the scapula, and it is here that physical signs may be found. The posture for a lesion in this region is lying flat and turned over on to the face—namely, the prone position—and when the lesion is on the right side the patient's head is turned to the right, and vice versa.

The Lower Zone

This zone extends from the level of the fourth costal cartilage down to the diaphragm. Like the middle zone, it may be subdivided into three areas:

1. *Middle and Anterior-basic*.—In the antero-posterior film the opacity is situated between the fourth rib in front and the upper surface of the diaphragm when it is in the middle lobe, or laterally and in the costo-phrenic angle when it is in the anterior-basic bronchus. In the lateral film the opacity lies anterior to the tracheal axis and is superimposed upon that of the heart, and in this view it is practically impossible to distinguish a middle from an anterior-basic lesion. This area is supplied by two bronchi: (a) the middle lobe bronchus on the right and the ventral on the left, which have a surface distribution in front of the chest below the fourth costal

cartilage, where physical signs may be found; (b) the anterior-basic bronchus, which has only a small distribution on the costal surface of the lower lobe in the anterior axillary line about the level of the sixth rib, where physical signs may be found. The posture for a lesion in the middle or anterior-basic regions is lying flat on the back with the foot of the bed raised about twelve inches.

2. *Axillary-basic*.—In the antero-posterior film the opacity is situated below the level of the fourth costal cartilage in the outer part of the lung field. In the lateral film it lies in the shadow of the heart and the anterior surface of the bodies of the vertebrae. On both sides this area is supplied by the axillary-basic bronchus, which has a surface distribution on the lateral surface of the chest wall below the sixth rib. The posture for a lesion in this position is lying on the opposite side in the lateral position, as for an axillary lesion, but with the foot of the bed raised about twelve inches.

3. *Posterior-basic*.—In the antero-posterior film the opacity is situated in the lower zone, and extends down below the level of the diaphragm, and on the left side it may be obscured by the shadow of the heart. In the lateral film the opacity lies mainly behind the tracheal axis, over the bodies of the lower thoracic vertebrae. This area is supplied by the posterior-basic bronchus, which has a surface distribution behind over the so-called "base of the lung." The posture for a lesion in this region is lying prone with the foot of the bed raised about twelve inches. It is for lesions in this position that the postural drainage bed, described below, has been designed (see Fig. 6).

FIG. 6.—Showing patient on author's new postural drainage bed.

The Application of Postural Drainage

In spite of the statements made by some authorities that patients themselves usually discover the position in which they drain most satisfactorily, I find, generally, that they are sitting up in bed and in a position in which

they are inclined to cough the least. By examination of the patient and the x-ray film the best posture is determined, and the patient is instructed that he should lie in such-and-such a way. The reply "But that is the one position in which I cannot lie because it makes me cough all the time" confirms the decision. With unwilling patients I usually suggest that to begin with they should adopt the position for ten minutes three times a day before meals, and then I find that this period can gradually be increased, until in the end the posture is maintained for at least three periods of two hours during the day and for the greater part of the night. In patients who are acutely ill the sudden change from the sitting-up position may be extremely embarrassing, in which case they must be gradually lowered during the course of several days. There is usually an increase in the quantity of sputum, followed by a gradual diminution.

In the foregoing section lesions confined to definite localized areas of the lung have been described, but frequently two or more contiguous areas are involved at the same time, as, for example, all the tertiary branches of the lower bronchus or the apical and axillary branches of the upper lobe bronchus. In these circumstances one principal posture must be adopted which is more or less common to them all—namely, the horizontal for a middle zone lesion or with the foot of the bed raised for a lower zone lesion. Again, the lateral position, being half-way between prone and supine, is found to be the most useful, with occasional changes into the prone and supine. I have noticed the frequent combination of bronchiectasis in the posterior-basilar and middle or ventral bronchi; in these cases the patient is placed on the postural drainage bed or with the foot of the bed raised, and spends part of the postural time prone and part supine.

A Postural Drainage Bed*

In this bed (Fig. 6) the mattress frame is hinged across the middle, and on winding a handle at the foot of the bed the centre gradually rises. Before starting to "wind up," the patient's pillows are removed, and he lies in the prone position with the anterior iliac spines opposite the hinge; on winding up, the head, thorax, and abdomen hang down on one side and are counterbalanced by the lower limbs on the other. The maximum inclination that can be obtained in this bed is 45 degrees, but this is too steep for most cases, and especially for adults, who should be placed between 20 and 30 degrees. At the lower end of the bed the legs have adjustable inner tubes, so that the foot of the bed can be raised eighteen inches. The same bed can be used flat for the lateral and supine positions.

Summary

1. The advantages of a continuous posture are compared with the disadvantages of an intermittent posture.
2. The drainage should be towards the bifurcation of the trachea.
3. A brief account of the anatomy and distribution of the larger bronchi is given.
4. In the localization of pulmonary lesions the lateral x-ray film is as important as the antero-posterior one.
5. When lesions are considered according to their position in the antero-posterior film, those in the upper zone are treated in the sitting position, those in the middle zone by lying flat, and those in the lower zone with the foot of the bed raised.
6. When lesions are considered according to their position in the lateral film, those occurring anterior to the tracheal axis are treated in the supine position, those on the tracheal axis in the lateral position, and those posterior to it in the prone position.

* This bed has been made for me by Hoskins and Sewell Ltd., of Bordesley, Birmingham.

7. Some practical points in the application of postural drainage are mentioned.

8. A new postural drainage bed is described for the treatment of basal lesions in the prone position.

A full report of cases treated by these postural methods will be published elsewhere.

Clinical Memoranda

A CASE SHOWING CULLEN'S SIGN

The rarity of Cullen's sign of extrauterine gestation, together with certain unusual features of the case, warrant record. The patient herself noted the condition, and the diagnosis was made originally on the presence of this sign.

CLINICAL HISTORY

C. S., aged 34, after seven years of childless marriage, had a normal menstrual period from August 5th to 9th, 1933. Six weeks later she consulted her doctor on account of vague lower abdominal pain of fourteen days' duration, but did not mention that suppression of the expected menstrual period had occurred. Abdominal examination did not suggest anything abnormal, and she was given mist. alba as a placebo. On the afternoon of September 26th, 1933, seven weeks after the last period, whilst taking tea with a friend, she experienced some accession of pain and examined her own abdomen. She "did not like the look" of some marks there, and sent for her doctor, who, on seeing the marks, made a diagnosis of tubal gestation. I saw the patient in consultation with Dr. Cathie of Felling-on-Tyne about an hour later. She was a spare woman with a well-marked acne rosacea; temperature 98.4°; pulse 80. Since being seen by Dr. Cathie she had commenced to pass a certain amount of dark blood per vaginam. She complained of pain, with periodic exacerbations in the hypogastric region, and the bladder was distended to the size of a five months pregnancy. On relief of this pain by catheterization she described her pain as being situated over the left iliac fossa. One inch below and to the left of the umbilicus was a purple, almost black, clearly cut mark 3/4 in. by 1/4 in. shaped like a comma. Below it, about the junction of the upper third and lower two-thirds of the distance from the umbilicus to the pubes, was a "bruise," bluish in colour, about 1 in. in diameter, whilst abutting on the inguinal fold was a reddish-purple mark like a fresh bruise, shaped roughly like the ace of clubs, about 2 1/2 in. in diameter. Neither of the two lower marks was so clearly cut or so intense in coloration as the upper mark. The whole was within the triangle formed by the midline and a line drawn to the umbilicus from the middle of the left inguinal ligament. On bimanual examination a soft mass the size of a hen's egg was evident in the left tubal region. There was not any evident dullness in the flanks.

OPERATION

She was admitted to the Royal Victoria Infirmary, Newcastle-upon-Tyne, where I opened the abdomen and removed the distal

half of the left Fallopian tube, which contained an ampullary pregnancy surrounded by a little blood clot. The tube was not ruptured, but a little dark blood was oozing from the abdominal ostium. In the peritoneal cavity there were not more than 3 or 4 oz. of dark fluid blood. Inspection of the parietal peritoneum did not show anything abnormal in the region of the subcutaneous stains, whilst incision into the subcutaneous fatty tissue proved the stains to be true ecchymoses. The right tube was sealed at its abdominal ostium and bound down by old adhesions in the pouch of Douglas. The patient made an uneventful recovery and left hospital ten days later. The ecchymoses had by then faded considerably and, indeed, progressed as any bruise does.

COMMENTARY

The sign was first described by Cullen¹ in 1818, and since then has been noted by several American and Continental surgeons, but I have not been able to trace a record of a case in the British literature. Cullen's case is described as having "the umbilical region bluish black." There were $1\frac{1}{2}$ quarts of blood in the peritoneal cavity. It is not stated whether the coloration was a true ecchymosis or mere staining by blood pigment, nor whether it was limited to the side on which the pregnancy had occurred, as in the above case. Schumann² showed that the sign was not pathognomonic of extrauterine gestation, for he noted bluish discoloration about the umbilicus in a case with a highly suggestive symptom-complex which at operation proved to have a normal intrauterine pregnancy and bilateral acute purulent salpingitis. Cope³ mentions "bluish discoloration in the region of the navel" as an inconstant sign of extrauterine gestation.

It is an interesting speculation as to how the blood reaches the subcutaneous tissues. In the present reported case I forecast that there would be an intraligamentary rupture of the tube with a broad ligament haematoma from which blood had tracked up extraperitoneally as far as the umbilicus, possibly following the obliterated hypogastric artery by which the lateral spread of the discoloration was limited. There was no evidence of this at operation, nor was there any tubal rupture. The absence of any subperitoneal effusion of blood also eliminated any possibility of spread by following the round ligament to the subcutaneous tissues. If it were a matter of lymphatic absorption from the peritoneal cavity one would expect the staining to appear first in the flanks and to show as a gradually deepening diffuse blood pigmentation rather than clearly marked ecchymoses. In addition, one would expect Cullen's sign to appear more frequently in cases with gross haemoperitoneum. In forty-seven operations for ruptured tubal gestation this is the only case in which this sign has been seen.

From the history and appearances in this case one feels that one must postulate a breach of continuity of the parietal peritoneal endothelium at the umbilicus through which blood escaped into the subcutaneous tissue. The umbilical scar is the point at which such a breach is most likely to occur, and the infrequency of peri-umbilical ecchymosis in tubal gestation suggests that it is associated with some unusual anatomical feature.

Reviews

INFANT FEEDING AND MANAGEMENT

Dr. H. P. WRIGHT of Montreal has written a new book entitled *Essentials of Infant Feeding and Paediatric Practice*,¹ and in some two hundred pages he manages to include a great deal of information. The first section includes chapters on growth and physiology, leading on, after a discussion of the available milks and foods, to chapters on breast-feeding and artificial feeding in the normal infant. The second section discusses the principal nutritional disorders of infancy and early childhood, while the concluding section deals usefully with various subjects, such as therapeutic procedures, preventive measures, rules for controlling the communicable diseases, etc. Throughout the book the author draws on his wide personal experience, but he has not hesitated to make full use of the experience of others without burdening the book with too many references. For example, a chapter on anhydraemia, acidosis, and alkalosis interprets modern biochemical findings for the practising physician. This is an eminently readable and balanced production, to which the publishers have contributed their share in the clear print and stout binding for which the Oxford Medical Publications are well known.

In *Mothercraft*² Miss M. TRUBY KING has performed a modest task in an adequate manner in presenting her father's system of infant care and management "to meet the need of an inexpensive, up-to-date Truby King handbook for mothers and nurses." Such a need is perhaps not so obvious in this country as in the place of publication, but the book can be welcomed none the less as a careful exposition of these methods and principles, which have brought peace and happiness into many an agitated household. It is perhaps a little unfair to attack certain portions of the Truby King doctrine as set out in this book, for obviously the author has merely transcribed what others had previously taught. Nevertheless it is high time the method of over-diluting cow's milk for infants past the first few months of life was justified more scientifically than by the sweeping statement (p. 118): "The fatal objection to using whole cow's milk for babies . . . is the fact that the great excess of protein overtaxes both the digestive organs and the kidneys." The degree of dilution of cow's milk advised for the 6-months-old baby, for example, in order to reduce the hypothetical danger of too much protein, carries with it the real danger of reducing seriously the amount of vitamins and minerals present in the milk, and promoting the occurrence of nutritional disturbances such as anaemia. The wholesale condemnation of mackintosh drawers is also unwise. Properly used, these constitute a great boon to mother and baby, and there is no evidence that they are "most injurious" (p. 37) to the baby's general health.

The fourth edition of *A Practical Guide to Child Hygiene*³ was prepared by the late Dr. E. L. DE CHAZAL just before he died, and his collaborator, Dr. F. A. ROUGET, has been responsible for the final stages. Written essentially for the nurses, midwives, and mothers of Mauritius, this handbook contains a great deal of valuable information, and covers a very wide field.

A TEXTBOOK OF GYNAECOLOGY

A large number of readers will welcome the third edition of Dr. JAMES YOUNG'S *Text-Book of Gynaecology*.⁴ The format is a distinct improvement on that of its predecessors, while every chapter has been revised and several new ones incorporated. The main features of this work are a succinct but pleasant style, and an almost uncanny faculty for excluding that which it is unnecessary for a student to know. The modern views on the physiology of sex are epitomized without making extravagant implications with regard to gynaecological practice. We could have wished that a caveat against the indiscriminate use of endocrine preparations could have been included. Some gynaecologists will disagree with the author when he states that an infected cervix is a common cause of pain in women, while others will not accept his views on the pathology of chronic metritis and chronic endometritis. No mention is made of the frequency with which the rectum is involved in gonorrhoeal vulvo-vaginitis in young girls or of the fact that secretion of "milk" in the breasts is not uncommonly associated with uterine fibromyomata, while we do not believe it is necessary for women wearing a vulcanite pessary to douche themselves even three times a week. These minor criticisms merely emphasize the excellent qualities of the book and the sound judgement of the author. We have read it through with pleasure, and know of no more readable and valuable book on gynaecology for students. The third is in all respects an improvement on the well-known and proved previous editions.

HOUSING IN LONDON

In the volume on *Housing and Slum Clearance in London*,⁵ by HUGH QUIGLEY and ISMAY GOLDIE, a very important part is played by its illustrations. They are thirty-one in number, and show in an admirable way—in many respects better than any letterpress could do—the excellent achievements of a few recent housing schemes within the county of London, and the fact that they do not compare at all unfavourably with the justifiably vaunted successes of some such schemes in Germany, Austria, and Holland. Thus:

"The new estates built by the London County Council, above all in Kennington and Stamford Hill, the Cumberland Market buildings of the Commissioners of Crown Lands, the Duchy of Cornwall scheme in Kennington, and the Somers Town buildings of the St. Pancras House Improvement Society, must be included among the most remarkable and aesthetically satisfactory achievements of our time, and they definitely surpass the most expensive block of flats built in the West End of London."

Yet, in spite of this high praise, which it will be seen includes the London County Council, the authors conclude that:

"As far as London is concerned it may be necessary to remove housing at once from the range of control of the local authorities and of the London County Council, since the history of their activities is not such as to justify one in the belief that housing on an adequate scale will be properly handled and solved within an appreciable time by existing bodies."

This appears contradictory; and, indeed, the suggestion for a Ministry of Housing and of a National Building Board, with very wide powers and financial assistance, which is one of the main theses of the book, is not

⁴ *A Text-Book of Gynaecology. For Students and Practitioners.* By James Young, D.S.O., M.D., F.R.C.S.Ed., F.C.O.G. Third edition. London: A. and C. Black, Ltd. 1933. (Pp. 411; 220 figures. 16s.)

⁵ *Housing and Slum Clearance in London.* By Hugh Quigley and Ismay Goldie. London: Methuen and Co., Ltd. 1934. (Pp. 227. 7s. 6d. net.)

impressed upon the reader in any very clear and consistent fashion. For all that, however, it may be justified. The authors review in an effective way the history of housing; the position that the problem has occupied in the modern State; the way in which it has been dealt with by local authorities, by housing trusts, and by private enterprise; and the present campaign for slum clearance. They realize the importance of the uneconomic tenant, and emphasize the fact that the difficulties of housing increase with the size of the town—not merely proportionately, but almost in geometrical progression—and that this makes the London situation unique in this country. Evidently it can be solved in this case only by tenements, and the necessity for considering, understanding, and deliberately planning the most suitable conditions for these is of urgent importance in order to avoid the overcrowded buildings with a patch of asphalted ground which have hitherto represented the common idea of this type of scheme. Like most who write on this present situation, the authors conclude that

"the housing of the poor must not—cannot—depend on slum clearance; it is too slow and not sufficiently comprehensive. New housing by other means than private enterprise must be begun, now, while cheap money, cheap material, and idle labour are procurable."

LIFE AND SOUL

Several highly original and suggestive ideas in the domain both of physiology and of philosophy will be found in the volume entitled *Life and Soul*,⁶ by Dr. MAX LOEWENTHAL of Liverpool. The author is known for his research work in molecular physics and for his collaboration with Sir Victor Horsley in the investigation of the functions of the cerebellum. In an introduction to the first part of the present book Professor J. S. Macdonald writes:

"I know no better description of the general characteristics of living matter than the one contained in the pages of this book, and none so vivid. . . . Here the smooth surface of contemporary knowledge is attacked, and then with great sincerity and patience every facet is handled till the author's picture emerges complete, original, courageous, and in every detail open to examination. Nothing is proven, but everything is explained in a closely reasoned way and with transparent honesty."

As a professor of physiology Dr. Macdonald applies these words to the physiological part of the book only; but, as quoted above, there is no reason why they should not be used with reference to the whole. Throughout, the volume is characterized by obvious sincerity of conviction, by logical method, and by unusual clarity of thought and expression. The author sets out to seek, and claims to have found, a unifying theory—a characteristic feature common to all living beings and never met with in inanimate bodies—which will have the effect of converting physiology from the mere exact descriptive science which it is at present into a true interpretative science.

"As long as physiology does not claim to be more than applied physics and applied chemistry no theories are needed beyond those employed by these sciences. But if it has not resigned all hope of penetrating into the stronghold of life, which has been vainly besieged by the experimentalist for many years, a change of strategy must take place. . . . What is wanted is a science of 'biotics,' a science which accounts for all phenomena unexplainable by physics and chemistry."

Such a unifying theory or characteristic feature is declared to be that the unit of living matter possesses not a multimolecular structure such as that of ordinary

⁶ *Life and Soul. Outlines of a Future Theoretical Physiology and of a Critical Philosophy.* By Max Loewenthal. With foreword by Professor J. S. Macdonald, F.R.S. London: George Allen and Unwin, Ltd. 1934. (Pp. 291; 15 figures. 8s. 6d. net.)

ponderable substance, but a unimolecular, though, of course, polyatomic structure. This hypothesis is effectively developed and expounded in the first part of the book and is, in the second part, applied to the physiological processes which take place in the nervous system—central, peripheral, and terminal—of a human being as concomitants of every psychic process. The essential content of this second part consists of a consideration of these psychic processes. Psychic phenomena—all activities of that "entity which is known by the names of mind, soul, spirit, consciousness, or psyche," making no artificial or arbitrary distinction between these terms—are real things, true cosmic events, solely and entirely what they appear to be. A number of novel but highly important distinctions and suggestions are made in the course of this discussion. They can scarcely be indicated within the limits of a short review. Such processes or phenomena have both qualities and quantities, and in the realm of quantity they must be regarded as not only enduring in time but as occupying space, and to time and space must be added the equally important element of degree or intensity. Thus, startling as it may seem, "the dimensions of our visual images may considerably exceed those of our bodies and, further, every inner world, which is but another name for mind or soul, is extended in all directions and as far beyond the confines of the body as its sensations and thoughts will carry it." A notion of this kind may be taken to illustrate the fearlessness with which the author pursues his ideas and deductions and the consequences to which they lead; and it should be emphasized that an intelligent and consecutive reading of his book leaves no impression of the fantastic but only of what is logically conceived and clearly apprehended. It is refreshing in these days, when biochemistry and biophysics seem sometimes to occupy the whole field of the biologist, and when students are only too often left with the impression that nothing else matters, to be reminded of the passage from Professor J. S. Haldane's presidential address to the British Association in 1906 in which he said:

"In physiology, and biology generally, we are dealing with phenomena which, so far as our present knowledge goes, not only differ in complexity but differ in kind from physical and chemical phenomena; and the fundamental working hypothesis of physiology must differ correspondingly from those of physics and chemistry."

The literary style of the author, and the print and general format of the book, all add to the pleasure of the reader.

OCULAR DIOPTRICS

It is given only to the few to possess such a mastery of the methods of mathematics as to be able to demonstrate the laws underlying much of our common clinical practice in the examination of the eyes for errors of refraction and the correction of these errors by glasses. But it seems that at least one genius of the order appears every few years. The labours of these men form the true basis of the work of the clinician, and have helped materially towards those advances in the form of spectacle lenses which in recent years have added to the great comfort of the hard-worked or over-worked human eyes. For many years the treatise on geometrical optics by R. S. Heath held the field. He was a well-known Cambridge mathematician, and professor of mathematics at Birmingham. Then came Dr. A. S. Percival, a practising ophthalmic surgeon of Newcastle-on-Tyne. Now there is a new book before us on *Ocular Dioptrics and Lenses* by Mr. G. F. ALEXANDER. He has produced

mathematical dissertations before, but in this book he launches out into a much wider field. Starting to investigate a number of intricate technical problems which have received little notice in our textbooks and teaching, he found that their elucidation compelled him to make incursions into other fields of optics which are connected with ocular refraction. He is to be congratulated upon a notable piece of work. It is a book to study.

Notes on Books

Dr. A. C. ROXBURGH's *Common Skin Diseases* was very favourably reviewed in these columns on its appearance at the close of 1932. A second edition⁴ is now published. Some fresh illustrations have been added, and also chapters on congenital affections of the skin, atrophy and sclerosis, vesicular and bullous eruptions, and the erythrodermias.

The approach of the holiday season brings us a copy of *Fifty Years on the Test*,⁵ by C. ERNEST PAIN. This, which will appeal especially to those fortunate enough to have a rod on the River Test, will interest other fishermen as well. There are practical notes on hatching and stocking, and, generally, on how to improve a trout water. There will also be found useful hints on fishing difficult places, and on casting a fly. From the same publishers we have received *For Fishermen Only*,¹⁰ by ATWOOD CLARK. The expert to whom this has been submitted for criticism reports that it is a delightful book for both salmon and trout fishermen, and that it contains many valuable hints.

The book on *Hospital Accounting and Secretarial Practice*¹¹ by F. DEAN and C. H. SPENCE has been written for the use of hospital officials and for those preparing for examinations held by such bodies as the Association of Hospital Officials and the secretarial examining authorities. It contains chapters dealing with all forms and varieties of hospital accounting, with the laws relating to voluntary hospitals, with the practice of committee work, stores, printing, correspondence, filing, the almoner's department, and other kindred subjects of the greatest importance to those responsible for the management of our hospitals. The book is clearly written and full of information, and it should be of great service to budding hospital secretaries.

The Transactions of the Japanese Pathological Society, 1933,¹² form a handsome volume of nearly a thousand pages, comprising two hundred and fifty-three separate articles, ranging over the whole field of pathology, and including papers contributed to the twenty-seventh meeting of the Japanese Society of Cancer Research. Among the many articles of interest that by O. Tamura, on the development of the heart muscle, deserves special mention. According to the author the foetal and post-foetal tissue development, at present regarded as distinct processes, form one continuous process, the plan laid down in the foetal period being maintained and resulting in the formation of three centres (sino-auricular, atrio-ventricular, and bulboastial) from which the several sections of the heart are developed. Dr. Suzuki reports that the percentage of primary cancer of the lung in the necropsies of the Pathological Institute of the Imperial University of Tokio has steadily increased from 0.1 in 1894-8 to 2.01 in 1929-32. The volume is copiously illustrated, and opens with a short obituary notice, with portrait, of Dr. M. Nishibe.

⁴ *Common Skin Diseases*. By A. C. Roxburgh, M.A., M.D., B.Ch., F.R.C.P. Second edition. London: H. K. Lewis and Co. Ltd. 1934. (Pp. xxxii + 370; 128 figures; 8 coloured plates. 16s. net.)

⁵ *Fifty Years on the Test*. By C. Ernest Pain. London: Philip Allan and Co. 1934. (Pp. 198; 8 illustrations. 10s. 6d. net.)

¹⁰ *For Fishermen Only*. By Atwood Clark. London: Philip Allan and Co. 1934. (Pp. 274. 10s. 6d. net.)

¹¹ *Hospital Accounting and Secretarial Practice*. By Frank Dean and C. H. Spence. London: Sir Isaac Pitman and Sons, Ltd. 1933. (Pp. 160. 7s. 6d. net.)

¹² Volume xxiii. 1933. Published by the Society. Editorial Office: The Pathological Institute of the Tokyo Imperial University, Japan. (Pp. 977; illustrated.)

⁷ *Ocular Dioptrics and Lenses*. By G. F. Alexander, M.B., C.M. London: Baillière, Tindall and Cox. 1934. (Pp. viii + 212; 68 figures. 12s. 6d., postage 6d.)

SATURDAY, AUGUST 11th, 1934

LONDON WATER IN A DRY YEAR

The annual report for 1933 on the metropolitan water supply reproduces in most essentials the excellent features of its predecessors.¹ During the first six months of the period covered, the water examinations were still carried on under the personal direction of Sir Alexander Houston, whose desire it had been, in view of his then approaching retirement, to preface the report with some words of farewell. That this wish of his was denied fulfilment will be matter of genuine regret to all who knew and admired his interest in the streams and wells of the London supply, and yearly welcomed his vivid descriptive surveys of the sources from which these waters flow. He possessed, indeed, in a remarkable degree a gift of establishing terms of friendship with many who had never seen him, and our sense of personal loss is a tribute to his genial memory. Such a feeling, however, for the late director in no way lessens our appreciation of the competent manner in which Mr. R. B. Floris, the deputy director, has compiled the report for 1933.

The report shows how the watch over the quality of the water supplied to London has been maintained as in the past, the policy being to increase and not diminish the precautions used. In 1933 the number of routine water samples tested was 17,259. Of this total, 4,541 were chemically examined and 12,718 bacteriologically. In addition, many other samples were examined for special purposes. Excepting the raw river water which passes through the Staines aqueduct, filtered water only is chlorinated, the chlorination process being always preceded by ammonia treatment in order to prevent the development of obnoxious tastes in the water. All the Thames waters but those of Chelsea and Lambeth were submitted to chlorination, and yielded thereafter first-class samples in percentages ranging from 90.7 for Southwark and Vauxhall to 99.1 for Sunbury. The dose of chlorine varied from 0.2 to 0.3 part per million of water. The dose of ammonia as nitrogen was usually 0.1 part per million. The first-class samples of River Lea water, after chlorination, were 92.3 per cent., and of New River water, also after chlorination, 88.3 per cent. For the deep wells, which are not chlorinated, the first-class samples in Kent were 95.7 per cent., and in Lea Valley 93.2 per cent. By a first-class sample in these cases is meant one which shows no *B. coli* in 100 c.cm. of water.

It is worthy of note that in 1933 the community of Epping afforded ample justification for certain precau-

tions set on foot by Sir Alexander Houston early in 1931, when paratyphoid bacilli appeared in the effluent from its sewage disposal plant following on a local outbreak of that fever. This discharge flows into Cobbin's Brook, which in its turn joins the River Lea at a point above the London water intakes. The area of supply concerned was clearly exposed to risk, and sterilization of the effluent by means of chlorine was forthwith begun. During the three years which have since elapsed, paratyphoid bacilli have never been absent from the raw effluent for long, and have frequently been present in substantial numbers, yet no paratyphoid fever accreditable to Epping has emerged in London. Late in 1931 another case of the fever came to light in the Epping district, and still another in April, 1933. Finally, in September, 1933, a fresh paratyphoid outbreak developed, totalling twenty-two cases. Thus the measures initiated in 1931 not only excluded the Epping infection from London throughout the inter-epidemic period, but also, as shown, armed the metropolis in advance against the second outbreak. If Epping looms like a threatening cloud above the Lea supply area, it affords at the same time an object lesson in the foresight of those whose charge it is to protect the London consumer from the dangers inherent in polluted water. The method of handling adopted there, in a particular case where infective material was demonstrably present, is of a piece with the general practice noted above as applied in the routine London water examinations, where the possibility of infection is always presumed. The high standards set and the frequency with which these high standards are attained convey to consumers an assurance of safety of a correspondingly high order. Hence London water is often well described as above suspicion.

Passing now from the satisfactory annual report and turning to the question of quantity, we approach a topic which there has been no occasion to discuss from a practical point of view in connexion with London water for a number of years. The consumption of London is, no doubt, enormous, but the storage reservoirs are gigantic, and the Thames, as the greatest river in England, might well be reckoned an inexhaustible source, the draw-off from which is curtailed, if ever, not through any shortage of flow, but rather by waiting in times of flood to let the turbid waters go by. Yet even the London undertaking, large as it is, has felt the effects of an abnormally low rainfall prevailing over the country generally for many months. For the twelve months ended December 31st, 1933, the rainfall over England and Wales was 17 per cent. short of the average. For the twelve months ended June 30th of this year the deficiency had risen to 26 per cent. At June 20th last the flow of the Thames at Teddington Weir had fallen to 230 million gallons, a shortage of 589 million gallons on the daily average for June. To prevent depletion of the London supply an Order has been issued reducing to 50 million gallons a day the quantity of water to pass over the weir before any draw-off can be made

¹ Metropolitan Water Board. Twenty-eighth Annual Report. The Results of the Chemical and Bacteriological Examination of the London Waters for the Twelve Months ended December 31st, 1933. By R. B. Floris. London: P. S. King and Son, Ltd. 1934. (10s. 6d.)

by the Metropolitan Water Board to replenish its reservoirs. The citizens, too, urged to use less water, have already responded in some measure, but an official paper recently issued roundly expresses the view that much larger economies in water can still be effected in the London area without any hardship.

Other large communities in the country are, like London, engaging the problem of the drought without appreciable inconvenience. Of the smaller urban areas, however, a number are experiencing shortage, while many rural authorities in one part or other of their districts have for months past suffered grave embarrassment, and cartage of water has begun. Such difficulties are being relieved, so far as possible, under the emergency powers to improve supplies conferred by the Water Shortage Act, and grants in aid of permanent works in terms of the Rural Water Supplies Act are being made available by the Government to a number of councils. *The private individual everywhere has a duty to second these public enterprises by observing for his own part a strict frugality in the use of water.* An example worthy of imitation has been set by the people of a northern town, who have reduced their water consumption by one-third through voluntary effort alone.

THE ENDOCRINE FACTOR IN ESSENTIAL HYPERTENSION

The clinical features of essential or malignant hypertension have long presented problems which could not be explained on the ordinary lines followed in cases of chronic, permanent, and relatively benign forms of high arterial blood pressure. It is clear that they cannot be explained on the grounds of structural changes in the peripheral vessels, having regard to its paroxysmal and rapidly progressive nature. As long ago as 1904 Vaquez, as a result of study of a case of hypertension in which he had found evidence of hyperplasia of one suprarenal, suggested a humoral mechanism for this, and considered that the suprarenal was specially to be considered in this connexion. Recent work tends more and more to show that such an endocrine factor is certainly involved. The demonstration of increased amounts of a pressor substance in the blood of hypertensives of this type is attended by very special difficulties, and claims to have effected such a proof are always rather suspect.

The probability that increased quantities of circulating adrenaline are present is strongly supported by those cases of tumours of the medulla of the suprarenal (phaeochromocytoma) in which, clinically, the symptoms and signs closely resemble those of essential hypertension. A very interesting case of this has recently been described by H. Kalk.¹ The patient was a woman of 36 who complained of "attacks" with the following symptoms: "sizzling" in the head, feeling of deafness, palpitation coming on suddenly,

followed by retrosternal pain and great anxiety. The intensity of the attacks varied; they might be very severe, stop for a minute, and then recur worse than ever.

Pallor of the face, hands, and feet was observed during the attack, and this series of phenomena might continue at short intervals for three to six hours. The patient noted that muscular movements often precipitated attacks. A variety of investigations revealed a tumour in the region of the right kidney, and on palpation and massage of the tumour region the blood pressure rose from 125/85 to 155/125 (in the interval between attacks the blood pressure was 120/80), the pupils dilated, the face became pale, and the pulse rate increased by 15 beats a minute; these changes were then succeeded in about three minutes by the usual post-adrenaline compensations—perspiration, redness of the face, slight salivation, and contraction of the pupil. The results of manipulation of the tumour were exactly similar to the manifestations of spontaneous attacks, but in the latter they were much more severe, the blood pressure, for example, rising to 240 and 300 mm. Hg and the pulse rate increasing by 30. Operation revealed a tumour of the right adrenal weighing 290 grams which was identified as a phaeochromocytoma, containing between 150 and 200 mg. per cent. of adrenaline. After removal of the tumour the crises of hypertension disappeared. Two points of interest in this case were that the tumour was diagnosed correctly on clinical grounds, and that careful examination of kidney function at no time revealed any indication of nephritis. Such a case presents us with unquestionable evidence that a tumour of this sort can produce the picture of paroxysmal hypertension, and that discharge of adrenaline is the immediate cause of the attacks.

There is no suggestion, of course, that all cases of essential hypertension are associated with medullary tumours, but the presumption that they are due to hyperadrenalinism gains strong support. Working on this hypothesis de Courcy and co-workers² adopted the plan of removing two-thirds of each suprarenal, having regard to the well-known fact that in animals removal of one gland and partial resection of the other does not materially interfere with their continued well-being. This operation, performed in two stages, was carried out in several cases of typical essential hypertension with such satisfactory results that the authors feel justified in drawing a close analogy between hyper-suprarenalism and hypertension. In support of this contention they point out that it is always possible to demonstrate hyperplasia of the suprarenal medulla in essential hypertension, and that it has recently been shown by Kuré and his associates that a vaso-constrictor body exists in the arterial blood which appears in greater quantities in cases of hypertension than in normal controls. Olivier and Meillère³ take a similar view as to the value of adrenalectomy in essential

¹ *Klin. Woch.*, April 28th, 1934.

LOUPING-ILL IN MAN

hypertension, but consider that the medullary hyperplasia is slight and that the value of unilateral adrenalectomy (which they practised) lies in the partial rupture of a pathological chain, the glands removed in these cases appearing to them quite normal. Olivier and Meillère do not, however, give sufficient morphological and histological details to be sure of the absence of hyperplasia, and are themselves puzzled at the success of their operations in relieving the hypertension.

From the purely therapeutic point of view another way of preventing the hypertensive crises in these cases is to provide a vascular reservoir which could be utilized in an emergency, and thus prevent the dangerous rise in blood pressure. Working on this plan Adson and Brown⁴ performed bilateral section of the anterior roots from the sixth thoracic to the second lumbar, thus cutting off the vaso-constrictor supply to a large vascular area, denervating the suprarenals, and removing the motor innervation of the abdominal wall, which would in a crisis tend to maintain the intra-abdominal pressure. The results of this operation in a female patient with a severe and progressive form of hypertension were a marked fall in systolic pressure and a relatively unaffected diastolic. The latter finding was due to the already considerable hypertrophy of the arteries, a return to normal diastolic pressure at that stage being impossible. These results are of great interest, but cannot compare in value with those obtained by removal of the gland tissue. The latter operation obviously has more to commend it in that it seems to attack the basic factor in the disease. None of these results give us the slightest information as to what may be the stimulus to over-secretion of the suprarenal medulla, but this appears to be the situation in most endocrine syndromes.

LOUPING-ILL IN MAN

There is no more obscure and difficult study than that of virus infections of the central nervous system. Although some types of encephalitis and encephalomyelitis, both in man and more particularly in animals, are readily recognizable, and of these some are easily transmissible, we need only recollect the difficulties which beset the experimental study of encephalitis lethargica and post-vaccinal encephalitis, and the state of uncertainty and frustration in which these studies were abandoned, to appreciate that even a well-defined type of the disease may baffle the closest investigation. With sporadic cases, such as are reported from time to time, presenting the features of an encephalitis, the likelihood of reaching any aetiological conclusions is even less. The structural changes in the brain vary in their nature singularly little between one type and another, though they may differ in distribution and extent, and the only hope of identifying the responsible agent depends on the success of animal transmission and on further methods of investigation in which comparatively few bacteriologists are experienced. It is,

in fact, not only almost certain that there are varieties of encephalitis the cause of which is unknown, but quite possible that cases appear of which the nature passes entirely unrecognized. Peculiar interest therefore attaches to the recent report of Rivers and Schwentker¹ of four cases of encephalitis attributed to the virus of louping-ill. It should be said at once that but for the circumstances in which these cases occurred and the immediate availability of facilities for expert investigation, there is not the smallest likelihood that their nature would have been recognized or even suspected. Louping-ill is a disease of sheep, the features of which have recently been discussed by W. S. Gordon in these columns.² The virus of this disease has been the subject of experimental work at the Rockefeller Institute in New York, and three of the cases described were in investigators engaged in this work; the fourth was that of an investigator in London whose subsequent visit to America enabled Rivers and Schwentker to inquire into the features of his illness and to perform the serological tests by which its nature was determined. The features of the illness were in each case fever, drowsiness, headache, and photophobia, lasting for a week or rather less after confinement to bed, with a moderate pleocytosis in the cerebro-spinal fluid (about 60 leucocytes per c.mm.). All the patients recovered completely. The proof of the nature of the illness rests on protection tests in mice with serum obtained after recovery, and although the results of these tests are not entirely clear-cut, their number and the exactitude with which they were performed, together with a profusion of control tests, must command conviction. It is worthy of note that the symptomatology is far from being distinctive; it is, in fact, singularly vague, and such a case arising in other circumstances would inevitably remain undiagnosed. Although there is no direct evidence that this form of encephalitis can be naturally acquired in man, the fact of its occurrence will serve to renew interest in this obscure field of work, and perhaps to prompt further investigations in cases of similar clinical type. It should be generally known that, although brain from a fatal case is naturally the most fruitful material for laboratory investigation, the serum of a recovered case may, as in Rivers and Schwentker's cases, yield valuable information, and should therefore be obtained and preserved whenever it is hoped to gain further light on a case of suspected encephalitis. Burnet³ in Australia has recently suggested that Australian x-disease—an epidemic of encephalitis which occurred in that country in 1917-18—may have been due to the same (louping-ill) virus. The human symptomatology is similar, and the distribution of cases is said to have been more consistent with an animal origin than with transmission by human carriers. On the other hand, louping-ill in sheep is unknown outside North Britain, and its vector, the tick *Ixodes ricinus*, is not found in Australia. The serum of cases of x-disease obtained sixteen years after the attack does not neutralize louping-ill virus. There is therefore no apparent prospect of either confirming or disproving this interesting but highly speculative suggestion.

FEE-SPLITTING IN CANADA

After the ventilation which fee-splitting or dichotomy had in these columns about fifteen months ago, this unpleasant topic seems to have receded into the background again so far as England is concerned. That it still troubles our colleagues on the other side of the Atlantic may be judged from an article on "The Difficulties of the Profession," by Dr. Harris McPhedran, in the *Canadian Medical Association Journal* for July. After discussing the hard times through which the general practitioners of Canada have been going in the past few years, and the need for consolidating the profession of Ontario as a self-controlled unit before health insurance in some form comes, Dr. McPhedran writes: "There are, too, difficulties and dangers in the ranks of the profession. These appertain largely to the practice of surgery. One hears complaints frequently from skilful surgeons that many general practitioners are attempting to solve surgical problems for which by training and experience they are quite unfitted. It is admitted by all surgeons that many general practitioners are sufficiently experienced and qualified to deal with the more common surgical diseases that are encountered in general practice. But there are others who, without any justification whatever, attempt the more difficult operations solely for the sake of the monetary compensation, or, in lieu of operating themselves, refer their patients to one who, without much right, assumes the title of surgeon, and will secretly divide with them the fee obtained for operating on their patients. In some way legitimate surgery must go to those qualified by experience and training in the science and art of this branch of medicine. Again, by some means, secret division of fees must be stopped, as the greed of gain on the part of those who are parties to this procedure tends to unnecessary operations, and in the case of necessary operations leads to the choice of a surgeon who tacitly admits his inferiority in offering to divide his fee." Plain words, these. But fee-splitting is an ugly thing—a form of commercialism which threatens the foundations of medical practice.

PICTORIAL ART AND THE MEDICAL PROFESSION

In connexion with the Annual Meeting at Bournemouth an exhibition of pictorial art by members of the medical profession had been collected by Mr. Norman L. Silvester, curator of the Russell-Cotes Art Gallery and Museum, and was on view in that fine building. Special attention was attracted by two fine examples of pinpoint needlework contributed by Dr. Margaret Vivian of Southbourne, and described as "Trees" and "Bushy Park in Bluebell Time." In happy contrast were the swift impressions of landscapes in oils and water-colours by Sir Leonard Hill and others. Mr. E. B. Waggett exhibited a dozen delightful works in pastel, while Dr. T. G. Stevens, in the same medium, recalled London scenes. Sir Harold Gillies depicted hill country in Scotland, and other subjects. Opening the exhibition, the president, Dr. Watson Smith, remarked that the necessary cultivation by doctors of imperturbability was assisted by such hobbies as this. No doctor could afford to be without some hobby, and one of the highest forms of happiness was to be found in art. Sir Leonard Hill, in a short address, referred to the "extraordinary interest to be found in art. It gave great

relief alike to the general practitioner and to the research worker. He explained how it was now possible to identify pictures by scientific means. A low-power microscope with good illumination brought out variations in brushwork, and thus specified particular painters. Similarly, the style of handling foliage varied, and details were disclosed by magnification. The application of x rays might reveal the existence of one picture beneath the apparent one, sometimes with important results. Ultra-violet rays employed with Wood's glass caused certain substances to fluoresce, thus defining the composition of certain pigments, indicating some as modern and not ancient. Micro-chemical methods were applicable to small portions of paint removed by a hypodermic needle. Such portions could also be cut into sections and examined microscopically. The nature of the media used could be identified, such as gesso, egg-white, and oil, and so identification of certain painters be established. The ancients had only a limited number of colours, all the constituents of which were known. Modern artists also had pigment preferences, and scientific methods were applicable in cases of disputed authorship. Some of those who visited the exhibition traced a special significance in the words on the wall which faced the entrance: "Art is the most immediate form of knowledge." Certainly, the excellence of technique and composition in the exhibits revealed an accuracy of observation and a sensitiveness to effects which medical practice induces and in which medical practitioners can find recreation and relief. The exhibition will remain open throughout August.

INGROWING TOE-NAIL

The factors underlying the production of the common disability of ingrowing toe-nail are by no means clear, and there is a corresponding lack of uniformity in the methods of treatment. These vary between the simple palliative measures of chiropody and extensive plastic operations. In an attempt to discover the method giving the maximum freedom from recurrence and the shortest convalescence Keyes¹ has analysed the results of a series of 110 operations performed by twenty-six different surgeons. That which he describes as the "usual" operation has long been associated with the name of Watson Cheyne, and consists in the removal of a wedge of nail about a quarter of an inch wide, together with the underlying nail bed and nail matrix and sufficient of the nail wall to include the ulcerated area. This operation was performed sixty times: the results were the best in the series, showing only 5 per cent. of recurrences and an average healing period of sixteen days. The "Winograd" operation, by which is meant excision of a strip of nail and its matrix, leaving intact the nail wall, gave 11 per cent. of recurrences in thirty-four cases and a healing time of fifteen days. Simple avulsion of the nail was followed by recurrence in seven out of nine cases, with an average healing time of thirty-seven days. Excision of the whole nail and the matrix gave freedom from recurrence in the three cases on which it was performed and a healing time of twenty-three days. Wedge resection from the nail wall with the object of allowing more space for the ingrowing nail was followed by at least one recurrence

¹ *Journ. Amer. Med. Assoc.*, May 5th, 1934, p. 1458.

in four cases. These were the methods employed in the series under consideration, but this list is by no means exhaustive. The results would indicate that the operation of Watson Cheyne gives a sufficiently high percentage of cures with a fairly short convalescence. The aesthetic effect, in addition, is much better than that which follows excision of the whole nail and its matrix, though the latter would appear to be more certain in its results. In every operation depending in principle on permanent removal of part or whole of the nail thorough excision of the matrix is essential to success, and most recurrences are due to failure to accomplish this. The difficulties experienced by Dr. Keyes with his local anaesthesia and haemostasis do not become apparent to surgeons who use routine general anaesthesia and secure haemostasis for all operations on the foot by a tourniquet, preferably of the Esmarch bandage type, which is finally fixed around the middle of the leg and not around the base of the toe.

BARBITURATE POISONING IN FRANCE

Drs. C. Flandin, F. Joly, and J. Bernard have written an account of Parisian experience of poisoning by hypnotics, with special reference to barbiturate intoxication.¹ It is only a few weeks since we reviewed a volume on the same subject by Lille physicians.² The intensive interest in barbiturate poisoning in France is explained by a statement in the preface to the latest publication to the effect that the prevalence of this condition has suddenly increased since 1930, and that a single hospital had sixty-two cases in the last eighteen months. The authors estimate that every year in Paris there must be thousands of cases of barbiturate poisoning of greater or less severity. The augmentation in the number of severe cases is due to the fact that these drugs are becoming the method of choice for suicide among certain classes, and have completely ousted laudanum. It is of interest to note that recently luminal (phenobarbitone) has provided twice as many cases of poisoning as veronal (barbitone), and that female cases are two or three times more common than male. The authors have therefore had a rich supply of clinical material on which to base their description of barbiturate poisoning, and they give a detailed account of the clinical symptoms and pathological changes observed in these cases. In regard to treatment they support the use of large doses of strychnine. They recommend doses of from 1/6 to 5/6 grain (0.01 to 0.05 gram), repeated hourly if necessary. This method requires the constant and watchful care of a medical man, who must be fully conversant with the initial signs of strychnine poisoning. The authors conclude that although this method of treatment does not provide miraculous cures, yet it does save a number of patients who would otherwise certainly die. They conclude that strychnine, even in the large doses mentioned, has a disappointingly feeble action as a respiratory stimulant, and recommend for this purpose coramine injections or inhalation of carbogen. The authors appeal for a more rigorous control of the sale of barbiturates, which in their view are social poisons of greater importance than opium or cocaine, and but little

inferior to alcohol. Much has been written in this country for and against the barbiturates, and the defenders of these drugs have been able to show that at present they do not appear to constitute a widespread social danger on this side of the Channel. The evidence set out by Flandin, Joly, and Bernard indicates, however, that in recent years in France the abuse of these drugs has grown in a remarkable fashion.

THE HUNTERIAN MUSEUM

The enlarged outlook in the working of the Museum of the Royal College of Surgeons of England, which had its inception and early development under the conservatorship of Sir Arthur Keith, appears in full fruition in the annual report of the new conservator, Dr. John Beattie. While there is no intention to allow of any relaxation in the endeavour to maintain the present position of the Museum as one of the finest in the world, surgical research will, for the future, be added to the functions of the Museum and take equal place beside the collection of pathological specimens. The organization of the research side appears now to be complete, except for certain alterations and additions required in the laboratories at the College of Surgeons. The conservator has been appointed head of the department as director of research, with control over the laboratories at the College and over the Buckston Browne Surgical Research Farm at Downe. The latter was formally opened during the past year, and is now in full working under the immediate direction of the Master, Sir Arthur Keith. One-half of the annual report is taken up with the subject of research, and the following list of workers, and the investigations on which they are engaged, will give some idea of the extent of the present activities of the department. Mr. J. H. Thompson, on parathyroid extracts; Mr. H. Jackson Burrows, on tissue culture and osteochondritis juvenalis; Sir Charles Ballance, on sympathetic-peripheral nerve anastomoses and the effect of ablation of the facial nerve on the facial nucleus; Mr. A. E. M. Woolf, on diverticulitis; Mr. V. E. Negus, on ciliary activity; Lieut.-Colonel E. P. Argyle, on roaring in horses; Mr. H. P. Winsbury-White, on the spread of pelvic inflammations; Mr. L. O'Shaughnessy, on the surgery of the lung, heart, and oesophagus, and on traumatic shock; Dr. D. Slome, on carbohydrate metabolism; Mr. G. C. Knight, on achalasia; Dr. R. A. Willis, on teratomata; and Mr. T. Barnett, on decerebrate rigidity. In addition to this experimental work, numerous investigations of an observational nature have been undertaken in the Museum, as in previous years, chiefly in the osteological and anthropological sections. These, together with the donations which have been made to the Museum during the year, are described in the reports of the curators of the several departments. Of particular interest is Mr. T. D. McCown's account of the excavations at the Mount Carmel caves, from which three blocks containing fossil skeletons were transferred to the College in 1932. The difficult operation of excavating these skeletons from the solid breccia matrix in which they are embedded has already been partially accomplished by Miss G. M. Collett and Mr. W. C. Willmott. The Museum has suffered a severe loss in the retirement of Mr. H. R. Burne, F.R.S., who has for many years occupied the post of physiological curator.

ONE HUNDRED AND SECOND ANNUAL
MEETING
of the

British Medical Association

HELD AT BOURNEMOUTH, JULY, 1934

THE SECTIONS

SUMMARY OF PROCEEDINGS

During the next few months there will be published in the BRITISH MEDICAL JOURNAL the opening papers communicated to the Scientific Sections of the Annual Meeting at Bournemouth. The reports of discussions in this and successive issues are intended to give members who were not present a general idea of the proceedings.

SECTION OF MEDICINE
Thursday, July 26th

B. COLI INFECTION

Professor D. M. LYON (Edinburgh) opened a discussion on the aetiology and treatment of *B. coli* infection. In all cases, he said, the original source of the infection was doubtless the bowel, and he discussed the various possible methods of spread to other sites. Spread to the urinary tract might be by lymphatics, blood stream, or by direct penetration; there might be invasion of the portal stream or of the thoracic duct, with consequent general spread. In pyelitis most writers seemed to favour blood spread to the kidney. Urinary infection occurred at all ages, and was more frequent in women than in men at all ages. In men it was nearly always associated with some degree of obstruction, and obstruction and long retention of urine were probably the most important aetiological factors. Pyelitis was common about the middle of pregnancy, and this might be due to the dilatation of the renal pelvis, which was almost constant in this condition. Infection of the gall-bladder took place in much the same way as in the urinary bladder. The bacilli invaded the wall and formed a focus for infection of the bile. But factors other than the mere presence of organisms were probably necessary to establish infection; among these might be reckoned gall-stones, chemical and toxic damage to the mucous membrane, and defective drainage. True *B. coli* septicaemia was exceptional. In treatment special attention must be given to correcting lesions interfering with free drainage of the urinary and biliary systems, and every care should be taken to ensure a healthy condition of the bowel, both constipation and diarrhoea being carefully avoided. Intestinal antiseptics were of little avail; calomel in non-purgative doses was probably the most useful drug; high colon lavage might be employed. There was some evidence that excess fat in the diet favoured penetration of the bowel wall by *B. coli*, and all writers agreed that in acute renal infection milk must be avoided, and butter and eggs were usually restricted. In the acute renal urinary infections the treatment was standardized: bed, warmth, large doses of alkali, barley water, fruit juice, and glucose drinks up to four pints a day. If alkali treatment failed alternate treatment with antiseptics hexamine was the most generally used; for little effect in infections above the bladder as too little formaldehyde was evolved above that level. The ketogenic diet had proved successful in some cases, but it was nauseating, and would probably be reserved for the most resistant cases. In chronic biliary infection efforts must be made to secure a free flow of bile.

Dr. CUTHBERT DUKES discussed the conditions which predisposed to urinary infection with *B. coli* when the functions of the bladder were temporarily deranged after surgical operations, basing his observations on a series of 214 cases of retention of urine following excision of the rectum. He first dealt with certain factors that might be supposed to influence infection but did not: changes in the nursing personnel, type of operation, and minor degrees of deficiency in renal function (that is, of a degree insufficient to make the case inoperable) in no way affected the incidence of infection. The four chief factors were sex, age, duration of retention, and general health. Sex was the most obvious factor, infection occurring in 69 per cent. of women but in only 36 per cent. of men. Next to sex old age was the most important; in women under 60 only 62 per cent. developed infection, as against 86 per cent. over 60, and a similar disproportion was seen in men. This was attributable in women to loss of muscle tone and in men to the increasing incidence of prostatic disease. Both resulted in longer periods of retention, and figures showed clearly that the longer the period of retention the greater was the incidence of infection. Lastly, the general health was clearly an important factor; early cases were in a much better state of health and showed a much lower incidence of infection.

Dr. C. M. WILSON discussed the advantages of the ketogenic diet for chronic cases in adults. Of 100 consecutive cases treated with this diet eighty-eight were freed from infection and twelve were failures, while there was relapse in fifteen. Professor Lyon had said that this diet should be reserved for cases which had failed to respond to other methods, but this was a surprising conclusion in view of the fact that it was generally admitted that no other method could offer the patient so hopeful a prospect of cure. If a successful result was to be obtained the pH of the urine must be brought down to 5, and must give a strong positive ferric chloride test. Moreover, the ketosis must be kept at this level throughout the twenty-four hours, and evening and morning tests were essential. The treatment must be pushed from the start, and a positive ferric chloride test should be obtained in three or four days. The patient should not be kept in bed, but should pursue his ordinary avocation. Exercise was helpful. With care the diet was not necessarily very unpalatable; but nausea was common, vomiting not rare, the pulse increased in rate, and weight was often lost.

Dr. C. M. HINDS HOWELL spoke of the importance of prostatic infection in aetiology; prostatic massage and diathermy were important aids to treatment. Bacteriophages he had found disappointing. Ultra-violet light and direct sunlight must be used with the greatest caution. He had had difficulty in getting the urinary pH below 5.8 with a ketogenic diet, but large doses of ammonium chloride would ensure it. Dr. E. P. POULTON emphasized the value of protein in securing a ketosis. He was now using calcium chloride: a 7½-grain pill coated with salol and given six times a day produced a pH of 5 without dieting. Dr. W. H. F. OXLEY asked whether any further advance had been made in the preparation of the ketogenic diet in relation to its bactericidal activity. Dr. DOROTHY HARE spoke of the value of the B.D.H. capillometer as an easy means of determining the pH, and recalled Dr. Lepper's experiments on the effect of slight trauma in producing infection. Dr. E. HOW WHITE (Bournemouth) pleaded for the more prolonged and careful treatment of acute cases, thus preventing the occurrence of the chronic case. Dr. J. A. RYLE suggested a classification into (a) acute, without obstruction; (b) acute, with obstruction; (c) chronic, without obstruction; and (d) chronic, with obstruction. In (a) adequate alkalinization was not sufficiently frequently secured, but with large enough doses it should prevent chronicity in a greater number of cases. In (b) and (d) surgical assistance was generally required. Unilateral loin pain was very suggestive of an obstruction, and early diagnosis might frequently save patients from prolonged and fruitless dietetic treatment. Dr. S. C. DYKE (Wolverhampton) pointed out that the cause and treatment of *B. coli* infection must depend on the anatomical lesion. He described cases of so-called acute

pyelitis in women in which the kidneys removed during life or after death showed cortical abscesses and septic infarcts from which *B. coli* were grown. He thought infection occurred via the blood stream, and emphasized the need for rest in treatment.

DEMONSTRATION OF OXYGEN TENT

Dr. E. P. POULTON demonstrated the use and value of the oxygen tent in the treatment of pneumonia. For practical purposes, he said, there were two ways of giving oxygen: (1) by nasal catheter, (2) by the oxygen tent. The latter was widely used in America, but its employment in this country was only just beginning. The tent was more effective than the nasal catheter, and this had been proved both experimentally and clinically. With the help of the Medical Research Council it was now possible to send out at the request of any medical man an oxygen tent in the charge of a fully qualified physical therapist. Only the actual expenses would be charged for; but it was hoped that any patient who had benefited from the treatment would make a donation towards the cost of an oxygen therapeutic service to be constituted on a voluntary basis.

(Further information can be obtained from the Secretary, 25, Upper Wimpole Street, W.1 (telephone, Welbeck 1627), or from the Medical Section, British Industries House, Marble Arch, W.1.)

SECTION OF SURGERY

Thursday, July 26th

BAD SURGICAL RISKS

Under the chairmanship of Professor GREY TURNER (Newcastle-on-Tyne) Mr. G. GORDON-TAYLOR opened a discussion on bad surgical risks.

Mr. Gordon-Taylor said that, apart from the technical competence of the operation, the organization of the theatre, and the environment in which the surgeon worked, there were many factors which combined to determine the success or failure of a surgical operation. He did not propose to turn the discussion towards the consideration of patients who were bad risks because of the magnitude of the surgical measures intended, however justifiable. He was to envisage the operated, not the operation, and to take as his criterion of a bad surgical risk Rooke's definition of "a type of patient whose prospect of recovery from active surgical treatment falls much below the average." He detailed the various causal agencies in determining whether a patient was a bad surgical risk: (a) aetiological factors of race, sex, age, and heredity; (b) bodily conformation; (c) previous habits; (d) antecedent or intercurrent disease; (e) psychology of the patient; (f) the severity of the present ailment; and (g) the type of operation proposed. He regarded it as difficult to controvert the view that members of the Jewish faith were bad surgical risks. Operations in women were, if possible, to be avoided during menstruation, pregnancy, and parturition. A long-lived ancestry was a precious possession. The psychological undesirables were those who required no persuasion or over-persuasion; the apprehensive patient; the man with huge piles of books on the tables at each side of his bed; the man with the rapid pulse and the stack of French novels around him; and, likewise, the individual who was reading his paper upside down. It was a commonplace that clergymen, doctors, nurses, actors, and those of an artistic temperament were poor risks. Mr. Gordon-Taylor then referred to beneficial pre- and post-operative measures in the different fields of surgery. He instanced the change of outlook since the introduction of iodine therapy in the surgery of thyrotoxicosis, and dwelt with some detail on the choice of operation in peptic ulcer. He advocated exteriorization methods of the Paul-Mikulicz type in carcinoma of the colon.

Mr. ERNEST MILES said that the opening speaker had dealt exhaustively with the broad aspects. He himself proposed to speak purely regarding the risks in rectal surgery. While there were only two reasons for operation

in haemorrhoids—namely, protrusion on exertion so that the patient became somewhat of an invalid, and repeated haemorrhages—stoppage of the latter by surgical means was a grave risk where cirrhosis of the liver or high blood pressure was present. Operations for fistulae were not dangerous to life except where pulmonary tuberculosis existed and was the exciting cause. Recto-sigmoidectomy for procidentia recti, even though it involved the opening of the peritoneal cavity, had carried in his hands no operative mortality. Cancer of the rectum, in contrast to non-malignant conditions, was a very different affair. Untreated, there was a mortality of 100 per cent. in two to four years. A disease of such lethal nature demanded drastic measures, and the only radical operations based on a sound pathology—his one-stage abdomino-perineal operation, the two-stage abdomino-perineal operation of Coffey, and the perineo-abdominal operation first suggested by the chairman—all demanded a great deal of the patient. In the early days of the one-stage operation the mortality was about one-third. At the present time, with our knowledge of the demands made by the operation, with our methods of inducing anaesthesia, with improved pre- and post-operative treatment, and with routine blood transfusion, the operative mortality had been reduced to 10 per cent. Careful pre-operative examination by a physician was insisted on. Every means within his power should be employed by the surgeon to get the patient to the optimum state before operation. Obese and highly strung patients particularly required careful preparation. The toxic patient, as evidenced by a sallow, earthy complexion and furred tongue, was a bad risk. The chief cause of this was septic absorption in the colon. Where this was not associated with stricture, he advocated high colonic lavage with dettol, two drachms to the pint. Where stricture was present he advocated caecostomy. The so-called tube-caecostomy was valueless; he brought the caecum up to the surface, and made an opening of one and a half inches diameter.

Mr. E. FINCH (Sheffield) said that adequate pre- and post-operative treatment was the best prophylactic against such lay press statements as: "The operation was successful, but the patient died." The family doctor should be able to assist the surgeon in great measure by his knowledge of the patient's antecedent history. It might be superfluous to mention it, but a correct diagnosis was very important in assessing the risk. Physiology was gradually elucidating what underlay a "poor resistance," and dehydration and acid imbalance were being properly treated. He was of opinion that blood transfusions were better given before than after operation. Early surgery in biliary cases was successful surgery; once jaundice had occurred the risk was increased. The appearance of the patient was of more import in renal cases than tests of function.

Dr. M. DANZIS (Newark, New Jersey) declared that he would not regard American Jews as presenting increased surgical risks. Mr. McADAM ECCLES thought the Continental Jews greater risks than British Jews. He would include among bad risks those who had recently suffered from insomnia, those who were affected severely by tropical heat, and those who were "bad sailors." Mr. J. RUSSELL (Glasgow) felt strongly that a close association between anaesthetist and surgeon was desirable in assessment of risk. The possibility of using local anaesthesia, either alone or with a view to cutting down the amount of general anaesthetic, should always be considered. He preferred never to add adrenaline to the novocain in patients of the hyperthyroid type. Mr. MASTERMAN contrasted the surgical risks in Arabs and Jews in Palestine, to the detriment of the latter. The main reason was that fear made them postpone operation till the case was advanced. Mr. R. L. SPITTEL (Colombo) thought that the apparent increased risk in Indians was possibly due to the surgeons not being able to specialize enough in their different ways. Mr. R. B. BLAIR (Hull) regarded nervous patients as usually very satisfactory patients. Mr. J. ARMSTRONG (Ballymena) claimed that the quality of the "material" handled by a country practitioner who did occasional surgery made up for deficiencies in investigation and equipment. Dr. W. N.

LEAK (Winsford) advocated large doses of vitamin A in the preparation of the patient, and Mr. BASIL ROOKE (Boscombe) thought the country labourer was a typical good risk. The cheerful fat person was a better risk than the doleful obese.

Mr. GORDON-TAYLOR, in reply, agreed with Mr. Miles in deprecating tube caecostomy. He disclaimed too much severity in his attitude towards Jews as surgical risks; there were many other factors. He joined with Mr. Russell in his advocacy of the advantages of local anaesthesia.

POST-OPERATIVE MANAGEMENT OF EMPYEMA CASES

Mr. G. A. MASON, in a short paper on the post-operative management of acute empyema thoracis, referred to the care of the wound and to the frequent necessity of converting siphon drainage into the open variety of drainage. He stressed the importance of maintaining a cavity was left in which pus was almost certain to accumulate and give rise to toxæmia and the formation of a chronic empyema. There was no constant rate of expansion of the lung, and so the decision for removal of the tube was made on radiograms showing complete expansion. It was sometimes said that prolonged use of a drainage tube led to chronic empyema, but the reverse was far more often the case. Patients could follow their occupations in the later stages with a tube in position. Mr. Mason favoured open-air treatment and the beneficial tonic effect of massage to the limbs. Irrigation of the cavity in the early stages was probably free from danger if simple measures for warming the fluid and avoiding undue increase of pressure were followed. Reflex collapse, air embolism, and cerebral abscess were unlikely due to a standstill before the cavity was completely obliterated, and rarely the lung remained completely collapsed. Irrigation with solvents such as pepsin and eusol should be tried with a view to a chemical decortication, but where success did not follow, more radical and severe procedures, such as thoracoplasty and open decortication, were indicated. Mr. PHILIP TURNER said that the bad results were more commonly due to inadequate after-treatment than to deficiencies in operative technique. His procedure, after two days' simple drainage, was to apply a large Bier's cup to the wound once daily, making two or three applications. This withdrew pus, and, by the suction, promoted expansion of the lung.

SECTION OF OBSTETRICS AND GYNAECOLOGY Thursday, July 26th

OVARIAN CAUSES OF PELVIC PAIN

With Mr. W. S. RICHARDSON, a Vice-President, in the chair, Professor DANIEL DOUGAL (Manchester) opened a discussion on ovarian conditions as causes of pelvic pain. Professor Dougal stated that the object of the discussion was to decide what conditions of the ovary produced pain. The anatomy of the organ was described, and it was pointed out that trauma, by rupture of a follicle, could occur on the surface. This trauma varied greatly in different individuals, and depended upon the activity of the anterior part of the pituitary gland. Referred pain probably never occurred at all, unless from a peritoneum irritated by ovarian disturbance. The pain was discussed under the headings of functional, mechanical, inflammatory, and neoplastic. Nature had provided that the ovary appeared insensitive to the normal distension of the follicle. Medical men might, in patients who complained of ovarian pain, deny that the pain existed, and label the patient hysterical, assume that the threshold of the pain had been lowered, as in neurasthenia, or, lastly, attribute the pain to local disease. The speaker himself took the view that a patient with a low pain threshold could and did feel pain and discomfort at the time of follicular rupture. Treatment in the first place was to

ensure physical, mental, and emotional rest. Puncture of cysts and removal of the ovary were useless and unnecessary measures. Varied results were to be expected from presacral or periarterial sympathectomy, and it was to be expected that organotherapy would be likely to give the best results. Brief reference would be made to mechanical disturbances. Retroversion of the uterus and prolapse of the ovaries did undoubtedly cause discomfort occasionally. Varicocele of the ovarian veins was of doubtful clinical importance. Inflammation of the ovary was well recognized as a cause of ovarian pain. Endometrioma was the exception among ovarian tumours as regards ovarian pain.

Professor ANDREW H. DAVIDSON said he realized how the subject bristled with difficulties. Many medical men had suffered as a result of neurasthenic patients in whom oophorectomy had been done for doubtful ovarian disease. The speaker had seen two undoubted examples of "Mittelschmerz," and had found hard, white, ovaries with a thickened cortex. Shaving off the cortex proved quite useless. Periarterial sympathectomy of the ovarian plexus should be tried to relieve this condition. Prolapsed ovaries certainly caused pain and discomfort, and he thought that varicocele of the broad ligament, especially if associated with retroversion, was a condition that produced severe ovarian pain, and that Gilliam's operation would relieve the condition. Ovarian dysmenorrhoea was produced by endometriomata of the ovary. Professor Davidson had little faith in the idea that the small cystic ovary produced pain. His views on the part played by a neurasthenic state in this condition, and also on the way in which in hysteria the patient fixed her attention on her normal ovaries, coincided exactly with those of Professor Dougal. Rubin's test was frequently of use in the establishment of disease of the Fallopian tubes and ovaries, and if no disease was found the patient should be told of it.

Dr. GERTRUDE DEARNLEY said she was constantly being sent patients who had been told they had ovarian pain, but who most certainly had not this condition. Occasionally a demand was made for double oophorectomy in the patient, who might be a young woman. Retroversion of the uterus with prolapsed, tender ovaries would certainly cause ovarian pain. Dr. Dearnley agreed with the opening speakers that a polycystic ovary could produce pain in a neurasthenic patient. Often these cases had associated mental depression, and the only treatment that seemed to give any hope was the subcutaneous injection of ovarian hormone preparations, especially progynon in 1 c.cm. doses.

Dr. JOHN FAIRBAIRN said he was sorry to have heard the constant reference to neurosis in the discussion. It was realized that ovarian pain was now mental, and none the less a very real pain. He thought that the pain in dyspareunia, ascribed to a prolapsed ovary, was nearly always due to mental upset and disturbance, and not to a "mechanical displacement." Before the abdomen was opened the surgeon must satisfy himself that an obvious pathological condition was present. Mr. GREEN-ARMYTAGUE thought that a number of young women with ovarian pain suffered in reality as a result of some condition such as scoliosis or lordosis. He deplored the use of so-called ovarian extracts in cases of possible ovarian pain, and believed that the action of these preparations was due to the irresponsible insertion of the pessary or the promiscuous use of Caesarean section. No mention had as yet been made of haematoma of the ovary or of ovarian pregnancy. He had seen cases in which operative cure of a retroverted uterus did cure ovarian pain. Professor F. J. BROWNE said that left-sided pelvic pain was a great difficulty for the general practitioner. It was a serious matter when these cases were labelled "ovarian pain." He knew one clinic which treated all such cases with a large dose of salts, and the patients did not return. He disagreed that ovarian tumours did not give rise to pain, and was not prepared to see the small cirrhotic ovary displaced from its position as a cause of pain.

THE SECTIONS: SUMMARY OF PROCEEDINGS

Sir EWEN MACLEAN (Cardiff) did not think there was any other subject in the medical curriculum in which an organ was so wrongly blamed as the cause of symptoms. Dr. BLOOMFIELD described a case of a woman who always complained of violent pain in the right ovarian region. After palliative treatment had failed, an apparently normal ovary was removed, with apparent cure of the pain. She described cases of endometriomata of the ovary which had freedom from symptoms for six to eight months. Mr. ALECK BOURNE said that he was constantly sent cases of left iliac pain, and that those who sent the cases nearly always ascribed the pain to the ovary. The chief reason for doubt as to the correctness of this diagnosis was that oophorectomy failed to produce a cure. He did believe that a prolapsed ovary and that an ovary containing a tense cyst could both cause pain. Dr. J. S. ENGLISH (Singapore) described ovarian pain caused by worm infection of the intestine and bowel. Dr. W. H. ASHMORE (Dublin) had been disappointed not to hear the "early cystic ovary" mentioned as a cause of pain. Resection of the cystic portion cured the pain. Dr. A. E. CHISHOLM (Dundee) thought that a diagnosis of hysteria should only be made as a last resource in cases of unexplained ovarian pain. Examination without an anaesthetic was more important than examination under anaesthesia. Undoubted ovarian tenderness was accentuated by a low state of general health. Constipation was an undoubted cause of left iliac pain. He would suggest that a cystic ovary was due to under- or over-secretion of prolactin. Mr. W. S. RICHARDSON (Bournemouth) classed his cases of ovarian pain into the following aetiological groups: inflammation, torsion, pressure, endometrioma, neurasthenia, and haemorrhage. Chronic appendicitis, when the organ was placed in the pelvic position, was frequently a cause of ovarian pain. Removal of the ovary was, of course, unnecessary in these cases.

Professor DANIEL DOUGAL, in reply, said that he disagreed with Professor Browne that pain was a common symptom of ovarian tumours. He hoped that as a result of the discussion there would be fewer cases in which the ovary would be wrongly blamed for pain for which it did not account. Professor DAVIDSON (Dublin) wished to emphasize the great fault that was committed by doctors who branded their patients with the label of "ovarian pain." It was a condition that took much to undo.

The meeting concluded with a film illustrating the operation of Caesarean section performed by Mr. W. S. RICHARDSON of Bournemouth, who discussed the various points during the demonstration.

SECTION OF NEUROLOGY, PSYCHOLOGICAL
MEDICINE, AND MENTAL DISEASES
Thursday, July 26th

ORGANIC AND FUNCTIONAL NERVOUS DISORDERS

With Dr. EDWARD MAPOTHER, a Vice-President, in the chair, a discussion on the differential diagnosis of organic and functional nervous disorders was opened by Dr. GEORGE RIDDOKH and Dr. A. A. W. PETRIE.

Dr. Riddoch defined the term "functional," for the purposes of discussion, as indicating symptoms which were primarily psychogenic, and "organic" as those which resulted from abnormal physical alterations in the nervous system. A medical history, he said, should recapitulate the life of the patient as a whole. The history of a psychoneurotic showed a tendency to face trouble badly. He discussed the physical signs of organic nervous disorders, as opposed to those of hysteria, including paralyses, sensory disorders, and fits. Emotionalism did not necessarily mean that the patient had not some organic illness. The investigation of the behaviour of the individual in the past and in the present, coupled with an analysis of symptoms and signs, was the essential basis upon which diagnosis depended.

Dr. Petrie also stressed the fact that consideration of the patient's whole make-up and circumstances often rendered the diagnosis clear when consideration of symp-

toms left it obscure. He discussed the hypochondriacal attitude of mind in regard to the patient's valuation of his symptoms. He dealt at length with the neuroses—hysteria and its subsidiary, the traumatic neurosis, neurasthenia, anxiety neurosis, and various mixed types, and differentiated it from the debility following severe illness or associated with chronic toxæmia. He then considered the varied manifestations of anxiety states, with symptoms representing a functional disturbance of the autonomic nervous system. Closely allied to these were vasovagal attacks, which were often mistaken for symptoms of grave organic disease. The hysteric was the classical simulator of many diseases, and to understand his symptoms a study of the patient as a whole was essential. The distinction of pseudo-fits from true epilepsy depended essentially upon this. Neglect of the psychological aspect frequently led to failure in diagnosis and treatment.

Dr. MAPOTHER complimented the openers on their practical treatment of the problem before them. The neurologist had taken a more definitely psychological view than the psychologist. Dr. Riddoch took the positive line in defining "functional" as synonymous with psychogenic. One main source of error that had not been previously mentioned was that mental symptoms of early and insidious organic diseases were related to the type of personality, and were often indistinguishable from functional conditions; in short, the man became more than ever himself. At the Maudsley many cases of early organic disease were seen that were too mentally ill for a neurological hospital and not mentally ill enough for certification. Even definitely hysterical symptoms might be a symptom of organic decontrol. The first requisite for right diagnosis was that a psychologist should be a competent neurologist. He was amazed that this had sometimes been denied.

Dr. A. GREIG ANDERSON (Aberdeen) agreed that it was difficult to give satisfactory definitions of organic and functional disease without introducing a cross classification. The psychosis seemed to be a disease of a different order from the psychoneurosis. He deprecated the use of the ambiguous term "borderland case," since it suggested a transition between two separate categories of disease. It was true, however, that in early stages of schizophrenia many hysterical symptoms might occur, though the individual was always schizophrenic from the start. Functional disease was a reversible process, at least in the early stages. Organic disease was, from the beginning, an irreversible one, though it might be arrested. The case which had presented definite organic signs would continue to do so at all subsequent examinations; whereas functional disorder varied widely from time to time. Functional disorder might last for life without giving organic signs. Organic disease had an orderly sequence of onset, development of physical signs, symptoms, and stages; this was not so in a functional case. He stressed the necessity for complete and careful history-taking, not only as to the patient's past diseases, but to his life as a whole—his emotional reactions to life.

Dr. HELEN BOYLE (Hove) said that the meaning of the term "functional" was not clearly focused. It would be agreed that all forms of activity of the nervous system must be associated with physical changes. It seemed as if prolonged dysfunction might lead to abnormal physical alterations in other parts of the body, even if not in the nervous system. The possibility of recovery was a salient point in the use of the word "functional"—that was to say, it implied that the case was amenable to treatment. This necessity for treatment was often overlooked and the case disregarded as though "functional" were synonymous with "malingering." Patients should be seen alone in order to obtain an individual approach, whatever the opposition of the family.

Dr. FERGUS R. FERGUSON (Manchester) preferred to speak of organic and non-organic disorder. The patient who was suffering severely from a functional disorder was often told that there was nothing wrong with her. This was obviously not true. Among the most difficult conditions to be differentiated were cerebral arteriosclerosis, myasthenia gravis, and brachial neuritis. The history of

THE SECTIONS: SUMMARY OF PROCEEDINGS

THE BRITISH
MEDICAL JOURNAL

transient attacks of numbness, weakness, and loss of vision was more important than the presence of abnormal physical signs in the diagnosis of disseminated sclerosis. In cerebral vascular disease insufficient attention was paid to psychological disturbances; this caused many grave errors. In contradistinction to Dr. Petrie's experience practically all his own cases of myasthenia gravis had come with the label "functional." Neuritis in less common situations such as brachial, external popliteal, anterior crural, or lumbo-sacral were frequently diagnosed as "purely functional," especially as an anxiety state as frequently superimposed.

Dr. R. D. GILLESPIE made four generalizations. First, all physical symptoms and signs that might be regarded as the direct effect of emotional disturbance were probably of psychological origin, if no relevant organic disease could be discovered. Secondly, symptoms or signs that followed concepts of disease rather than physiological patterns were probably of psychological origin. Thirdly, where physical signs occurred in conjunction with symptoms these signs of organic alteration should be relevant to the complaint. Fourthly, in regard to the history, important characteristics of a psychogenic history were its time relations to certain psychological factors. There was a group that stood midway between the purely psychogenic and the purely physiogenic—notably, asthma, and probably eczema and prurigo, Graves's disease, diabetes, and certain cases of rheumatoid arthritis.

Dr. E. DOUGLAS GRANGER (Bournemouth) gave the details of cases illustrating four difficult conditions: (1) Advanced chronic neurasthenia. (2) Psychogenic symptoms associated with anaemia. (One case had repeated vaso-vagal attacks and a severe degree of agranulocytosis from which she recovered.) (3) Excessive fatigability, found later to be associated with myasthenia gravis. (4) Cases suggesting involvement of the basal ganglia and extrapyramidal motor system. These appeared to be getting more common. Dr. AUBREY J. LEWIS drew attention to those organic cases in which at some stage of the illness the clinical picture satisfied every positive requirement for a diagnosis of functional disorder, and sometimes no physical signs of organic impairment were present. Where hysterical phenomena were present and sometimes an adequate motive for the symptom, there was also not infrequently a coarse topical lesion in the central nervous system. The explanation of the appearance of a functional syndrome in the course of organic disorders might be (1) that the patient had a personality which predisposed him to this type of symptom when provoked, either by psychic or physical damage; this was generally accepted, but did not always seem to be true; (2) that a physical change in the central nervous system had a psychic action in producing certain functional syndromes; or (3) the functional syndrome might be psychogenic, representing a reaction along comprehensible lines to the physical illness. Ignorance of neurology exposed the psychologist to innumerable blunders. Dr. A. T. WILLIAMS (Bordighera) said that functional disease should be positively diagnosed and not merely suggested by exclusion of organic factors. He quoted cases to illustrate this. The difficulty in diagnosis arose in cases where an organic lesion existed which was not in itself disabling, associated with the belief on the part of the patient that he was incapacitated by it. Dr. LIONEL WEATHERLY (Bournemouth) quoted two precepts which he had received from his father some seventy years ago: (1) The causation of almost all hysteria has been an abnormal love of sympathy; (2) if you would help the patient you must accept some pain or other as the cause of the symptoms. Dr. MURDO MACKENZIE said the differential diagnosis between neurological and psychogenic lesions was that bearing a subjective experience. Conversion symptoms of hysteria were the end-results of a subjective psychogenic process, while anxiety states and neurasthenia were objective neurological conditions. Conversion symptoms in hysteria were late, chronic, as a rule incurable, and really unimportant. Crude methods would remove these for a short time, a fact which had been given undue notoriety. In one sense they were in the same category as delusions. Dr. HAROLD SIMMONS (Bournemouth) emphasized the

importance, from the general practitioner's point of view, of the differential diagnosis, because of the difference in treatment in these types of illnesses. Dr. JAMES COLLIER referred the meeting to the methods of the ancient Greeks in the treatment of psychogenic physical symptoms. It was always well to beware of fits, since the most typically functional turned out to be organic occasionally. Dr. RIDDOCH, in summing up, said that it would be purely artificial to separate psychiatry from neurology. Dr. PETRIE, in his reply, welcomed the fact that neurologists and psychologists were much more appreciative of each other's point of view than formerly, a fact which was of happy augury for their patients.

OESTRUS-PRODUCING HORMONES

With the President, Professor J. W. BIGGER (Dublin), in the chair, Professor E. C. DODDS opened a discussion on oestrus-producing hormones. Professor Dodds said that it was now almost certain that the oestrus-producing hormones in the urine of pregnant women belonged to the group of sterols, and had in common a partially hydrogenated phenanthrene ring. Of the three hormones, trihydroxy-, ketohydroxy-, and dihydro-oestrin, the last was much the most powerful. In the so far unsuccessful attempt to synthesize ketohydroxy-oestrin a series of compounds had been prepared in the laboratory which could produce all the known phenomena of oestrus. It had also been shown that the naturally occurring oestrus-producing hormones were linked on one side with carcinogenic substances, and on the other with the vitamins and certain plant sterols. The specificity of these hormones was not restricted to any one group of animals; all female animals responded to injections of them if sufficient quantities were given. Kauffmann had shown that, provided sufficient of the hormone was given together with the corpus luteum hormone, it was possible to produce menstrual changes in the uterus, even in ovariectomized women. The menses could be induced in women suffering from primary or secondary amenorrhoea, and long after the menopause. In menopause cases very good results had been reported with doses of 50,000 mouse units injected twice each week, with alleviation of the psychic symptoms, and cure of the characteristic chronic vulval inflammations. Use of the corpus luteum hormone had resulted in the controlling of certain types of menorrhagia, and patients suffering from repeated abortions had been successfully brought to term.

Dr. A. S. PARKES said that the sexual cycles of all mammals had the same essential features—namely, a first phase characterized by growth and ovulation of the Graafian follicle, and a second by growth of the corpus luteum and by pregnancy if fertile mating had occurred. The oestrus-producing hormones were essentially associated with the first phase, as could be shown by the production of its ordinary manifestations by injecting hormones into ovariectomized animals—for example, in the mouse or rat the vagina underwent cornification, in vulval skin dilatation. In the baboon the perivulval function of the oestrogenic hormone was to sensitize the uterus to progesterin. In immature or ovariectomized animals, progesterin had no effect unless the uterus had previously been brought into the condition of oestrus by the action of oestrin. This interrelation between the two hormones might prove to be of clinical importance. Dr. H. GARDINER-HILL described his experience in treating eighteen cases with oestrin and luteo-hormone obtained from Professor Kauffmann, whose technique and dosage he had followed. Eleven cases of secondary amenorrhoea, of duration varying between one and thirteen years, had been treated with full doses of oestrin and luteo-hormone, and in all but one menstruation had occurred, its time of onset varying between thirty-six

and fifty-six hours after the end of the treatment. In several cases further courses of treatment had been given, always with positive results, but in no case was a regular menstrual cycle restored. Five cases of secondary amenorrhoea received oestrin alone, and three menstruated after an interval of seven to nine days. In one of these, menstruation occurred spontaneously in the following two months. As to the case of primary amenorrhoea which he had reported on at the Royal Society of Medicine in February, 1934, on Kauffmann's advice he had given two further courses of oestrin and luteo-hormone, after both of which menstruation had occurred, but there had been no spontaneous return of the cycle. The secondary sex characteristics had now developed markedly. Dr. Gardiner-Hill thought there was no doubt that these hormones, given in the way Kauffmann suggested, almost invariably produced menstruation in cases of amenorrhoea, but they did not seem to solve the problem of the regulation of the periodicity of the menstrual cycle.

Dr. J. M. ROSSON (Edinburgh) dealt with the effects of oestrin on the uterine muscle. He stated that the muscle showed variations in activity during the menstrual cycle, and that probably both its rhythmic contractions and its reactivity to the oxytocic hormone of the pituitary reached a maximum at the onset of menstruation. The reactivity to oxytocin also varied during pregnancy, and reached a maximum at parturition. Oestrin was concerned in these effects. This increased reactivity to oxytocin could also be produced late in pregnancy, and this raised the hope that it might be possible to control this stage in the human being. The dosage necessary to affect the human uterine muscle was not known, but the rapid destruction of oestrin in the body suggested that large doses at frequent intervals would be necessary.

Dr. P. M. F. BISHOP dealt with Markee's work on transplanting endometrium in the rabbit to the anterior chamber of the eye, which he had himself confirmed. The vascular changes in the transplants could be observed. Normally there was rhythmic blushing and blanching five or six times a minute. After an injection of oestrin the pink colour of the graft deepened within ten minutes, and vaso-dilatation arrested the rhythm within half an hour. The technique of grafting presented difficulties, but in a successfully grafted rabbit the urine of suspected pregnancy could be very rapidly tested for oestrin. The test was not so delicate as the Aschheim-Zondek one, and the earliest positive result obtained was forty-seven days after the last period.

Mr. L. C. RIVETT, as a gynaecologist, was interested in certain clinical conditions apparently due to oestrous-producing hormones: (1) infantilism causing amenorrhoea or dysmenorrhoea; and (2) the menopause, either spontaneous or surgical. Was it possible to demonstrate by a quantitative test a deficiency of oestrin? Was the excess in the urine in pregnancy due to over-production or to excretion of an unwanted hormone? It was accepted among endocrinologists that ovulation occurred in the human being fourteen to sixteen days after menstruation commenced. Yet on clinical grounds this was considered the "safe period." He suggested that the observed ovulation was the casting off of a spent ovum, and that fertile ovulation was produced, as in the rabbit, by the stimulus of coitus.

Dr. M. TAUSK (Holland) drew attention to the functions of oestrin in the male. It was present in urine and testes. Though it depressed the hormone production of the testes, it promoted the growth of the smooth muscle of the seminal vesicles and caused hyperplasia and metaplasia of prostatic epithelium. This effect could be counteracted by injection of male hormone. Possibly it played some part in the pathogenesis of enlarged prostate. Dr. Tausk also pleaded for uniformity in methods of standardization and in size of units, but doubted whether dosage by weight would be practicable for some time.

Professor D. CAMPBELL (Aberdeen) thought the oestrogenic action of anterior pituitary extracts should be considered. Such extracts in small doses caused a typical increase in uterine activity, as seen with oestrin; if continued, the corpus luteum effect of diminished activity was seen.

Professor DODDS, in reply, said he considered it impossible at present to estimate oestrin quantitatively in urine. He was in favour of expressing dosage of oestrin by weight rather than by biological units. He thought the general acceptance by all speakers of the possibility of causing menstruation by hormone injections showed how much progress had been made.

SECTION OF OPHTHALMOLOGY

Thursday, July 26th

BLINDNESS FOLLOWING N.A.B.

At the second meeting of the Section, with Mr. LESLIE PATON in the chair, Mr. F. A. JULER read a paper on a case of blindness following the administration of N.A.B. He said that cases of blindness following the pentavalent group of organic arsenic compounds had been well recognized in the past, and had led to the non-use of most of those compounds. Blindness after the trivalent or salvarsan group was very rare, few cases having been reported. He reported a case in a woman of 46 following a course of N.A.B. Six doses had been given, commencing with 0.3 gram and concluding with 0.9 gram twenty-eight days later. Fifteen days after the last injection the patient became rapidly blind in both eyes, losing all perception of light in one eye, and the vision being reduced to hand movements in the other. The disks became white, and the arteries narrow with white lines along them. Two years later the vision was still the same. She had previously had no trouble with her eyes, and there was no complaint of vision. She had no gross syphilitic lesion; it was suggested that the arsenic had affected the optic nerve or retinal vessels directly and that it was not a case of a "Herxheimer" reaction. Mr. A. D. GRIFFITH quoted six cases of patients blind from atoxyl in the early days of organic arsenic, and asked whether it was necessary to do elaborate liver function tests. Mr. D. HARDIE (Bournemouth) asked whether the arsenic was the cause of the damage and whether bismuth was safer. In reply, Mr. JULER stated that the accident was rare and that the cause was unknown.

ADVANCEMENT AND TENDON LENGTHENING

Opening the discussion on the technique of advancement and of tendon lengthening in strabismus operations, Mr. W. B. INGLIS POLLOCK (Glasgow) said that during the last eleven years he had been using a clove hitch to attach the stitch to the rectus muscle for advancement operations. Two stitches were employed. The advantage of this procedure was that the only knot for each stitch was outside the conjunctiva. The muscle did not require to be exposed for removal of the stitch because one cut brought the entire stitch out. In tendon lengthening he employed two hooks slipped through small openings in the conjunctiva, one above the tendon and the other below. The two hooks were then separated by 10 to 15 mm. Two cuts were made at one side of the tendon: one in front of the anterior hook and one behind the posterior. The intervening cut on the opposite side of the tendon was done between the two hooks; this procedure, being subconjunctival, did not require sutures, and the dressing was only applied for twenty-four hours to arrest haemorrhage. In the discussion, in which the President, Mr. F. W. LAW, Mr. BISHOP HARMAN, and Mr. F. A. JULER participated, the preoperative cutting of the lashes and the possibility of doing squint operations in the outpatient department were considered.

LOCAL ULTRA-VIOLET THERAPY IN EYE DISEASE

Mr. F. W. LAW, in a paper on local ultra-violet therapy in eye disease, gave a short description of the two types of apparatus used for local irradiation of the eye—that for the conjunctiva of the lids, and that for the cornea and episclera. He said that the apparatus at present available for the latter was far too expensive, and he had designed one which he hoped would be marketed at a price which any ophthalmic hospital could easily afford. After

referring to the dangers of ultra-violet irradiation, which he said had been greatly exaggerated, he himself never having seen a single case of ocular damage from this cause, he gave an account of the cases treated in his department at Moorfields during the last twelve months. From this it appeared that the most successful results to be expected from local therapy were in cases of recurrent erosion, corneal ulcer, some forms of keratitis, and epitheritis, and in sterilizing the conjunctival sac before operation. The President related a case in his experience of cataract due to ultra-violet irradiation. Mr. A. D. GRIFFITH asked whether it was necessary to fix the eye during exposure. Mr. LAW, in reply, stated that the possibility of other factors producing cataract, as in the President's case, had to be considered. Whether an eye required to be fixed or not depended on its irritability.

ORTHOPTIC TREATMENT: ITS SCOPE AND LIMITATION

In a paper on orthoptic treatment Miss M. A. PUGH said that orthoptic training had become a necessity owing to the failure of operative measures completely to correct squint. In some cases the eyes were straight immediately following operation, but relapsed soon after. This was to be expected where the subsequent formation of scar tissue might alter the position of the eye, and also where the patient had to deal with images which were disorientated in space according to his former habit of sight. The residual deviation after a squint operation often included a vertical displacement and/or a cyclophoria. These displacements, if left, did not correct themselves, but could usually be corrected by training. The age difficulty was generally overrated. Training was certainly more satisfactory in patients of 4 or 5. Nevertheless, adult patients could re-develop their fusion faculty easily; this was seen in patients who developed a divergent squint when the power of accommodation decreased. In her opinion the one serious limitation to orthoptic training was the eye which had been allowed to become amblyopic. Such an eye was best treated up to 7 years, but good results were obtained by occlusion up to 14 or more. Alternating squints gave as good results as monocular squints, but tended to take a longer time. The President asked whether Miss Pugh advocated squint training as a preliminary even in cases that would obviously come to operation. In reply to the discussion, in which Mr. GRAY CLEGG, Mr. P. A. ROSS (Bournemouth), and Mr. INGLIS POLLOCK joined, Miss PUGH said that training was always of value. It helped to avoid post-operative diplopia. She recommended the gradual occlusion of an eye—for example, using a varnished lens rather than an occluder.

PHYSICS AND OPHTHALMOLOGY

Mr. F. RIDLEY, reading a paper on physics in the problems of modern ophthalmology, showed graphs representing the distensibility of the globe, and described the experimental work upon which these were based. He discussed the physical laws relating to pressure in liquids, and, applying them to the problem of the intraocular pressure, showed that the latter was determined by the tension in the walls of the globe, and was equal to the pressure within any blood vessel in the eye less the pressure due to the support afforded by the vessel wall at the point observed. From the graphs the amount of blood normally present in the living eye, and the expansion of the vascular bed of the uvea, when active tone was lost, could be deduced. It was further shown that such expansion of the vascular bed could produce rises in intraocular pressure as great as any observed clinically. The graphs also demonstrated that the walls of the globe exhibit the phenomenon of stretching when submitted to distension as in glaucoma, and that glaucomatous eyes give such a "stretched" curve. The importance of this stretching in predisposing the eye to a second attack of glaucoma was emphasized.

DYSTROPHIES AND DEGENERATIONS OF THE MACULA

Mr. ARNOLD SORSBY, in a paper on the dystrophies and degenerations of the macula, drew a sharp distinction between these two groups of lesions. In the dystrophies,

he said, there was a hereditary basis, recessive, dominant, or irregularly dominant. The age of onset varied in different families, as did the ophthalmoscopic appearance, but within the same family the lesion had an almost photographic likeness in the members affected. Abiopathy was the underlying factor in these affections, which ranged from severe lesions present at birth or developing shortly afterwards (Best's disease), to pre-senile familial type of Tay's choroiditis. The group possibly included also some forms of so-called senile degeneration. In contrast to these dystrophies, which were sometimes associated with widespread neurological and skeletal lesions, the degenerations of the macula followed upon some clear degeneration of the macula. Mr. SORSBY drew attention to disciform degeneration of the macula with its kaleidoscopic range of intermediate appearances and characteristic terminal stage of disk-like atrophy at the macula. Referring to the cases of macular dystrophy associated with central nervous system manifestations, the President related adult cases of macular dystrophy associated with psychoses. Mr. G. CLEGG thought that the cases grouped under disciform degeneration helped to explain cases previously diagnosed as tuberculous. Mr. SORSBY, in reply, said that attempts to establish an entity of cerebro-macular affections occurring in later life had so far failed.

SECTION OF ORTHOPAEDICS

Thursday, July 26th

ADOLESCENT AND SENILE KYPHOSIS

With the President, Mr. HARRY PLATT, in the chair, a discussion on adolescent and senile kyphosis was opened by Mr. C. LAMBRINUDI. He confined his remarks to the adolescent condition, a rounded dorsal kyphosis of insidious onset, making its appearance between the ages of 12 and 17. There were, he said, five fairly well defined clinical groups. In the first, kyphosis appeared without pain or other symptoms in an otherwise healthy patient. In the second, the onset was similar but the child was tall, poorly developed, and had frequent debilitating illnesses. In the third group, the onset was fairly rapid, a history of trauma was common, and pain was a very definite feature—the condition first described by Scheuermann in 1921. Patients in the fourth group showed a kyphosis with evidence of endocrine imbalance; the child was usually too tall for his age, and the secondary sexual characteristics might be irregular. Lastly, adolescent kyphosis might develop rapidly after an acute chest infection, particularly pneumonia. The various aetiological factors were then discussed, and it was shown that infection, hernia of the nucleus pulposus, and repeated minor traumata had all to be taken into account. Mr. Lambrinudi had examined some 400 school children, and had found a definite association between adolescent kyphosis and tightness of the hamstrings. If a child with tight hamstrings was repeatedly compelled to perform toe-touching exercises, hyperflexion of the spine occurred, since the hamstrings could not be stretched by leverage applied through the spine.

Dr. JACQUES CALVÉ (Paris) described the formation of the long, ugly curves that appeared in the cervical and lumbar regions in an untreated case of adolescent kyphosis. A patient in whom the disease was allowed to run its natural course ended up with a camel-like hump in the dorsal region, with marked lordoses above and below; in consequence, the whole trunk and neck appeared to be shortened. The problem of treatment was exactly the same as the one that had to be faced in dealing with extensive dorsal caries. If short, compensatory curves could be induced immediately above and below the segment of the spine in which kyphotic changes had occurred, the total shortening of the trunk would be negligible, the cosmetic result excellent, and the patient would be spared the grinding backache so commonly found in severe lumbar lordosis. This result might be obtained by nursing the patient in a plaster bed, so con-

structed that the normal cervical and lumbar curves were obliterated and constant pressure was exerted on the spine immediately above and below the kyphos. The Minerva jacket with a posterior window over the kyphos worked in the same way, with the added advantage of making constant recumbency unnecessary. Pressure above and below the kyphos was made by insertion of pads of felt through the window in the back of the jacket.

Professor H. A. HARRIS said that although the spine at all ages accounted for 37 to 40 per cent. of the total body length, and the dorsal part at all ages accounted for 37 per cent. of the total spinal length, yet there was a marked disproportion in the growth of the cervical and lumbar regions, as regards both the bony vertebrae and the fibro-cartilaginous disks. The disproportion in growth in the case of the disks was more marked than that of the bony vertebrae, for the total height of the disks in the cervical and dorsal region was doubled between birth and adolescence, whereas in the lumbar region the disks increased fourfold. The primary and secondary centres of ossification in the vertebrae were illustrated radiographically, and special attention was directed to the postponement of consolidation in the spine and os innominatum of man in accord with the prolonged period of childhood and the delay of puberty. The growth processes in relation to the epiphyseal plates above and below the body of the vertebrae were shown to be identical with those at the growth cartilages of the long bones. The epiphyseal plates were to be regarded as a means of limiting growth in the spine, so that the range of variation in total spinal length could be maintained within much narrower limits than variation in stature. Radiographs were shown indicating that nutritional and infectious diseases, with or without certain underlying perversions of growth, had a place in the aetiology of adolescent kyphosis. Schmorl's useful demonstration of lesions of the fibro-cartilaginous disks did not appear to explain all cases. Professor Harris compared the changes in senile kyphosis to those reversions which are familiar in old age, both in the mandible and in the vault of the skull, whereby the bone is restored to its infantile condition. In childhood the disks were relatively immune and the vertebrae peculiarly susceptible to nutritional and infective conditions. In old age the vertebrae were susceptible to nutritional conditions such as osteoporosis or osteomalacia, and the disks and ligaments were peculiarly liable to calcification and ossification as a result of chronic infections such as pyorrhoea, leucorrhoea, and gonorrhoea.

Mr. N. ROSS SMITH (Bournemouth) said that Schmorl's theory of congenital weakness of the cartilaginous plates above and below the nucleus pulposus left several clinical facts unexplained. If the defect was present from birth, why was it that the onset of deformity was always delayed until puberty? Furthermore, nuclear herniae were conspicuously absent in many cases of marked adolescent kyphosis. There was little doubt that infection was of some aetiological importance. A case was described in which a tall youth of 18, with kyphosis of four years' duration, showed signs of low-grade chronic infection: slight fever, sweating, secondary anaemia, a polymorphonuclear leucocytosis, and an increased sedimentation rate. The tonsils were found to be grossly infected; after they had been removed the patient's condition rapidly improved. It was admitted that the chronic sepsis and the kyphosis might be quite unassociated, but there was no doubt that the bone changes had occurred during the time of the patient's ill-health. Mr. B. WHITCHURCH HOWELL espoused the infective theory, particularly in the senile cases. Many of his patients were so ill that their appearance suggested the presence of malignant disease. Evidence of chronic sepsis was by no means uncommon in adult kyphosis. He felt that the economic importance of the adolescent condition was insufficiently appreciated, and that claims for disability supposed to have arisen during the course of work were too frequently recognized, when in reality the trouble in the back dated from the appearance of a kyphosis during school life. The obvious remedy was early recognition of the condition at school orthopaedic clinics and the prompt institution of treatment. Miss MAUD F. FORRESTER-BROWN (Bath) supported Mr.

Lambrinudi's statements regarding the aetiological importance of tight hamstrings. In a certain physical training college she had traced numerous cases of sacro-iliac strain to the vigorous attempts of certain pupils to stretch their unstretchable tight hamstrings. She had found that in cases of established kyphosis it was difficult, often impossible, to treat patients in recumbency. Considerable relief of pain and the development of good compensatory curves often followed a course of abdominal exercises and the wearing of a light Goldthwait brace.

SECTION OF ANAESTHETICS

Thursday, July 26th

PRACTICAL DEMONSTRATIONS

The second meeting of the Section was devoted to demonstrations at the Cornelia and East Dorset Hospital, Poole. Dr. W. B. PRIMROSE (Glasgow) demonstrated closed anaesthesia with carbon dioxide absorption in a case of cholecystectomy. He used his single-phase apparatus anaesthetor "M.7." Dr. H. J. A. SIMMONS (Bournemouth) demonstrated the intravenous use of sodium evipan in four cases. Dr. J. C. A. NORMAN (Broadstone) showed two cases, one of appendicectomy and the other of implantation of radium around the uterus, in both of which spinocain was used. Premedication had been administered as follows: evening prior to operation, 3 grains luminal; one and a half hours before operation, 3 grains nembutal; half an hour before operation, 1/2 c.cm. omnopon-scopolamine; a quarter of an hour before operation, if the patient was not drowsy, a further 1/2 c.cm. of omnopon-scopolamine.

SECTION OF OTO-RHINO-LARYNGOLOGY

Thursday, July 26th

ALLERGIC FACTORS IN RHINORRHOEA

With the President, Mr. J. S. FRASER, in the chair, the discussion on allergic factors in rhinorrhoea and nasal catarrh was opened by Mr. T. H. JUST.

After defining the term "allergic disease," Mr. Just said that his remarks were restricted to allergy as seen by the rhinologist in a rather indefinite form, either complicated or uncomplicated by catarrh. He discussed the factors operating in vasomotor rhinitis and some of the causes, one of which, he maintained, was the use of face powder by the modern young woman, and particularly of powder which contained orris root as an ingredient. He dealt with the allergic's sensitivity to the staphylococcal protein as a cause of the vasomotor rhinitis, and the effects attendant on the administration of minute doses of autogenous vaccines in patients suffering from asthma and nasopharyngeal catarrh.

Mr. E. D. D. DAVIS said that from a clinical point of view cases of allergic vasomotor rhinorrhoea could be divided into two groups: (1) those in which there was no anatomical abnormality; and (2) those of long duration with consequent permanent oedema, polypi, etc. In all cases the allergic and general condition must be treated. Operative treatment in the majority was unsatisfactory, but when permanent changes such as polypi and suppuration supervened operation became a necessity. There was need for research into the basis of allergic rhinorrhoea, which might lead to the successful treatment of asthma and hay fever.

In the discussion which followed Mr. E. WATSON-WILLIAMS (Bristol) contended that the treatment employed depended on the degree of nasal abnormality. Where the rhinorrhoea was slight it might be sufficient to avoid exposure to the allergic factors. Where there was gross abnormality he advised very slight cauterization of the septal spur. Dr. W. C. DAVIDSON (Torquay) emphasized the importance of the gastro-intestinal factor in asthma and rhinorrhoea. Professor H. S. BRACKETT (Montreal) asked what was the influence of race on the disease. In his town it was particularly prevalent among the Jewish

SECTION OF PAEDIATRICS
Thursday, July 26th

OSTEOMYELITIS

With Dr. H. H. CHODAK GREGORY, Vice-President, in the chair, Professor JOHN FRASER (Edinburgh) opened a discussion on acute osteomyelitis.

He pointed out that, while staphylococcal osteomyelitis was apparently disappearing, there had been a definite increase in the last twelve months. He accepted the view that the bone disease arose from a blood stream infection, and to a certain extent the local pus formation might be regarded as a defensive mechanism, akin to a fixation abscess, a point of some importance in regard to infection. Dealing with the cause of the localization of the infection, Professor Fraser suggested that the great concentration of reticulo-endothelial tissue in the marrow of the growing bone might explain the occurrence of a localized reactive process in response to a generalized infection. Treatment, he said, was essentially conservative; he was an advocate of a form of the Starr technique. Actually he was accustomed to expose the affected area of bone, and then, by means of a drill one-eighth of an inch in diameter, perforate the cortex of the metaphysis in a number of places, covering as far as possible all the infected area. A special gauze dressing was then packed into the wound, and complete immobilization secured by encasing the limb in plaster so as to include the joints above and below the lesion. After a fortnight the plaster was removed, and a fresh plaster applied for a period of four to six weeks. In the treatment of the general condition Professor Fraser employed an anti-staphylococcal immuno-blood transfusion if the temperature had not fallen or shown signs of improvement by the third day after operation. Staphylococcal serum had been disappearing, and, apart from immuno-transfusion, he relied upon an abundant supply of fluid and a high vitamin intake.

Mr. H. TYRRELL-GRAY said that over a period of many years he had become more conservative in treatment, so that actually for the past five years he had not operated on a single case of osteomyelitis. He regarded the disorder as essentially a septicaemia, with the local lesion as an incident. He admitted that in desperate cases there was a great deal of anxiety for the surgeon who wished to hold rigidly to his principles, but he had found that treatment of the septicaemia, without any interference with the local lesion, gave good results. By close cooperation with the pathologists there had been evolved an intensive form of attack upon the general infection, mainly by means of intravenous injections of mercuric chloride (1/40 to 1/16 grain), and the use of anti-staphylococcal serum or anti-streptococcal serum, depending upon the organism found on blood culture. Secondary abscesses occurred and had to be dealt with; anorexia was a frequent symptom, but yielded to open-air treatment. This method, he said, avoided all the risks inherent in the opening up of the bone, the chances of pyaemia, and the chronic stages of sinuses and sequestra. Over a period of five years he had had one death, due to empyema developing comparatively late in the illness, and no instance of sequestration.

Mr. H. W. S. WRIGHT emphasized that little was known about the early stages of the malady called osteomyelitis, and it was obvious that the local bone condition was but the last act in a play. He thought more emphasis should be laid on the factors of poverty, overcrowding, dirt, and underfeeding in the lowering of resistance. As with rickets and bone tuberculosis, osteomyelitis would be abolished if enough people were willing to take enough trouble. Dealing with his personal experience, Mr. Wright emphasized the danger of leaving plasters on too long, and the value of the Carrel-Dakin methods in clearing up a persisting state of local sepsis.

Dr. L. COLE (Cambridge), speaking as a physician, thought that the early stages of obscure osteomyelitis were more likely to come under medical than surgical observation. In any case of acute unexplained pyrexia, although local signs were slight or negligible, the possi-

TONSILLECTOMY IN CHILDREN

Dr. B. ELIZABETH NESBITT (Edinburgh) opened the discussion on post-operative complications and results of tonsil and adenoid operations in children. Her material was based on 1,457 cases from Dr. J. S. Fraser's department at the Royal Infirmary, Edinburgh, and on 900 cases operated upon in private by Dr. Fraser. A statistical survey of all possible complications was carried out, and the results were carefully noted. The local symptoms for which the operation was recommended were completely cured in 75 per cent., partly cured in 18 per cent., and persistent in 7 per cent. of cases. There was a marked improvement in general health in 86.4 per cent., and no improvement in 12.2 per cent. The post-operative complications were higher in the hospital than in the private cases.

Mr. E. B. WAGGETT stated that the children who were sent home from hospital on the day of the operation did much better than those who were kept at hospital for twenty-four or forty-eight hours. Mr. T. RITCHIE RODGER agreed with Mr. Waggett on this point. Professor H. S. BIRKETT (Montreal) discussed the particular techniques in tonsillectomy which gave the best aesthetic results. He had never had a case of pneumonia following a tonsil operation in children.

INFECTIONS OF THE MAXILLARY SINUS

Dr. I. B. THORBURN (Glasgow) opened the discussion on infections of the maxillary sinus. He reviewed the results obtained in 508 cases treated by Dr. J. S. Fraser at the Edinburgh Royal Infirmary from 1921 to 1930. Treatment was by conservative methods, and, where these failed, by the intranasal rather than by the radical operation. In the acute cases an ultimate cure was obtained in 50 per cent. by conservative treatment, and in 75 per cent. by intranasal operation. Conservative treatment, he said, was of little value in chronic cases; by intranasal operation one-third were cured and another third improved. The radical operation had special indications; in uncomplicated cases 60 per cent. were cured and in complicated cases only 25 per cent. The mucosa of the maxillary sinus was frequently polypoid, and this often accounted for the recurrence of nasal polypi after operation.

Mr. TILLEY said that in most cases of "choanal polypus" the antrum, on being opened, was found to be full of polypi. In his opinion, therefore, Dr. Thorburn was not justified in excluding these cases in his analysis of sinusitis. He further stated that the transillumination test was unreliable because one or two previous attacks of sinusitis would cause the affected antrum to appear more opaque for a relatively long time. Mr. WAGGETT deplored that the Lichtwitz trocar and cannula for washing out the antrum was still in use. Far better results were obtained and fewer antral operations would be required if Killian's needle were employed or that of Watson-

bility of acute osteomyelitis should be kept in mind. Even if the local lesion was becoming severe the manifestations might be slight, and it was necessary to make a minute examination of bones and joints, especially if there was any history of an injury. Accessory aids to diagnosis included a four-hourly temperature chart, leucocyte count, blood culture, and aspiration of fluid in the region of the local affection.

Mr. S. A. S. MALKIN (Nottingham) said that the problem of treatment in osteomyelitis had two aspects—the preservation of life, and, later, the preservation of function. He saw the chronic stages of the disease in an orthopaedic hospital, and as a result of this he concluded that early treatment should aim at promoting free drainage of the medulla with as little damage as possible; once the acute stage was over many cases could have their illness cut short by radical sequestrectomy. Mr. W. ARCH. MEIN (Bournemouth) raised one problem of aetiology—namely, the possible relation of the increased incidence of removal of tonsils by dissection with the occurrence one or two years later of osteomyelitis. The presence of intense oedema of the bone marrow was responsible for necrosis of bone, and treatment must be directed towards remedying this. Hence he sought to secure free drainage, with the use of an irrigation method to keep the openings in the bone and secure a free flow of purulent material. Dr. F. J. POYTON, the President, said that he had been brought up in the school which taught that if acute osteomyelitis was diagnosed there must be immediate operation to save life. After hearing the discussion he was very doubtful as to what he should do if a relative were affected with this disorder. He mentioned one difficulty in differential diagnosis—for example, in cases of acute lymphatic leukaemia with some infiltration of the bone in the neighbourhood of the joints. Mr. R. KENNON (Liverpool) held that if pus was present then operation had to be performed. It was important to realize the exact points where tenderness over the bones was to be expected. He was against prolonged covering-up of cases of osteomyelitis after operation. Mr. W. J. EASTWOOD (Liverpool) still thought, despite all he had heard, that the ideal operation was "guttering." He considered that exact diagnosis as to the extent of the disease and the operation should both be carefully planned in the ward as a result of clinical findings.

SECTION OF PUBLIC HEALTH (INCLUDING TUBERCULOSIS)

Thursday, July 26th

IMMUNIZATION IN THE SPECIFIC FEVERS

With the President, Dr. T. CARNWATH, in the chair, Dr. R. A. O'BRIEN (Beckenham) opened a discussion on immunization in the prevention of the specific fevers.

Dealing first with diphtheria, Dr. O'Brien said that such mixtures as toxin-antitoxin were being given up, but toxoid-antitoxin floccules (T.A.F.) were still popular. Toxoid alone was being more freely employed, sometimes combined with an immobilizing agent such as alum. The antigen alum-toxoid had proved remarkably useful in animal immunization in the laboratory, but it was doubtful whether it would displace formal-toxoid in two well-spaced doses for human immunization. When the chemist could prepare pure crystalline toxin as he now produced ferments and vitamins, more rapid progress could be expected, but the "pseudo" constituent which caused local swelling and general malaise would have to be eliminated. In dealing with an institutional epidemic, the dictum of 1923 still held good—"Schick-test and swab every inmate; immunize immediately the Schick-positive children, and isolate and examine daily the Schick-positive and swab-positive children, for it was in this group that all the cases of diphtheria appeared." It was as yet uncertain whether current methods of immunization would secure immunity against all types of diphtheria, but it appeared the best policy at present to endeavour to improve the type of prophylactic hitherto derived from the

Park 8 strain. There seemed to be no evidence that the morbidity or mortality rose even temporarily in a partly immunized community because of the suggested rise in the carrier rate among the inoculated. In scarlet fever, active immunization with a small series of doses of toxin gave high protection. The reduction of the number of injections had not yet proved practicable. Formalinization must not be carried too far; unless approximately 500 skin test doses of toxin per c.cm. were left, high immunity was not secured, even with three doses and the addition of alum. As regards whooping-cough, the vaccinating work of Madsen in Scandinavia and of Sauer and others in the United States offered considerable hope. Jundell in Sweden was endeavouring to obtain an equivalent of the valuable convalescent measles serum for the protection of young children in contact with whooping-cough patients.

Surgeon Captain S. F. DUDLEY, R.N. (Chatham), said that 10 per cent. of Greenwich Hospital schoolboys had lost their negative Schick reaction within two years of successful immunization. The immunizability of such cases had been permanently augmented, and, if later infected with diphtheria, antitoxin would be manufactured so rapidly that disease would not develop, apart from trivial sore throats. He wholeheartedly endorsed Dr. Nash's insistence on a post-inoculation-Schick test. Artificial protection against clinical diphtheria was no protection against carrier infection; it might even increase the risk of infection to unprotected members of the community. Every effort should be made, therefore, to protect the younger age groups or pre-school children, who were more liable than others to severe and fatal infection. The Greenwich School had been invaded in 1932 by diphtheria bacilli of the gravis type, indistinguishable from that which had caused such havoc at Leeds. No fewer than 146 healthy carriers had been detected, but had not been segregated since all the school had been previously immunized. There were no cases of clinical diphtheria, and only eighteen cases of mild sore throat with K.L.B. infection—a splendid testimonial to the value of artificial immunization, which could certainly reduce the morbidity of clinical diphtheria to a negligible figure.

Dr. WILSON SMITH insisted that any satisfactory method of immunization must be absolutely safe, cause no disturbance of health, be painless, and produce a high grade of long-lasting immunity. Such ideals had not yet been realized in the case of virus diseases. Viruses were so minute that the administration of an adequate bulk to immunize might be impossible. No susceptible animal species had yet been discovered, and so supplies in quantity of virus and immune sera could not be forthcoming. Yet great advances had been made. Immunization with killed or inactivated virus gave rise to a mild temporary result, which rendered possible the administration of doses of living virus which might otherwise have been lethal. Formalized and carbolyzed vaccines, useful in dog distemper, cattle plague, and human rabies, had proved unconvincing in yellow fever, and their immunizing properties quickly disappeared. Yet killed viruses had antigenic properties, and improved methods of obtaining concentrated virus, freed from the undesirable animal tissues, might lead to their extended use in the future. Living virus could be used with safety if modified by passage through animals, or associated with a protective immune serum. Yellow fever virus could be transmitted to mice by intracerebral inoculation, and carried on indefinitely thus from brain to brain. The final virus no longer produced a fatal infection in monkeys when inoculated subcutaneously or intraperitoneally, but only when introduced into the central nervous system. The milder non-fatal infection induced a solid immunity against all strains of the virus, and had been used for human beings, although often with the protection of a serum. A very careful balance of virus and serum was necessary. By using the intradermal approach smaller doses of convalescent serum were required; the crucial test would be furnished by the occurrence of an epidemic, but laboratory infections had already been obviated by this means. Although no serum was effective in measles, if

given after the onset of symptoms, prevention was obtainable. A similar use of convalescent serum would probably yield good results in poliomyelitis, chicken-pox, and mumps.

Dr. E. H. R. HARRIES discussed the indications for immunization, active and passive, in the practice of the fever hospital. In his experience, when in Birmingham, the procedure of seeking parental consent to produce active immunity to diphtheria during the stay of scarlet fever patients in hospital had, on the whole, worked satisfactorily, and resulted in the protection of large numbers of children annually. Benson had used toxoid in Edinburgh, and in 1933 inoculated about 1,000 scarlet fever patients under 10 years old, the parental consent rate exceeding 80 per cent. Apart from this practice the chief indications at present for active immunization were the protection of the hospital staff against small-pox, diphtheria, scarlet fever, and the enteric group. In his own hospital, in spite of abundant opportunities for infection, there was no evidence that the active immunization of nurses with toxoid was not proof against infections with gravis or intermediate strains of *C. diphtheriae*. The Dick test, carried out with a well-tested toxin, was a reliable indication of immunity to the toxin of the haemolytic streptococcus at the time the test was read. He had found that natural Dick-immunes possessed solid immunity.

Artificial Dick-immunes occasionally lapsed to an extent which permitted not only a positive Dick test, but a clinical attack of scarlet fever. If this was so in the case of nurses constantly receiving stimuli from the ubiquitous haemolytic streptococcus it was difficult to advise active immunization against scarlet fever in public schools. An outbreak of scarlet fever among lapsed artificial immunes might require considerable explanation. The positive Dick reactor was in a majority among public school communities. Advance in active immunization against scarlet fever still awaited a laboratory method of titration of the toxin and the determination of the optimum series of doses for the production of lasting immunity. The speaker produced figures to show that active immunization of nurses against scarlet fever did not increase the incidence of streptococcal tonsillitis among them. Prophylactic passive immunization against diphtheria, scarlet fever, and measles was of proved value in fever and in children's hospital practice, and Dr. Harries advocated the injection of a combined prophylactic dose of scarlet fever and diphtheria antitoxins in concentrated serum before tonsillectomy in clinics. During the recent measles epidemic in London he had, by the injection on admission of this combined prophylactic, succeeded in keeping his measles wards virtually clear from cross-infection with diphtheria and scarlet fever. Analysis of a consecutive series of 943 cases injected with the combined prophylactic showed a complete absence of anaphylactic shock and an incidence of late serum rashes in 89 (9.4 per cent.). Passive immunization of children exposed to measles could be successfully carried out, especially if or adult-immune serum. Dr. Harries discussed the question of dosage, and gave it as his opinion that recent work in the vaccine prophylaxis of whooping-cough promised well.

Dr. C. W. HURT said that the cost of immunization was far less than that of the nursing and treatment of cases. The process was almost painless, and in children reactions were rare. In the U.S.A. and Canada diphtheria immunization was an ordinary event in a child's life, and Canadians considered us very backward in this respect. In Birmingham, however, 70,000 children had been immunized; in Manchester, 20,000; and in Cork 10,000. In England and Wales diphtheria immunization was now in progress in 159 sanitary districts, and at least forty clinics had been established for this purpose. Not one person in the British Isles had died as the result of diphtheria immunization; for this thanks were chiefly due to Dr. O'Brien. If immunization was to make headway, the interest of the general practitioner must be secured; he was wanted to urge parents to have their children immunized, or to do it himself. General practi-

tioner schemes were in existence in two or three metropolitan boroughs; a scheme had been put forward by Kensington, Hammersmith, and Paddington practitioners, and another scheme was being operated for a rural area. Dr. Hutt suggested that authoritative information and advice should be issued to medical practitioners by a representative committee under the aegis of the British Medical Association, or actually by a committee of the Association comparable with those which had done such good work in connexion with mental deficiency and psycho-analysis.

Dr. E. H. T. NASH (M.O.H., Isleworth) thought that too many were under the deplorable delusion that a child once immunized would always be immune. Many children required six doses for immunization. He was actively engaged in a five years' campaign, the results of which, he thought, would be the establishment of public confidence. In 5,000 cases of full immunization, in which both a preliminary and a final Schick test had been made, he had not had a single case of diphtheria. Too many authorities were only giving three doses, and without Schick testing—a thoroughly unscientific procedure. Immunization was easier in a circumscribed community; in the general population immunization against measles was at present almost impossible, but the position was improving. Dr. J. B. HOWELL (M.O.H., Hammersmith) had inaugurated a campaign against diphtheria two years ago in the middle of a severe epidemic. It had proved very effective, and was being continued. Three immunizations were being given each term to children in infant schools. Dr. D. S. SUTHERLAND (Manchester) said that recently all cases entering fever hospitals had been immunized against diphtheria, and he was entirely in favour of it. Only three had returned subsequently with diphtheria, but one of the cases had proved fatal. A severe type of diphtheria had recently been prevalent in Leeds and Manchester. It was difficult to diagnose, resembling quinsy. One case had proved fatal, diphtheria bacilli only having been found on culture, and anitoxin having been given too late. The President, referring to a complaint by Dr. O'Brien of the lack of clinical material, thought that this was due to the country's democratic temperament. It was necessary to proceed cautiously and to ensure that the technique was perfect. It had been claimed that the fall in diphtheria mortality in New York had been due to wholesale immunization, but during the same period there had been a corresponding fall in London without this. Yet it would be criminal not to do everything possible to protect circumscribed communities, although the possibility of wholesale immunization was still lacking. No extravagant claims should be made, since they retarded progress.

Dr. O'BRIEN, replying, retorted that the United States claimed to be a democratic community. One great hindrance had been the use of the word "compulsory," an unfortunate echo of the days of compulsory vaccination. There were no absolute Schick negative and positive levels, but a host of intermediate stages best represented as a curve, which tended to fall in all cases from the negative towards the positive as time went on. Most immunized cases remained potentially immune, and only a few reached the Schick-positive level. There was no evidence that the antigen used at present was not operative against all types of diphtheria. Great progress had been made in virus information. The speaker had been agreeably surprised at the abundance of measles serum obtained by enthusiastic medical officers of health and various organizations, but there was not nearly enough yet.

MODERN SANATORIUM TREATMENT

In an independent paper, Dr. A. S. McNALTY said that the present tendency to regard artificial pneumothorax treatment as the main remedy for pulmonary tuberculosis had adversely affected the progress and improvement of ordinary sanatorium treatment. He outlined the various grades of treatment, and referred to the possibilities of segregation available. He suggested that alternation between hospital and sanatorium treatment was most desirable, and should be made possible within the limits

of a single institution. The principles of modern sanatorium treatment comprised: (1) early diagnosis; (2) proper selection of patients for such treatment; (3) full co-ordination between the tuberculosis officer and the sanatorium medical superintendent; (4) observation and hospital treatment, including collapse therapy; (5) correct co-ordination of hospital and sanatorium treatment; (6) study and treatment of each patient by the sanatorium medical superintendent; (7) proper sanatorium regime; (8) prolonged stay in the sanatorium; and (9) maintenance of the ex-sanatorium patient under medical supervision for at least five years. If these conditions were maintained less would be heard about the failure of sanatorium treatment.

In the ensuing discussion Dr. COATES said that sanatorium treatment had not had a full and fair trial. The war had interrupted the start of the scheme. There had been too much undue enthusiasm for it as well as for other lines of tuberculosis therapy. It had even been expected to cure cases in three months. Hopeless cases had been sent in to sanatoria. Dr. CHANDLER added that sanatorium treatment was now being improved. Collapse therapy was excellent, but tried too frequently.

SECTION OF RADIOLOGY AND ELECTRO-THERAPEUTICS

Thursday, July 26th

RADIOLOGY AND THE GENERAL PRACTITIONER

With Dr. D. D. MALPAS in the chair, Dr. J. H. DOUGLAS WEBSTER, President, opened the discussion on the value of radiology as an aid to the general practitioner.

Radiologists, Dr. Webster said, should be physicians practising radiology and not merely technicians. Radiology had produced more pathognomonic signs than centuries of medical observation. Köhler had said that radiological signs must always be secondary to clinical findings, but Holzknecht, with whom the speaker agreed, asserted that the reverse was often the case. Careful distinction must be made between good and bad radiology. Haenisch of Hamburg had said that there could be no "minor" radiology in the sense that there was "minor" surgery, but he (the speaker) doubted this. The lay practice of radiology should be made illegal, and recent legislation in Germany had been introduced to ensure this. Many people argued that the special instruction of students in radiology was unnecessary, but he disagreed with this. The claims of radiology should be brought more prominently before the medical profession and the public; this was being attempted in America and Sweden.

Dr. E. KAYE LE FLEMING (Wimborne) said that, from the general practitioner's point of view, radiology had made enormous strides since he was a student. The lack of personal contact between doctor and radiologist was a great loss to both, and written reports did not serve the same useful purpose as consultations. That all suspected bone injuries should be subjected to x-ray examination was a maxim not easy to live up to, mainly because of expense. He knew, however, that radiologists would be against any suggestion that screening alone was sufficient in such cases. He had never felt that there was urgent need for alteration in the laws regarding sterilization, and he would like to know whether the effect of x-ray treatment could be guaranteed. He hoped that radium would prove an alternative to the knife in carcinoma of the breast.

Dr. F. G. WOOD presented an analysis of 678 cases sent to him for radiological investigation. More than half were of fractures; next in order came cases requiring examination of the chest, joints, teeth, and urinary tract, and, finally, the barium-meal examination. Radiology was invaluable in lung and heart conditions, and had even been responsible for the discovery of previously unsuspected diseases, such as early pneumonia following influenza. Lipiodol had revolutionized the radiography of the chest, and in pregnancy it could show clearly the relation between the size of the foetal head and the

pelvis. General practitioners could help radiologists by enabling them to follow up cases.

Dr. H. GUY DAIN (Birmingham) hoped that the perfection of modern radiological technique would not tend to make clinical acumen unnecessary. Radiology was a valuable aid to diagnosis, but was sometimes unreliable. It was a great help to the general practitioner in cases of suspected fracture, but the legal aspect was, he thought, often over-emphasized. X-ray examinations helped in the control of cases of arthritis and tuberculous joints, and saved many good teeth from unnecessary extraction. It was most valuable, perhaps, in conditions of the gall-bladder and urinary tract. It was important to have a radiological opinion on which one could rely. With regard to treatment, Dr. Dain had found x-rays of great assistance in ringworm and other skin diseases, but he was not impressed with the results in exophthalmic goitre. He doubted the value of repeated x-ray treatment after radical mastectomy for carcinoma of the breast, and thought that the general practitioner was, on the whole, more impressed by the diagnostic than by the therapeutic side.

Dr. W. B. PROWSE (Brighton) said that the future of radiology was largely in the hands of the general practitioner, who could educate the public concerning it. Unqualified practice should not be allowed, and doctors and patients should realize that the radiologist was a physician and not merely a technician. The x-ray "picture" loomed so large that the public was apt to forget that great skill was required in its interpretation. Dr. Le Fleming had stressed the financial difficulties, but he thought that radiologists were as accommodating as other specialists in this respect. The fees were not high when the time and expenses of the radiologist were considered. Co-operation among radiologists, and between them and the general practitioner, was even more necessary in therapy than in diagnosis.

Dr. A. BAXTER (Alderley Edge) considered that few doctors had time to keep pace with advances in specialties such as radiology, and it was necessary for the practitioner to co-operate closely with the radiologist. In cases of hyperthyroidism in which operation was contra-indicated he had found x-ray treatment valuable. In advanced carcinoma of the breast it often saved the patient the misery of fungation through the skin. Radiological treatment was the method of choice in sterilization and in production of an artificial menopause.

Dr. G. B. BATTEN stated that, after forty-eight years as a general practitioner, he had come to the conclusion that good films were of no use unless interpretation by a highly experienced person could be secured. The late Dr. Stanley Melville had insisted on the value of attending post-mortem examinations on cases which had passed through the hands of the radiologist, and he concurred in this. He did not agree that students should be taught details of radiological technique; the result would be that they would regard themselves as radiologists when they had had no experience at all. The general practitioner should be told more clearly what radiology could do.

Mr. D. H. KIRCHIN (Barrister-at-Law) said that a doctor defending an action for negligent treatment of a fracture had little chance of succeeding unless he could show the jury an x-ray picture of the injured part or else written instructions from the patient that he did not wish an x-ray examination to be made. This state of affairs was, he said, an expression of the idea suggested by a previous speaker, that the x-ray film was a picture of the disease. Nevertheless, Dr. Dain had himself suggested, by implication, that this attitude was not altogether unreasonable, in pointing out that many fractures were easily mistaken for sprains. Although a doctor might treat these conditions with equal care, yet if he had to admit that he had confused them the jury might not believe that he had done his best if he had not had the injury radiographed. Now that such cases were being more frequently tried by a judge alone, under the New Procedure, the necessity for a radiogram might not be so urgent, as a judge had more appreciation of the true function of radiology.

Dr. J. F. BRULSFORD (Birmingham) maintained that students should be instructed about radiographic appearances. He had no objection to the unqualified radio-

POPULAR LECTURE: FOODS, FADS,
AND FASHIONS

The Popular Lecture in connexion with the Annual Meeting was given on July 27th at the Municipal College, Bournemouth, by Professor V. H. MOTTRAM, professor of physiology in the University of London, whose subject was "Food, Fads, and Fashions." Mr. H. S. SOUTTAR, Chairman of the Representative Body, presided over a crowded audience.

Professor Mottram quoted from Stefansson's *The Friendly Arctic*: "There is no field of human thought where sentiment and prejudice take the place of sound knowledge and logical thinking so completely as in dietetics." The arboreal ancestors of the human race at some period descended from the trees and took to the land, and then discovered that, in addition to insects and lizards, and perhaps small birds, the larger animals were worth eating. The first age of man was that of a hunter, living on an entirely meat diet. At a later stage he discovered that he could tame animals, like the goat and cow, and live on the milk or on the cheese made from the milk. Finally he took to agriculture, and consumed cereals and vegetables. He survived these tremendous changes, though probably with difficulty. The lecturer wondered whether the medicine men in those distant ages noted any increase in caries when man began on a cereal diet. When the Romans invaded Ancient Britain they brought their food fashions with them. What was the reaction of the natives? Did they, in A.D. 134, cr little to the east of the Isle of Wight and Hampshire, the Belgae from the Isle of Purbeck, to which came the Durotriges from Dorset, the Iceni from East Anglia, the Cantii from Kent and Sussex, even the Picts and Scots from the North, and invite a person interested in dietetics to tell them that all these food fashions did not matter?

DIETETIC HISTORY

That was conjecture, but in historic times food fashions had been changing in the strangest way. There was a delightful picture in the *Canterbury Tales* of a poor person's diet—the widow in the Priest's Tale, who practised simple diet, exercise, and a contented mind. She drank neither red nor white wine, her food was mainly black and white bread, broiled bacon, and an egg or two. Did she in the late spring ever have incipient scurvy? Probably not, for she took plenty of unpasteurized milk. (The lecturer hastened to add that he was not against the pasteurization of milk, but strongly in favour of it in present conditions.)

Some people sighed for the great days of Elizabeth. No one would want to live in her day if he understood what they had to eat. Sugar then, at present prices, cost a sovereign a pound, and only people like the Queen herself could afford it. Too much sugar was said to have caused the blackness of her teeth. Potatoes in those days were a curiosity. Ambassador Page said that the English had many vegetables, most of them cabbage. In those days cabbage was newly introduced, as was the French bean. The plum, cherry, and quince were new importations. There was no coffee, tea, or cocoa. Beer or, if one was better off, wine was drunk for breakfast. Beer-drinking at breakfast, according to a recent newspaper correspondence, continued until the seventies of the last century in Oxford, that home of lost causes.

In one's own time, Professor Mottram continued, diet had undergone many changes. In his own boyhood the tomato was just beginning to make its way; the banana had hardly appeared; grape fruit, now familiar on the breakfast table, came in about 1900. Before the war a certain commodity was only discoverable in German shops, but now every shop which supplied pig products furnished the liver sausage—he was sometimes inclined to think it was the only good thing which had come out of the war. Frozen mutton and chilled beef had come in since

grapher as long as it was realized that interpretation of the film was the most important thing. Fees could only be reduced by making less thorough examinations, and he was against contract work for this reason. He thought that clinical investigation was being neglected. Nevertheless the general practitioner could not afford to ignore positive radiological findings, even if clinical evidence was wanting. Dr. ROY WARD claimed that early diagnosis was the most important single factor in the treatment of malignant disease, and here the radiologist was in the hands of the general practitioner. Radium was advantageous in the treatment of menorrhagia, in that it was as certain as x rays, and the administration of an anaesthetic made thorough examination possible. Although radium was invaluable in inoperable cases of carcinoma of the breast, the position with regard to operable cases was not yet certain. Radium certainly relieved surgeons from the responsibility of performing useless operations in hopeless cases. Dr. C. H. C. DALTON (Ipswich) considered that education of the student as to what could be done by radiology should be thorough, and that every radiological specialist should spend a year in general practice before specializing. Dr. KIRCHIN disagreed with Dr. Dain that the treatment of a sprain and of a fracture without displacement was the same. An x-ray picture should always be taken, and the legal aspect of the problem was very important. He suggested the use of paper films as a means of reducing expense. Dr. S. L. MUCKLOW (Cheltenham) said that he always encouraged the practitioner to see the film with him, and there was, he thought, need for such co-operation. He had found x-ray treatment admirable for warts on the feet and hands. Dr. LE FLEMING pointed out the difficulties of adding further courses of instruction to an already full medical curriculum. He thought all specialists should have had experience of general practice. In pulmonary tuberculosis not only was radiological examination invaluable, but patients would often not submit to treatment without it. He had little faith in the radiological diagnosis of appendicitis, but films were useful in persuading patients to undergo appendicectomy. Dr. DOUGLAS WEBSTER, in reply, expressed the Section's indebtedness to Dr. Le Fleming for his paper. He thought that reliance on screening alone in fracture cases was dangerous. There was no risk of skin burns in the modern x-ray treatment of exophthalmic goitre. He had treated 200 cases without having this complication, and had recently treated several patients by daily applications for a week in order to shorten the treatment period. He agreed with Dr. Roy Ward about the importance of early diagnosis in malignant disease. In New York many insurance companies reduced premiums if the insured person consented to bi-annual examination. Some early cases must be discovered by this means. X rays were better than radon seeds in the treatment of extensive carcinoma of the breast.

The Section of Radiology and Electrotherapeutics held a demonstration on every afternoon of the meeting, in which slides were shown of cases in further illustration of the subject-matter of the morning discussion. The demonstration of these cases was followed by much interesting and valuable informal discussion. The following is a list of the subjects and demonstrators: Practical electrotherapeutics, Dr. W. J. Turrell, Oxford; genito-urinary cases, Dr. Dalton, Ipswich; cases of general interest where diagnosis has proved difficult, Dr. B. Grellier, Hastings, and Dr. D. Webster, London (the latter demonstrating cases of Dr. F. G. Nicholas); stomach and duodenal cases, Dr. Craig Mooney, Plymouth, Dr. Beatrice Collins, Richmond, Dr. C. H. Dalton, Ipswich, Dr. D. Webster (for Dr. F. G. Nicholas), and Dr. Payne, Leicester. Special mention must be made of Dr. Turrell's ingenious device for the regulation of current; of Dr. Dalton's cases showing the power of recovery of a kidney after the removal of calculi; of Dr. Nicholas's case of Cooley's anaemia, never before shown in this country; and of Dr. Grellier's case of cutaneous xanthoma showing changes in the vertebral column.

the childhood of many of those present, as had canned foods, the canning industry starting about 1870. These changes were partly due to better and quicker transport, but also to standardization of food products. Butter, for example, was made in larger and larger factories. The cream from which it was made was soured always with the same type of bacteria, and so the taste was standardized. People who had been accustomed to New Zealand butter and were suddenly switched over to Dorset said that they did not like the flavour.

A great refinement of food had taken place, particularly in sugar and flour; the former was now practically 100 per cent. pure. A great deal of food sophistication had arisen. In a physico-psychological laboratory, when an apparatus for matching colours was desired, resort was made to a tintometer used by the brewers to ensure that a particular brand of beer was always of the same colour. Even the best jam, with the exception of the products of one or two makers, was very sophisticated, containing a good deal of glucose, and a good deal of fruit juice which was not from the fruit after which the jam was named. He wondered whether, as a result of standardization, discrimination in food was being lost.

MODERN FOOD HABITS

Some curious mixtures of food were often consumed. In the States he saw a person eating sausages with waffles and golden syrup, and in Germany gooseberry jam with stewed beef, though people who had red currant jelly with their mutton had no right to make a remark, any more than the Englishman who favoured putrid cheese should express disgust at the diet of the Eskimo, which was largely putrid meat. Such cheese, by the way, had now largely disappeared from country inns, and was found only in West End clubs. The order and times of meals had also changed. At the coronation feast of William IV, for example, the courses, which had no particular order, began early in the afternoon, and went on for most of the remainder of the day. Afternoon tea was a modern innovation. From the biography of Fanny Kemble it appeared to have arisen about the 'fifties or 'sixties, when, under whispers of secrecy, tea was served in the lady's boudoir. The custom was now making its way with the French.

Practically every change of fashion had its reaction. There were always people who said that a new introduction was producing some horrible disease. Cancer had been ascribed to bread made from white flour, also to tomatoes, for no better reason than that since the introduction of tomatoes the cancer rate had gone up. He sympathized with the moral objection of the vegetarian to meat, though a psycho-analyst friend assured him that vegetarianism was due to the repression of cannibalistic desire. But meat was attacked on other grounds, as causing cancer, although in Australia, where they ate three times as much meat as we did, cancer was less prevalent than here. A new attitude of mind was that foods should not be mixed. "Quida," a novelist of some vogue in Victorian times, pointed out that animals never mixed their foods. Nor did they, but if their foods were mixed for them, he had never seen an animal refuse. But it was now once again being said that one should have only starch or sugar foods at one meal, fat at another, and so on—a wholly irrational idea. He had no doubt that there would soon be a chivalrous war upon vitamins.

Professor Mottram told his audience how to distinguish a fad from a fashion. A fashion became a fad when it needed emotion to defend it. Sometimes there was an unctuous rectitude about the faddist. He knew exactly what food it was within the last twenty-four hours that had disagreed with him, though Francis Bacon pointed out that it would take an enormous amount of experimentation before a particular mince-pie could be incriminated. The lecturer was sometimes called in to suggest an economic diet for a family, and when a wife greeted one of his suggestions with the remark that her husband would not eat that, he knew perfectly well that she would not eat it either! Professor Mottram himself let emotion creep in when he went on to denounce the brown bread fanatics, the anti-starch, anti-sugar, and

anti-acid fanatics, the anti-meat fanatics, the anti-purine-bodies fanatics, the intestinal toxæmia fanatics, the roughage fanatics, the slimming craze, and the so-called nature cure. The only food fad he did not denounce was the fad of having no food fads at all.

PRESENT-DAY NEEDS

The great need of to-day was more mass research into the problems of diet. Boys entering a well-known public school, for instance, compared with boys entering elementary schools, were from 1½ to 2 inches taller and from 7 to 11 pounds heavier, and it was suspected that the difference was largely due to food. The difficulties in research were the cost, and also the fact that man, with his complex psychology, was the worst research animal in the world, his psychological reactions towards food being almost as strong and disturbing as towards sex. Auto-suggestion explained the vogue of many patent medicines and patent foods. Most of the symptoms which arose from stasis of the colon were psychological and not chemical at all. Anything that removed that stasis gave a sense of well-being, and the individual, feeling better, went on taking the patent food or patent medicine until a vicious circle was created. Commercial firms had scientific men in their employment who seized on the latest discoveries in dietetics and exploited them. He spoke of the enormous amount of advertisement space occupied by patent foods in all classes of periodicals.

The British Medical Association, which had done a useful service with regard to secret remedies, might do yet more with regard to patent foods. One food which was brought to him by a nurse for investigation was advised for babies from birth, but as far as could be analysed it consisted almost entirely of starch and cane sugar, and if any baby thrived on that food it did so on the milk with which the food had to be made up. There ought to be analysis of all patent foods, and an insistence on an accurate description of them in advertisements.

Another need was for trained dietitians in every hospital of reasonable size—so far there were only a paltry half-dozen of them—a good deal of whose work should lie in the out-patient department. They should also have the opportunity of instructing medical students in dietetics. Post-graduate courses in the subject were desirable, also a general elementary instruction of the public through the B.B.C., health visitors, sanitary inspectors, district nurses, and teachers. What was good enough for our grandparents to eat was not perhaps good enough for us, because in the meantime, though called by the same name, it had become something entirely different. University centres for the training of teachers in dietetics were desirable. The principles of dietetics, so far as that subject had become a science, were very simple: that a mixed diet was essential, which mixed diet must contain first of all dairy food—milk, butter, cheese, and eggs—secondly, market garden produce—salads, green vegetables—and, thirdly, food from the sea. There were no fads in diet, and only one fashion should be allowed, namely, to eat a mixed diet.

A hearty vote of thanks was accorded to Professor Mottram on the motion of Dr. W. ASTEN.

At the last general meeting of the International Association for the Prevention of Blindness and of the International Organization against Trachoma, held in Paris, with Professor de Lapersonne in the chair, reports on various aspects of the trachoma problem were presented, and these have now been issued in pamphlet form (Imprimerie Alençonnaise, Rue des Marcheries, Alençon). The principal contribution is a survey by Mr. A. F. MacCallan, F.R.C.S., of trachoma in the British Colonial Empire, its relation to blindness, work of relief, and preventive action. The address given by Professor Emil de Grosz of Budapest on that occasion is published as a separate leaflet by the Royal Hungarian Press. On behalf of the American Ophthalmological Society and other parties the Downer medal was presented to Professor de Lapersonne for his outstanding work in ophthalmology and the prevention of blindness.

MR. HOLMES AND DR. WATSON

MR. HOLMES AND DR. WATSON

[THE BRITISH
MEDICAL JOURNAL]

[1886-1934]

When Arthur Conan Doyle was a medical student at Edinburgh in the late 'seventies he came under the influence of Joseph Bell, surgeon to the Royal Infirmary, whose gift of quick perception and rapid reasoning from small observations he turned to good account later. In 1886, when practising obscurely at Southsea, Conan Doyle hit on the idea of an amateur detective who should apply the methods of Joseph Bell to the unravelling of mysteries, with a sort of medical Boswell as foil and showman. Thus arose Mr. Sherlock Holmes, Dr. Watson, and *A Study in Scarlet*. Conan Doyle then came to London in the hope of making a name in ophthalmology, but no patients knocked at the door of the house in Montagu Street, Portman Square, and he filled his time by writing further adventures of Sherlock Holmes for the *Strand Magazine*. Now, forty-eight years after his creation, and four years after the death of his creator, Sherlock Holmes, with the lovable but absurd Watson, has passed into the realm of historical figures; in the minds of millions of people they are far more real than many of their living acquaintances. "His methods, his life, the documents in which his career is related, his friend and biographer, Dr. Watson, have all been investigated and made the topic of mock-scientific hypotheses." The game still goes on, and we are privileged to publish below a report of the inaugural meeting of the Sherlock Holmes Society. Appropriately enough, in view of all the circumstances—Joseph Bell and Conan Doyle were medical graduates of Edinburgh, John H. Watson had been a house-surgeon at Bart's, and met Sherlock Holmes there—the company included two members of the medical profession. We are glad to recall, too, that Dr. Watson was a regular reader of the *British Medical Journal*.

THE SHERLOCK HOLMES SOCIETY

The first dinner of the Society was held on the evening of Derby Day, Wednesday, June 6th, 1934, at Canuto's Restaurant in Baker Street. The following members were present: Dr. H. R. L. Sheppard, C.H. (in the chair), Mr. Ivor Back, F.R.C.S., Mr. E. M. Behrens, Mr. H. W. Bell, Mr. Anthony Berkeley, Miss Winifred Blazey, Mr. Denis Browne, F.R.C.S., Mr. C. M. Givens, Mr. R. I. Gunn, Mr. Gerald Hopkins, Miss Lanthé Jerrold, Mr. Gerald Kelly, R.A., Miss Gladys Mitchell, Mr. F. V. Morley, Mr. Stanley Morrison, Mr. E. R. Punshon, Mr. S. C. Roberts, Miss Dorothy Sayers, Miss Helen Simpson, Mr. Dominick Spring-Rice, Captain A. E. W. Thomas, D.S.O., M.C., Mr. Richard Heron Ward, Mr. K. Hobson, and Mr. A. G. Macdonell (hon. secretary). A genial note of welcome was struck by placing in front of each member a copy of Mr. Roberts's masterly study of Dr. Watson.

Two members arrived, it is understood, in a hansom cab, and two at least drank Beane because it was Dr. Watson's choice on a notable occasion. At the close of dinner a happy inspiration of Mr. Kelly's led to the appearance of a dish with a large metal cover, the removal of which by the Chairman, temporarily inveigled into the role of "Tadpole" Phelps, disclosed a facsimile of the Naval Treaty. This was followed by the presentation to the Chairman of copper beech leaves and orange pips by Miss Simpson and of an ear-flapped travelling cap by Mr. Spring-Rice. These unexpected and ingenious touches of local colour put the company in the best of humour, and served as an admirable introduction to the business of the evening.

The proceedings were opened by Mr. MACDONELL, who won unanimous approval for his proposal that the Society should elect Dr. Sheppard its President in recognition of his services in forcibly resuscitating Sherlock Holmes. (Later in the evening the President described the exact nature of the pressure which he and two friends applied to Sir A. Conan Doyle for this purpose during an I Zingari tour.) Mr. Macdonell then referred to various messages of greeting which he had received from, among others, Mr. Vincent Starrett and Mr. Desmond MacCarthy, and read extracts from a letter written by Mr.

T. S. Blakeney from a town in Southern India, which must, as several members eagerly exclaimed, have been Pondicherry.

Mr. Ivor Back was then asked to speak on Dr. Watson's medical qualifications, and responded by reading a letter which he had recently received from him. It appears that the doctor is now eighty-two years of age, but still has a few patients, one of whom, suffering from the loss of a big toe, he proposed to send to Mr. Back for examination. Advancing years, however, have shaken Dr. Watson's confidence in his professional powers, and he frankly admitted to his correspondent that he felt that he was now an even greater danger to the public than when he recommended strychnine in large doses as a sedative.

Mr. MORLEY then rose to read a cryptic telegram of greeting to the Society from the Gasogene of the Baker Street Irregulars. He explained that the latter are a body of enthusiasts established in New York, and that the Gasogene is their chief officer, the other two being the Tautalus and the Com-missionaire. The Society's interest in its American counterpart was increased by the extracts which Mr. Morley read from the Irregulars' highly original constitution, while his eloquent plea for a memorial plaque in Baker Street, or, if this should re-kindle the fires of controversy, in Montagu Street, obviously appealed strongly to his fellow members' sense of fitness.

A reference by Mr. Morley to the unsolved problem of how two, or possibly three, Moriarty brothers each came to bear the name of James gave Mr. GERALD KELLY his cue for a brilliant diatribe on the subject of Moriarty's Greuze. He challenged Holmes's argument that the acquisition of a picture by this artist presupposed an income far in excess of a professional stipend: the Vernet blood in his veins may well have caused Holmes to set a misplaced value on Greuze's work. Alternatively, why should not "La Jeune Fille à l'Agneau" have been a liability inherited by Moriarty from his father, whose unimaginative choice of names for his sons revealed him as a man of indifferent taste? Or again, might not Holmes himself have planted the work on his arch-enemy with the deliberate aim of undermining his moral?

Mr. ROBERTS and Mr. SPRING-RICE continued the discussion, the latter drawing attention to the curious incident of the train which left Winchester and arrived at Victoria after the race for the Wessex Cup. Mr. BELL propounded an ingenious theory that, notwithstanding Holmes's descent from country squires, his familiarity with London dated from early days; the evidence being that the thoroughfare which he identified as Robert Street in 1886 had for a number of years previously been renamed Robsart Street.

Miss SAYERS then proceeded to improve on Mr. Morley's proposal by asking why, if mere creatures of the imagination, like Peter Pan, are to be commemorated with statues, this honour should be withheld from national figures such as Sherlock Holmes and Dr. Watson. Nay more, let members consider the claims of Mrs. Hudson, that paragon of land-ladies, whom Baker Street Irregulars could not dismay, nor thoughts of vanished tidiness betray. Does not she, nor Happy Warrior of below-stairs, whom every kitchen-maid should wish to be, deserve a statue if anyone does?

So far Miss Sayers was on safe ground, but her next excursion landed her in a heated controversy. An incautious reference to Cambridge as Holmes's university brought Mr. MACDONELL to his feet with the indignant rejoinder that anyone who meant to study the exact sciences must have chosen Edinburgh. Miss Sayers replied with spirit, citing chapter and verse in support of her view, but Mr. Macdonell remained unconvinced. Meanwhile the champions of Oxford discreetly bowed their heads before the storm.

Discussion of two questions of future policy concluded this first and highly successful meeting of the Society. One was concerned with its form of government, and on this point Mr. Macdonell advocated an autocratic Soviet, of preferably one person, to deal with such questions as the number and election of members, and disarmed criticism by proposing himself as the Soviet. That this proposal was entirely to the taste of his fellow members was evident from the way in which they endorsed Mr. Back's thanks to the Secretary for his previous labours on their behalf.

The remaining question was that of future meetings of the Society. It was agreed that not more than two dinners should be held each year, and that the choice of Derby Night for one of them could not be improved upon. Mr. Back's plea for the anniversaries of Holmes's and Watson's birthdays would have gained more support but for the total lack of evidence as to when these anniversaries fall. Ultimately it was decided that the second dinner should be held in November. This, it was generally conceded, would give the Society the best chance of meeting in a thick yellow fog, or, failing that, in a high autumnal wind.

R. I. G.

Scotland

Central Midwives Board

The examinations of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, have just concluded, with the following results:

Out of 164 candidates who appeared for the examination, 140 passed. Of the successful candidates twenty-seven were trained at the Royal Maternity Hospital, Edinburgh; fourteen at the Elsie Inglis Memorial Hospital, Edinburgh; thirty-five at the Royal Maternity Hospital, Glasgow; nine at Stobhill General Hospital; two at the Eastern District Hospital; four at the Western District Hospital; nine at the Govan Maternity Hospital; eleven at Bellshill Maternity Hospital; two at Motherwell Maternity Hospital; two at Barshaw Maternity Hospital, Paisley; nine at the Maternity Hospital, Aberdeen; nine at the maternity department, Royal Infirmary, Dundee; five at the maternity department, Royal Infirmary, Perth; and the remainder at various recognized institutions.

Environment as a Cause of Mental Deficiency

The annual report of Dr. W. D. Chambers, physician-superintendent of James Murray's Royal Asylum, Perth, shows that on April 1st, 1933, there were 180 patients on the register, and that during the year 107 patients were admitted, of whom seventy-six were voluntary. The number of discharges included seventy-two patients recovered or relieved, nine unimproved, and eighteen deaths, leaving 188 patients on the register at the end of the year. The number treated during the year was 287. The report states that in recent years too many loose but dogmatic assertions have been made concerning the spread of mental deficiency and the decline in the mental and physical health of the population. There is still a widely held conviction that mental disorders are mainly due to faulty heredity to the exclusion of other causes, but as time goes on there is less and less excuse for hasty and ill-founded conclusions. Although there have been observations on the occurrence of mental disorder or defect in succeeding generations of certain families, little attention has been given to the number, quality, social value, and ability to survive among the healthy members of those families. The report of the Mental Deficiency Commission in 1929 recorded an incidence of mental defect in England and Wales of 8 per 1,000, but the Commission was unable to obtain evidence that the number of defectives was any greater than in previous generations. The Departmental Committee on Sterilization in 1934 found no evidence that mental deficiency was increasing at any notable rate. The difficulty in determining the cause of defect in any given case is to assess the comparative value of inheritance and of environment. Environment is apt to be regarded in too narrow and restricted a sense. Children brought up in circumstances of poverty, hardship, and inefficiency might with a perfect genetic inheritance grow up to be burdens on the community. On the other hand, persons from an obviously bad and weak stock might have an easy passage through life, escaping severe mental and physical strain. The effects of environment are usually given due weight in the case of psychotic breakdown in adult life, but their equal importance in cases of mental defect appearing in early years is only now becoming realized. At least one-quarter of all cases of mental defect are wholly environmental. Definite knowledge concerning the inheritance of mental disability is at the present time scanty, and could not possibly justify interference in any general way in social, political, or racial problems. Those

who urgently demand sterilization on a large scale must themselves be suspected of pretentious or even sadistic tendencies. Referring to the necessity for early treatment of mental illness, the report states that patients who suffer a mental breakdown will probably respond to immediate treatment by complete recovery, and in any case the proportion that can be restored to moderate health by investigation and treatment at an early stage is highly satisfactory. The case most likely to be neglected is that of the patient suffering from depression, who is apt to be allowed to drift until prospects of good recovery are greatly impaired. Such patients show little disorder of conduct, and the reserve associated with their condition is apt to conceal the severe disorder that is frequently present.

Ireland

Milk Bill (Irish Free State)

The text of the Milk Bill, already read a first time in the Dáil, has been published. The Bill is entitled "an Act to make further and better provision in relation to the production and sale of milk with a view to improving the standards of purity and wholesomeness thereof." Part III, Section 23, provides that this part of the Act applies to (a) each of the following diseases—namely, tuberculosis, typhoid fever, paratyphoid fever, diphtheria, membranous croup, scarlatina; and (b) every other disease which may from time to time be declared by an Order for the time being in force made under this section to be a disease to which Part III of the Act applies. The Minister may also from time to time, by Order made under this section, declare any disease (being a disease which in the opinion of the Minister is likely to be caused by any infected or contaminated milk) to be a disease to which Part III of the Act applies. Section 24 (1) is concerned with the stoppage of supplies of milk likely to cause disease, and provides that if the medical officer of a sanitary district has reason to suspect that any disease to which this part of this Act applies is caused, or likely to be caused, by the consumption of any milk which is being exposed or kept for sale within such sanitary district, he shall ascertain the location of the dairy in which the animal or animals from which such milk was obtained is or are kept, and thereupon the following provisions shall have effect: (a) if such dairy is within such sanitary district he shall examine the dairy, and, if he thinks fit, any person engaged in the service thereof, or who may be resident in any premises where any person employed in such dairy may reside, and shall if necessary require the veterinary inspector to accompany him and to examine the animals therein; and (b) if such dairy is situate in another sanitary district, he shall forthwith serve by post on the medical officer of such other sanitary district a notice of the facts of the case and the location of such dairy. Thereupon, the medical officer of such other sanitary district shall do the following things: (1) (i) He shall examine the dairy, and, if he thinks fit, any person engaged in the service thereof, or resident in the dairy, or who may be resident in any premises where any person employed in such dairy may reside, and shall, if necessary, require the veterinary inspector to accompany him and to examine the animals therein; and (ii) he shall report to the sanitary authority whose medical officer he is and to the medical officer by whom such notice was served, the result of such examination and any action taken by him under the next following subsection. 2. If the medical officer of a sanitary district, who has in pursuance of the immediately

preceding subsection examined a dairy, is satisfied as the result of such examination that any disease to which this part of the Act applies is caused or is likely to be caused by the consumption of milk supplied from such dairy, he may make an Order (in this section referred to as a Prohibition Order) prohibiting the dairyman, either absolutely or unless such conditions as such medical officer may think fit to insert in such Order are complied with, from selling any milk from such dairy or from any particular animal or animals therein so long as such Order is in force. In boroughs and county health areas where there are no whole-time medical officers of health, provision is made for the discharge of their duties by dispensary doctors in their capacity of medical officers of health in their districts. Section 28 provides for the prohibition of the sale of milk from cows suffering from the following diseases: tuberculosis of the udder, any tuberculous condition of the uterus, any form of tuberculosis in which tubercle bacilli are excreted, any septic condition of the uterus, acute mastitis, chronic mastitis, actinomycosis of the udder, retained placenta, and every suppurative disease of the udder, and every other disease which may from time to time be declared by an Order for the time being in force made under this section to be a disease to which this part of this Act applies. The Minister may from time to time by Order made under this section (a) declare any disease affecting cows to be a disease to which this part of this Act applies, (b) revoke any Order previously made by him under this section. Section 30 makes provision for the appointment of bacteriological examiners, but does not

Tuberculosis in Belfast

In his report as Chief Tuberculosis Officer of the county borough of Belfast for 1933, Dr. Andrew Trimble shows that there has been a reduction of more than 59 per cent. in the death rate in the last fifteen years. He believes that the course of the disease is becoming more chronic and its type more fibrotic, which may explain the lengthening period now observed between the beginning of the disease and death. Whereas in 1915, 150 women were found suffering from pulmonary tuberculosis in proportion to 100 men, the figure in 1933 had fallen to 103. In 1915 there were 144 female deaths for every 100 male deaths; in 1933 the female figure had fallen to 92. Dr. Trimble suggests that Ireland is passing through a phase of relative sex incidence like that observed in England thirty years ago, and that Ireland will also pass through the same cycle in respect of the death rate later on. Of the 1,164 new patients examined in 1933 no fewer than 410 (35.6 per cent.) had had a definite opportunity of infection through contact with tuberculous patients. In the remainder also there was a strong likelihood of similar though unrecognized contact with sources of infection. Dr. Trimble insists that improvement of the living conditions of the people, especially in regard to the isolation and nursing of a tuberculous patient, is one of the most important factors in the tuberculosis campaign. He believes that the offensive habit of spitting in the streets and public conveyances is on the increase, and pleads for more general action against it. He has found the sedimentation test and blood cell assessment of great help in prognosis and the guidance of treatment. An interesting follow-up has been begun of patients whose sputum contains albumin or albumose without tubercle bacilli. There is great need of increased institutional accommodation for tuberculous patients. Patients have overflowed from the municipal sanatorium into Belfast Infirmary, but still the waiting list grows steadily. It is hoped that expansion of the Graymount Hospital for Tuberculous Children will be well under way before the

end of the current year. The scheme will provide accommodation for about 100 more children immediately, and for about 150 ultimately, suffering from the non-pulmonary (including the hilar) forms of tuberculosis. In over 80 per cent. of the children discharged last year the disease had been cured without any resulting physical abnormality. The Graymount Open-air School, working under very restricted and make-shift conditions, is proving nevertheless exceedingly valuable in the prevention of tuberculosis among child contacts. An appeal is made for a new school with modern equipment, and it is urged that many weakly children would benefit greatly by being taught at open-air schools, where the midday rest and proper food might ensure their growing up to be sturdy and healthy adults. Commenting on late notification of tuberculosis, Dr. Trimble incriminates mainly the delay before the patient will apply for medical advice. In this way this disease presents problems in prevention and cure unknown in almost any other realm of medicine. The demand for Grade A (T.T.) milk is steadily increasing in Belfast.

Poor Law Medical Officers

A comprehensive agenda was considered at a recent meeting of the Poor Law Medical Committee, appointed by the Irish Medical Committee to make a report to the General Council of Medical Associations. Dr. P. O'Dowd, T.D., was in the chair, and Dr. T. P. McDonnell, Athlone, was appointed secretary. Dr. T. F. Armstrong of Ferns, Wexford, and Dr. D. F. McCarthy also attended; Dr. A. D. Courtney and Dr. Raverty, Bray, sent apologies for absence. Dr. Falvey, Dublin, who was unable to be present, submitted a number of important questions for consideration by the committee. Among the many matters considered were: the panel system in Great Britain and Northern Ireland, a short history of the statutes in relation thereto, and the efforts made with regard to the establishment of medical benefits in the Irish Free State; conditions of medical education, methods of appointments, service, remuneration, promotion, sworn inquiries, and pension rights in the Irish Free State, Great Britain, and Northern Ireland; unemployment in the medical profession was also discussed, and in connexion therewith the appointment of a representative deputation to wait on the Free State medical licensing bodies in regard to the curtailment of the number of doctors becoming qualified. The secretary was requested to invite the co-operation of a number of medical colleagues who in the past had given valuable services, especially to the Poor Law medical services. The committee decided to request the General Council of Medical Associations to appoint a finance committee to draw up a scale of fees which would be fair remuneration for the duties performed by the Irish Poor Law medical officers. The committee, however, expressed the opinion that any scale less than £350 to £450 would be inadequate for the work which is now being done by dispensary doctors. Owing to the increased work of dispensary doctors, medical officers of health of their districts the committee considered a minimal salary of £40 per annum should be paid for the discharge of the duties of such officers.

Salary of R.M.S. of Armagh Mental Hospital

The Armagh Mental Hospital considered the request from the resident medical superintendent, Dr. Doris Allman, for an increase in salary. In a letter to the board she said she had occupied the position for three years, and had done her utmost for the benefit of the institution. Her duties and responsibilities were greater than those of her predecessor and her salary less. The committee had now Castledillon in addition to the main hospital, where fifty-two patients were housed, thus re-

lieving overcrowding. Many other improvements had been made, and a poultry farm was also in existence. Dr. Allman's salary at the time of her application for an increase was £600 with £150 allowances per annum. Her predecessor's salary was £700 with £200 allowances per annum. The committee granted Dr. Allman an increase of £100 per annum.

England and Wales

Bournemouth Health Services

A circular tour on July 27th, arranged by the Bournemouth Corporation, enabled a party of those attending the Annual Meeting of the B.M.A. to obtain an inside view of some of the health services and new housing schemes, being conveyed from point to point by a Corporation omnibus. Two clinics were visited. The first, in Madeira Road, was a house in grounds bought about three years ago for £4,000, and adapted for the purposes of ante-natal, dental, and ophthalmological work. The dental department, which contains an x-ray apparatus, is conducted by a part-time dentist, any necessary anaesthetics being given by an assistant medical officer of health. The arrangement of the rooms is such that as many as thirty cases can be dealt with in two hours, the in-coming patients not meeting those who have just been treated—a very important matter in the case of children. Ante-natal cases requiring dental work are also treated here. The ophthalmological department includes a large room, which is also utilized for lectures to midwives and others. In addition to the ante-natal work, which is on the usual lines, it is proposed in September to begin maternity welfare activities on more comprehensive lines. The site has been well chosen in view of the increase in the working-class population. A contrast was afforded later in the tour by a visit to the Moordown Infant Welfare Centre, the work of which is carried on in a building hired for each weekly occasion from the local Congregational Church authorities. The schoolroom here is of adequate size for use as a waiting room and for the distribution of such accessories as infant foods and clothing, while there is also a good weighing room, a room for the medical officer, and sufficient accommodation for perambulators. There are nine infant welfare centres in Bournemouth. The itinerary included the Overcliff Drive, with its evidence of continued expansion of residential sites and good-class houses. Many of the tourists were particularly interested in the two types of sewage disposal illustrated, the first to be visited being the historical Hord Lane Disintegrator Station. With a view to the elimination of any possibility of foreshore fouling careful experiments were conducted by Bournemouth sanitary engineers some time ago, as the result of which it was found that special methods of preparation would undoubtedly be required before the effluent was discharged in the neighbourhood of Hengistbury Head. In the town there are now five groups of disintegrator outfalls, of which the Hord Lane one was typical. Here was demonstrated the way in which the sewage was minced by a cutting blade and revolving propellers, discharged in forty feet of water, and dispersed ultimately in cone form when rising to the surface, in order to be more available for destruction by marine organisms. These centrifugal propellers are set to 1 1,000 inch. The effluent is discharged at all states of the tide, which in this locality is double in the twenty-four hours, and has an average rise and fall of only six feet. It was pointed out that Bournemouth had been the pioneer in this method of sewage distribution. The other sewage disposal works

visited was at Kinson, situated in part of the area taken over three years ago when the scheme was in process of construction, and so had to be completed. Here in operation was seen the most recent activated sludge method. The sewage comes first to detritus tanks, where such large components as rags are arrested by screens. The clear fluid goes to filters before being passed into the River Stour. The sediment is collected and pumped up into digestion tanks of the aerobic kind, no forced ventilation being employed. It is then subsequently pumped out on to drying fields of clinker beds. The recently established Hord housing estate was the first to be visited. Here there are 166 houses of the non-parlour type, erected at a cost of £470 each and let at a weekly rental of 10s. 5d. Difficulties encountered here were the cost of the land and the prevalence of a high water rate, Bournemouth having no municipal supply, but depending on two companies, of which the one in this case charges a relatively high figure. Each house has one living room, three bedrooms, a bath room, and a kitchen. The other municipal housing estate visited was at Kinson, where there are 102 houses erected at an all-in total cost of £360. There are two slightly different forms of non-parlour house, let at 9s. 5d. weekly. In one form the living room extends through the length of the house, having a good window at each end. Each kitchen has a gas copper, and it was stated that practically no inconvenience resulted from the steam. The party proceeded to the Bournemouth Gas and Water Company's waterworks at Alderney, where tea was provided by the directors in a marquee near a filter bed. An excellent description was given of the work of pumping, filtration by sand, purification by waterweeds and algae, and subsequently by chloramine, and distribution to the town. The exceptionally well planned programme of the afternoon's tour elicited many expressions of gratitude from the party. The wise and progressive outlook of the municipality was whole-heartedly commended.

Water Supplies and the Drought

At a meeting of the Water Supplies Emergency Conference, held at the Ministry of Health on July 31st to consider the general situation resulting from the drought, it was stated that supplies are well maintained despite the scarcity of rain. Information has been obtained from 221 of the larger water undertakings, of which 190 report no serious shortage (present or prospective); twenty-seven report present shortage, but have measures in hand for dealing with it; and four, though not at present suffering from shortage, report that, though the position may worsen later, measures have been prepared for coping with it. Of 721 urban authorities (population less than 20,000) from which replies have been received 677 report no serious shortage; thirty-four report shortage, of which twenty-nine have schemes for new supplies, and others are relying on economies in consumption; ten more have sources available if needed, or are seeking new supplies. Of 510 rural district councils interrogated 260 report no serious shortage; 178 report serious partial shortage; and special action taken in 144 areas. In seventy-one others, where shortage is anticipated, supplies are available in twenty, and in fifty-one special action will be taken. Engineering inspectors of the Ministry continue to visit districts where the position appears to call for investigation. Twenty-eight applications have been received under the Water Shortage Act for special emergency powers, about half of which are for new sources of supply, and new powers have already been given in seventeen cases. Applications for grant under the Rural Water Supplies Act have been received from 154 rural districts, mainly for schemes of permanent improvement at an estimated cost of £2,299,000. Grant has

already been promised to sixty-eight councils for schemes costing £1,249,000. As regards the Metropolitan Water Board, recent rainstorms have helped matters, and, although the effect is only temporary, there is stated to be no need for alarm. Economy of consumption is, however, still required.

Leicester Royal Infirmary

Good progress was made last year with the work of extending and bringing up to date the accommodation generally at Leicester Royal Infirmary. One wing of the new Nurses' Home was completed and occupied, and there were many more applicants for training as nurses. Overstrand Hall, near Cromer, was subjected to extensive alterations, to serve as a convalescent home for female patients. A home for men in the grounds is projected, and thus the central convalescent home scheme of the Leicester and County Saturday Hospital Society is approaching completion. This seaside centre for convalescent treatment will free for the use of the Infirmary the Swithland Home for Men and Desford Hall House for Women. The acquisition of the first-named will place about fifty beds at the disposal of the Infirmary, and, if the convalescent home scheme for men develops, a further sixty beds will be available there. In this way the bed accommodation and services of the Infirmary will be substantially augmented. The financial outlook has brightened. Income exceeded expenditure for the third time in the last sixteen years, though by only a narrow margin. There were reductions in the amounts derived from annual subscriptions, donations, and the Hospital Sunday Fund, but the contributions from workpeople under the Hospital Saturday Fund exceeded those of 1932 by nearly £1,500, the total being £49,555. Legacies produced income double that of the preceding year. Increased income also accrued from hospital contributory associations, Road Traffic Act payments, and public authorities—on account of services rendered. There was a substantial addition to the number of endowed beds and cots. More radium was bought; the Royal Infirmary now possesses 497.7 mg. of radium element, and has been recognized by the National Radium Commission as an approved institution.

Salford Royal Hospital

In the annual report of the board of management of Salford Royal Hospital for the year ended December 31st, 1933, it is announced that the cost of treating patients for injuries resulting from traffic accidents increased over that in the previous years and reached a total of £1,087, towards which only £221 was recovered. Heavy pressure of work in all the departments indicated how urgent was the need for extension, but the financial position resulting from serious shortage of income in recent years made it impossible to proceed with the plan of enlargement which has been prepared. The out-patient department was built twenty-three years ago, and the work of the surgical and medical staffs is now being regrettably handicapped by lack of room. In 1920 fourteen beds were set aside for paying patients; during the year under review the number admitted was 135, as compared with 128 in the previous twelve months. The deficiency on the year's working was £2,825, even though there was a reduction of expenditure by over £3,000. It is regretted also that the central scheme of workpeople's contributions has not received the support it merits, and basis hoped that greater efforts will be made to encourage a more general adoption of weekly contributions throughout the district to the Hospital Fund. With a view to infirmity a closer relationship with this Fund, a joint is hoped of representatives of all the local hospitals and Tuberculosis is in process of formation. General adoption

of this scheme would, it is calculated, yield sufficient funds to obviate the necessity of special appeals being made from time to time to wipe off deficiencies of income. It is mentioned that no special appeal for financial support has been made during the last twenty years, and £60,000 is now urgently required to meet the bank overdraft and immediate necessities. An additional annual income of £5,000 is necessary to allow the present accommodation to be maintained. The number of patients admitted during 1933 to the wards was 4,031, as compared with 3,965 in 1932. The average cost of each in-patient was £8 1s. 3d. in 1933, a reduction of 14s. on the previous year.

Papworth Tuberculosis Settlement

Sir Pendrill Varrier-Jones, medical director of the Papworth Village Settlement, in his annual report states that 1933 witnessed greater activity than any previous year in the history of Papworth. Not only has the number of hospital beds increased, but advanced cases have been rehoused and observation wards provided for those who come for treatment and training: there are also private wards for paying patients. Thanks to the generosity of the Bernhard Baron Trustees a large new hospital has been erected for men, and also a well-equipped out-patient department for housing the various clinics, which include a new x-ray department. As a consequence of all these activities Papworth Hall has been reorganized and the administrative staff now have at last adequate accommodation for their work. This and the other reports on the year's work have been printed as an illustrative pamphlet by the Papworth Press, and were approved at the seventeenth annual general meeting, held in London on July 11th. Fifteen days later the Duke of Gloucester visited the Settlement, where he was met by the President (Sir Humphry Rolleston), by the Lord Lieutenant of Cambridgeshire (Mr. C. R. W. Adeane), Lady Linlithgow, and the Duchess of Northumberland. His Royal Highness then made a tour of the village and its workshops and inspected the new hospital, towards the building of which the trustees of the late Mr. Bernhard Baron have given £20,000. He then went to the site of the new surgical block and laid the foundation stone.

London Maternity Hospitals

Consideration of the annual reports for 1933 of various London maternity hospitals reveals an increasing tendency of expectant mothers to enter institutions for their confinements. In the General Lying-In Hospital, for example, whereas in 1932 there were 887 out-patients attended in their homes, only 776 were so treated in 1933, while the in-patient total rose in the two years from 1,040 to 1,065. Similarly at Queen Charlotte's Hospital the capacity of the institution to meet the demand for in-patient treatment has become inadequate. Beds are booked for a longer period ahead than hitherto, and there is no diminution in the number of emergency cases. The total number of in-patients was 2,771, contrasting with a decrease in the number of out-patients. It is pointed out that the Local Government Act of 1929 has resulted in the transfer to local authorities of largely increased accommodation for maternity services, both actual and potential, and the consequent loss of patients to training hospitals with districts is a serious matter. A similar fall in the number of out-patients is recorded by the City of London Maternity Hospital. At the General Lying-In Hospital, where 444 prospective mothers had to be refused admission owing to lack of accommodation, the possibility of providing beds for patients able to contribute towards the cost of treatment was considered during the year under review. Discussions have been held with the

Charity Commissioners, and a thorough investigation has been made of the possibilities, financial and otherwise, but the matter has had to be left in abeyance. The year was, however, marked by the completion of the extension scheme, launched in 1927, for the building of an up-to-date nurses' home and an out-patient department. The cost of erecting and equipping the new building has been met by the special extension fund, with the exception of the comparatively small sum of £350. In view of the discussion on the results of ante-natal care at the Annual Meeting of the British Medical Association this year at Bournemouth, and of earlier correspondence in these columns, special interest attaches to the references to this matter in the various reports. At Queen Charlotte's, for instance, the maternal mortality rate in booked cases delivered in the main hospital was 5.3 per 1,000. The rate for district out-patients was 2.1 per 1,000, giving a general rate for booked cases of 4.07 per 1,000, compared with 44.4 per 1,000 for emergency cases. Whereas the

booked cases attend the hospital ante-natal department, and have therefore been under the care of the hospital for some time before confinement, the emergency cases are sent in by medical practitioners at the last moment, and are generally in a critical condition. It is concluded, therefore, that the statistics reflect in no uncertain manner the vital importance both to mother and child of early and regular ante-natal care. At the City of London Maternity Hospital all booked patients have similar ante-natal supervision, while at the East End Maternity Hospital the homes of all patients booked for attendance in the district are visited; 445 special visits were paid in 1933 to patients suffering from ante-natal disorders. In the last-named institution there were no maternal deaths during the year; Caesarean section was only required in one instance, and in the single case of eclampsia which occurred the patient had had no albuminuria during pregnancy, nor was it present on admission. She had five fits, and made a good recovery.

CORRESPONDENCE

The G.P., the Schoolmaster, and the Specialist

SIR.—I should like, if I may, to air a small grievance which I think must be shared by many and which ventilation may perhaps amend.

The custom seems to be growing among head masters and mistresses and house masters of boarding schools of writing to parents at the end of term somewhat as follows: "We are sorry to find that your child's tonsils are in a very unhealthy state, and we trust that you will have them removed at the earliest possible moment." Or, "William's [or Julia's] health has not been at all satisfactory this term, and we hope you will take him [or her] to see a heart, lung, nerve, or gland specialist without delay." Whether or not the letter takes exactly this form, it is certain that something very like a command is issued for the child to be taken to see what is considered to be the suitable specialist or to have some specific operation. Rarely, if ever, is the parent advised to consult the family doctor.

Now it often happens that the family doctor, having known the child since infancy, is perfectly aware of the large tonsils, murmur, tachycardia, cough, fidgetiness, prominent thyroid, or what not, but has excellent reasons for thinking that neither specialized investigation nor active interference would be at all good for the child. In any case his opinion ought surely to be of value, and there can be no justification whatever for attempting to circumvent him. Often enough, of course, he is not circumvented at all, but only ruffled. At other times the parent takes the line of least resistance, considerable embarrassment is caused, and the child's health is not always improved. It is probably better not to quote specific instances, but the situations which arise are sometimes very curious and even entertaining.

Could not the medical officers attached to the schools, most of whom must themselves be also family doctors, impress on masters and mistresses the fact that the child probably has a doctor at home who ought to be consulted, and if there is really some condition requiring attention, would it not be far better that they themselves should write a note to the child's doctor? I cannot doubt that sometimes they do, but I cannot remember ever to have received such a letter, though I have had experience of the other procedure many times.—I am, etc.,

H. J. [?], Aug. 10.

LINDSEY W. BATTEN.

Occupational Therapy

SIR.—Dr. A. J. Brock (*Journal*, August 4th, p. 231) expresses surprise that I should have stated from the chair at the conference in London on occupational therapy that the movement was of recent development.

"Recent" is, of course, a relative term, but in my remarks I gave a short historical survey of occupational therapy, and showed that it was essentially a movement of the present century, although it had been utilized in at least two instances in the last century. I have no authoritative knowledge of the extent to which it is employed in mental hospitals, but it may be of interest to record that it has been an essential feature at the Lord Mayor Treloar Cripples' Hospital and College since the foundation of the institution in 1908. This work at Treloar Hospital aroused the interest of the Board of Education, and on the advice of Sir George Newman, Mr. Lloyd George, then Chancellor of the Exchequer, recognized hospital schools, which became eligible for both educational and medical grants in 1911.

Such movements are easier to initiate in public than in private institutions. In the latter no Government aid is forthcoming. I believe the Morland Clinics are unique as a private enterprise in combining education and occupation for every suitable case in the chronic diseases there treated. It is a source of real gratification to record that many boys and girls under treatment at Morland Hall have continued their education with little interruption while treatment was in progress, and in many cases have been successfully prepared for entrance examinations to the universities.

The importance of this, to the better-class boy and girl, is that education is not interfered with by the incidence of disease, which may require up to two or three years' recumbent treatment. The value of this combined treatment and education cannot be overestimated for that social class where education is essential to a successful career.—I am, etc.,

Alton, Aug. 6th.

HENRY GAUVAIN

Pellagra in England

SIR.—Ever since I heard Dr. Louis Sambon lecture on the above subject some fifteen years ago I have been interested, and have been on the look out for it among cases seen in private and at hospital. It has been shown that it was endemic in Scotland and England, apart from asylum cases. I shall not readily forget his answer to a doctor in Cumberland who, after reading a description by

Sambon of the disease, wrote to say he had such a case, but that the patient was dying. Sambon wrote to the doctor to say he was coming to see it. He received a telegram, "Patient dead," to which Sambon replied, "Coming all the quicker."

I have had the opportunity of seeing since that time two cases in females aged from 40 to 50, and one other in a young lad of 18 or so. It is impossible to diagnose such cases in the early stages—in this country at least. Probably the photodynamic factor helps in the earlier diagnosis of cases in Egypt and Eastern Europe by bringing into prominence the characteristic skin pigmentation. Gastro-intestinal symptoms which do not respond to any known therapy, medical or surgical, and are of considerable duration were the primary complaint in my cases. In my first female case I was led to try the effect of a Coffey's suspension for severe gastroparesis, but without result. The great depression, followed by the skin pigmentation which appeared not long afterwards, gave one the clue to the correct diagnosis. This patient was subsequently found with her head in a gas oven.

The other female case resembled a pernicious or aplastic anaemia—there was a prolonged history of relapsing gastro-intestinal attacks, with diarrhoea, tingling and numbness in the hands and feet, sore tongue, dysphagia, severe pains in the epigastrium, and acute "blood breaks" resulting in a reduction of the haemoglobin to 30 per cent. The anaemia was, however, of secondary type. Gastric analysis revealed an approximately normal HCl, but an x-ray of the alimentary tract showed marked hypertonicity. These attacks of epigastric pain were accompanied by the passage of urine containing excess of indican, urobilin, and urobilinogen, and were the prelude to profuse offensive diarrhoeas. Kaylene powder and pil. ferri redactum grains x a day were of use during these attacks, although injections of calcium sandoz 10 c.cm. and paroidin (P. D. and Co.) m v often acted magically in relieving the pains and diarrhoea. The exhibition of magnesium thiosulphate, as suggested by Sabry and with a view of combating an intestinal hepatic anaphylaxis, seemed to help. It was the exposure of this patient to the sun and fresh air which gradually led to the diagnosis. Her face and hands rapidly tanned, until the latter began to desquamate round the knuckles, large, thin, lifeless, crinkly scales making their appearance. The elbows also appeared dirty and scaly. Even so, one might have regarded the condition as just "erythema solare," as it rapidly responded to glyc. acid. carb. applications. A vaccine containing haemolytic streptococci and *B. coli* prepared from faeces seemed to help. As the patient became very depressed, and suffered from recurrence of the abdominal pain and diarrhoea, she was allowed home, where she seemed to improve rapidly, her hands becoming normal and her facial pigmentation diminishing, the pearly sclerotics standing out in marked contrast to the background of yellow skin. This patient had always been freckled.

The tanning from the sun was so rapid that the production of melanin led one's thoughts to tyrosine and tyrosinase. In an adjacent bed was a patient with symptoms of thyrotoxicosis (and with urinary findings similar to those recorded above) who had tanned almost as severely. Now tyrosine is related to thyroxine and melanin. In the course of my work I have come across "epidemics" of illness, frequently in springtime, which suggested the production in the intestine of some product like tyramine. This is produced by certain forms of *B. coli*, with the property of decarboxylation. A change in the pH of parts of the bowel compels these organisms, as a means of self-preservation, to change their mode of living. Tyrosine is therefore broken down in two ways: (a) by decarboxylation into tyramine, or (b) into phenol by deamination and oxidation. Tyramine is oxidized by tyrosinase.

Some such explanation would account for many of the clinical features of pellagra and do away with the need for an extraneous factor like maize, velvet beans, etc.

The successful treatment of such cases by vitamin B₂ (yeast and liver extract) supports McCarrison's findings on the necessity of this for a healthy intestinal tract. The nervous symptoms and mental deterioration are supported by the findings of Ewins and Laidlaw—namely, that of the putrefactive products of tryptophan indole ethylamine is probably the cause of dementia praecox.—I am, etc.,

Darlington, July 21st.

R. CHALMERS.

Haemorrhage from Peritonsillar Abscess

SIR,—In the *Journal* of April 28th (p. 755) Dr. T. G. Wilson related a case of haemorrhage following spontaneous evacuation of a peritonsillar abscess. This account reminded me of a similar case which was under my care some twelve years ago when I was in general practice in South Australia. The history of the case was almost identical with that recorded by Dr. Wilson.

The patient was a lusty plumber who had been the victim of recurrent attacks of tonsillar suppuration. On the occasion in question his peritonsillar abscess discharged spontaneously after an illness of four days. Within a few hours severe haemorrhage from the abscess cavity started, and persisted with short intermissions and, in spite of every effort to check it, for two days. By this time he was in a dangerous exsanguinated condition, and it was clear that unless the bleeding was permanently stopped he would die. The presence of a trickle of blood into the pharynx made the administration of a general anaesthetic a hazardous procedure, and therefore it was decided to operate under local anaesthesia. After a dose of morphine and hyoscine the neck was infiltrated with 1 per cent. novocain, and the external, not the common, carotid was tied. The operation was not easy, as the presence of associated adenitis of the carotid glands compelled the removal of several of these before proper exposure of the bifurcation of the common carotid could be achieved. A dread of the possible cerebral sequels of tying the common carotid made me, in my inexperience, decide to tie the external branch. The result was very satisfactory, the patient making a speedy and uninterrupted recovery after immediate cessation of the bleeding.

As the literature suggests that ligation of the common carotid is not without risk of unhappy sequels, it seems to me wiser to tie the external branch—an operation which is rather more difficult and takes more time, but which meets the condition without interfering with cerebral blood supply.—I am, etc.,

J. B. DAWSON,

Professor of Obstetrics and Gynaecology,
University of Otago.

Dunedin, New Zealand, June 20th.

Splenectomy for Menorrhagia in Purpura Haemorrhagica

SIR,—In your issue of July 7th (p. 8) an interesting case of purpura haemorrhagica with menorrhagia was described by Dr. Stanley Hartfall and Mr. Carlton Oldfield, in which they stated that the only symptom was recurrent menorrhagia causing severe anaemia, that there was no bleeding from any other source, no purpura or spontaneous bruising, but that the latent purpuric state was revealed by the capillary resistance test. The last point is very interesting to those of us who have felt for some time that the capillary resistance test was at the present time necessary in differentiating a case of essential purpura haemorrhagica from other kinds. I have recorded five cases of the essential type, and in each one the capillary resistance test was positive sooner or later.

In a case which I published in the *Proceedings of the Royal Society of Medicine* nine years ago, of a woman aged 28 who had suffered from essential thrombocytopenic purpura haemorrhagica with very severe menorrhagia on

and off for some years, the thrombocytic count went down to 40,000, and occasionally to zero, after severe haemorrhages; the bleeding time was fifteen minutes, and the capillary resistance test was markedly positive. During one severe bout the red cells went down to 2,000,000. Purpuric spots used to come out in crops on the skin, lips, and nose, and occasionally the latter oozed for days together. Splenectomy, performed nine years ago, has been followed by cessation of all purpuric symptoms, menstruation has become absolutely normal, and she has enjoyed, and still enjoys, perfect health. The spleen in her case was normal in size clinically and at operation.—I am, etc.,

BERNARD MYERS, M.D., F.R.C.P.

London, W.1, July 28th.

Tests of Renal Function

SIR,—Dr. Robert Platt, in his letter in the *Journal* of July 21st (p. 138), chiefly objects to the urea clearance test because of "its obvious pretence to a scientific accuracy which it does not possess, even in its modified form." His objection is apparently based on the fact that a case clinically diagnosed as chronic uraemia showed a urea clearance better than the average for a group of cases with renal disease, and, therefore, that the urea clearance did not bear a sufficiently close relation to the clinical condition of the patient. But the urea clearance test is simply a test of renal function, whereas the clinical condition of the patient depends not only on the nature and extent of the disease of the kidneys but also on the presence or absence of disease elsewhere. In the same letter Dr. Platt refers to cases of his own "which were without serious renal insufficiency until heart failure occurred and, by lowering the blood pressure, caused oliguria and consequent uraemia." He recognizes, therefore, that the determining factor in the onset of uraemia may be heart failure rather than renal insufficiency.

The patient referred to by Dr. Platt had dizziness, headache, vomiting, cardiac hypertrophy, some arteriosclerosis, raised blood pressure, and albuminuria. There was, however, by ordinary tests, no impaired excretion of urea—that is, the blood urea was not raised, and the urea concentration of the urine, following the usual dose of urea, reached a high level in the second hour—namely, 3.19 per cent. I think Dr. Platt will agree that some part, at any rate, of the clinical manifestations shown by this case was due to cardiovascular conditions, so that the failure of the urea clearance to correspond to the gravity of the case as suggested by the clinical diagnosis does not prove that the urea clearance is not a fair indication of the state of the patient's renal function. Dr. Platt also states that he does not find in practice that the urea clearance test is as helpful as a dilution and concentration test, and examination of the blood for non-protein nitrogen and indican. I should like to know if he is here referring to the urea clearance test in its modified form, and, if so, if he has already carried out systematic comparisons of the modified test, and the procedure he prefers.

With reference to the subject of albuminuria in chronic nephritis, to which he refers, and his statement that he regards the presence of albuminuria (more than a trace) as a fairly good rough indication of involvement of the kidney (nephrosclerosis) in essential hypertension, I would refer him to the statement of Peters and van Slyke (*Quantitative Clinical Chemistry: Interpretations*, p. 703) that "in the nephrosclerotic type of the disease the quantity of protein in the urine is usually small, sometimes almost undemonstrable."—I am, etc.,

Leeds, July 31st

F. S. FOWWEATHER.

Evipan Anaesthesia

SIR,—I have been greatly interested in the recent letters on the subject of sodium evipan anaesthesia, but have hesitated so far to join in, having very little, though excellent, experience with the drug. As, however, Dr. Kuhne (*Journal*, June 9th, p. 1029) was emboldened to describe his experience of only two cases, I venture to describe here a series of ten, which, occurring in the Tropics and under unfavourable conditions, may prove of interest. My cases were all aboriginal Indian tea estate coolies, except two—an Indian clerk and a Chinese mechanic.

The Chinese was my first case, requiring complete endotracheal. Anaesthesia was complete for twenty-two minutes, but consciousness was not recovered for four hours. No ill effects followed. Next in order two adults were circumcised, two minor amputations were done, two fractured limbs set, two large sebaceous cysts excised, and in the tenth case evipan was used as an introductory anaesthetic in an operation for localized peritonitis. The coolie cases all required more than 10 c.cm. sodium evipan solution to effect proper anaesthesia. The peritonitis case was an exception, only 5 c.cm. being necessary. The Indian clerk also required only 5 c.cm. for successful circumcision to be done. The patient on whom I operated for peritonitis was a coolie aged 20, in a toxic state and also suffering badly from anaemia due to hookworm. Evipan anaesthesia was complete in two minutes. This was followed by chloroform, the anaesthetic commonest in tea estate practice, and it was noticed that only a very little was used (less than 4 drachms), in spite of the hot weather and the time taken for operation—one hour. Curiously, consciousness was regained half an hour afterwards, as against an average of two and a half hours in other cases. The patient made an uninterrupted recovery.

Points of interest are: (1) in no case was premedication with other narcotics used; (2) in no case were any ill after-effects observed; (3) in no case was the jaw observed to drop, although anaesthesia was complete; (4) in eight out of the ten cases the patients had anaemia, with haemic murmurs in three instances. In view of this last point the probability of sodium evipan being a powerful respiratory or cardiac depressant hardly seems correct. I can surely not have been merely lucky with my series. I am glad to note Dr. Montague Solomon (*Journal*, June 30th, p. 1187), with his longer experience, agrees with my findings. Sodium evipan is a drug I shall always use with confidence.—I am, etc.,

Assam, July 26th.

EDMUND BURKE.

Non-specific Colitis

SIR,—As one having extensive personal experience of this condition (surely the best school of learning), I would remark that Dr. J. T. Shirlaw (August 4th, p. 231) is both right and wrong in his statements on the question of carbohydrates and colonic irrigation respectively in this form of ill-health. With regard to carbohydrates, personal experience and facts derived from the treatment of patients put me in entire agreement with the advisability, even necessity, of cutting down sugar and starch in this condition. There would appear to be a definite failure in the metabolism of carbohydrates in colitis cases.

Colonic irrigation is a two-edged tool, which fact should be remembered if it is to be used successfully in colitis. In the "constipation" type of colitis, where the colon can be so atonic as to assume enormous dimensions, irrigation, if done sufficiently slowly, can be of very great

Obituary

M. S. PEMBREY, F.R.S., M.D.

Late Professor of Physiology, University of London
Professor Marcus Pembrey, a short notice of whose death appeared in last week's *Journal*, might well be called a "general physiologist"—general in the sense that the whole of Nature was his textbook, the living world his laboratory. Throughout all his work is found the attempt to adapt its applications and to make them practicable for the benefit of living organisms. He loved the country-side, and founded many of his observations upon the events of farm life.

The son of an expert Oriental linguist associated with the Clarendon Press, he obtained a science exhibition at Christ Church, Oxford, and graduated in arts in 1889. He took the M.B., B.Ch. in 1892, and the M.D. three years later. During his tenure of the Radcliffe

Travelling Fellowship, which he secured in 1890, he did research work in Würzburg and Kiel, returning later to Oxford as demonstrator of physiology under Burdon-Sanderson.

From this time onwards he began to publish valuable work on physiology, sometimes in collaboration with Professor J. S. Haldane.

From Oxford Pembrey went as lecturer in physiology to Charing Cross Hospital, and afterwards succeeded the late Professor Starling in a corresponding post, later converted into a London University professorship, at Guy's Hospital. In 1922 he was elected a Fellow of the Royal Society in recognition of his experimental work. It was in 1894 that Pembrey became a member of the British Medical Association, and he received B.M.A. scientific grants in the years 1906 to 1914 inclusive.

He was secretary of the Section of Anatomy and Physiology at the Annual Meeting of 1899, and vice-president of the Section of Physiology in 1904.

His early work was devoted to questions of heat production and temperature regulation. These investigations were of a comparative nature, and covered a wide range of conditions and species. Included in the series was the question of hibernation, and for this he studied the marmot, an association for which he will be long remembered by his students and assistants. From the temperature changes of hibernation he passed to the associated metabolism, and his measurements of the respiratory quotients of the marmot are almost classical. Respiration now provided his main field, and he studied the respiratory exchanges in muscular exercise and diseased conditions, notably diabetes; "second wind" and "stitch" were two problems of constant interest to him. The homely couplet

"After dinner rest awhile,
After supper walk a mile,"

furnished him with the text for his final work upon the reactions of the alimentary tract to muscular exercise. His papers are to be found mainly in the *Journal of Physiology* and the *Guy's Hospital Reports*. From 1906 to 1909 Professor Pembrey served on the War Office Committee on the Physiological Effects of Food, Training, and Clothing on the Soldier. He took a very active part in the work, and one can imagine the enthusiasm with which he tramped along with the troops

value indeed. Where, however, the main symptom is irritative diarrhoea with constant spasmodic pain, irrigation is definitely inadvisable, and grave harm may ensue to the tender membrane and to the mind of the patient from the resulting pain. There is probably no other treatment which should so definitely be kept in the hands of trained practitioners, and yet (? because we are so apathetic) colonic irrigation can easily be obtained from unqualified people or used in the patient's own home.—I am, etc.,
Oldham, Aug. 4th.

MARY G. CARDWELL, M.D.

The Swab in Diphtheria Diagnosis

SIR,—Dr. E. James (*Journal*, August 4th, p. 230) has undoubtedly exposed the main fallacies of the diphtheria swab. As medical officer to the isolation hospital for this area I have had some seventy cases of diphtheria admitted in the last six months, quite a number of which, though absolutely definite clinically, returned a negative swab.

The swab in diphtheria must, I consider, be regarded in the same light as the examination of sputum in tuberculosis—that is, a negative swab is no contraindication of the presence of the disease, while a positive one confirms the presence of the micro-organisms. In any suspicious case serum should always be administered whether a swab is taken or not, and in no circumstances should this be delayed pending the result—particularly in districts where immediate bacteriological examination is not available.

As to dosage, I entirely agree with Dr. James that at least 20,000 units should be administered, and this point should be accentuated, as there is still present among the profession a fear of giving larger doses than 8,000 units. As to this, I have personally administered up to 150,000 units in doses of 40,000 units, with no more effect than an irritating serum rash, allayed by hypodermic injection of pituitrin and/or calamine lotion. I may add that I invariably use Parke, Davis and Co's serum.—I am, etc.,
Bridport, Aug. 4th.

JOHN C. T. SANCTUARY.

Radical Cure of Hernia

SIR,—The descriptions in textbooks of operative surgery of the radical cure of inguinal hernia usually omit one useful step in the operation. I refer to the introduction of the forefinger through the neck of the sac into the abdominal cavity for the purpose of exploring the internal inguinal ring of the opposite side. Three of my recent cases have illustrated the value of this simple procedure. In two cases of right inguinal hernia a patent process was in this way discovered on the left side, and a double radical cure effected. In neither of these cases was the left hernia diagnosed before operation, though in one case it was suspected. In the third case, at an operation performed elsewhere, the patient's left inguinal region had been explored for hernia and no sac had been found. Protracted suppuration had followed the operation, and six months later the patient came to me with a scrotal hernia on the right side with the request that I would perform a radical cure of the right side, and would explore his left side to find and cure the hernia, if any, on that side. At the operation on the right side it was possible to palpate the left inguinal region and to determine the absence of a sac on the left side, thus avoiding further operation on that side.—I am, etc.,
Lautoka, Fiji, June 3rd.

PHILIP HARPER.

Aug. 11, 1934]

OBITUARY

on their experimental marches. Pulse, temperature, and water loss were investigated under a variety of conditions, and a very full report embodied conclusions of an essentially practical nature. Pembrey had very decided opinions upon teaching. He favoured the method of Socratic discussion, and objected strongly to what he called "spoon-feeding." It is true that, in the heat of discussion, his classes often rather wandered from the work in hand, and his students may not have acquired a vast store of academic knowledge, but he made them think for themselves and so helped them to stand on their own feet. He instituted classes in clinical physiology so that the students might see the direct application to man of the principles he inculcated. In his official capacity he was indefatigable, and he never hesitated to express his opinion when necessary. Candid criticism and cheery optimism characterized all his actions, and his due allowance was made for his love of argument, his advice was always valuable. Among his many duties was that of treasurer to the Physiological Society, and his report in that capacity was always a feature of the annual meeting: he usually succeeded in enlivening the monotony of figures with some merry quip or polemic thrust.

No portrait of Professor Pembrey would be complete without reference to his passionate interest in the preservation of the race. The problems of reproduction, in all its aspects, always attracted him, and he contributed many papers on the physiology of the foetus and newly born. A strong supporter of the family, he constantly preached what he would call "the morality of Nature," and he viewed with horror any schemes of artificial selection. To him the struggle for existence was essentially beneficial; pain was not "a supreme evil"; self-determination was to be encouraged at all costs.

By his untimely death his colleagues and students have lost a very real friend—one who was ever willing to lend a sympathetic ear, one who would stretch out a helping hand to those who were ready to make an effort, one who did not allow personalities to take precedence over principles.

The photograph reproduced is by Elliott and Fry, Ltd.]

D. NAUNTON MORGAN, F.R.C.S.I.

Past-President, South Wales and Monmouthshire Branch
By the death of Dr. David Naunton Morgan of Gilfach Goch, Bridgend, the South Wales Branch of the British Medical Association has lost one of the oldest and most respected of its members.

Naunton Morgan was born in Ystrad-Rhondda in 1862, and belonged to a well-known Glamorganshire medical family, members of which have practised medicine in the county for five or six generations. He studied medicine in the London Hospital, and took the qualifications M.R.C.S., L.R.C.P. in 1890. He then started practice at Gilfach Goch in conjunction with his uncle, the late Dr. H. Naunton Davies of Porth, who was the first Gold Medallist of the British Medical Association. Naunton Morgan soon established himself as an able and very reliable practitioner, and won the confidence of the whole community, retaining it until his death. His leaning was towards surgery, and in 1906 he took the Fellowship of the Royal College of Surgeons of Ireland. He was one of the senior surgeons of the Porth Cottage Hospital. From the time he qualified he took an active part in the work of the B.M.A., was an ex-chairman of his Division, an ex-president of the South Wales and Monmouthshire Branch, was the first president of the Rhondda Medical Society, and a member of the Glamorgan Panel Committee from its inception. He also represented Wales on the Central Medical War Committee during the war. Naunton Morgan found time to take part in the local affairs of the district, and was at one time chairman of the

then school board. He was placed on the Commission of the Peace for Glamorgan more than twenty years ago. He had the characteristics of many of his race. He was fiery and impulsive, but kind-hearted, good-natured, and generous to a fault—qualities which made him a very popular figure among all who knew him, and he was always looked upon as "one of the best." The immense concourse of people which attended his funeral at the Tonyrefail Cemetery, where he was laid to rest, was an eloquent tribute to his popularity and an expressive appreciation of his worth and work. He leaves a widow, four daughters, and three sons, two of whom are medical students. Two sons and one daughter predeceased him. One of the sons was a member of the profession, and was about to join his father in practice when he died.

THE LATE DR. JAMES W. STEEL

Mr. JOHN PATRICK, Glasgow, writes:
Everyone who knew the late Dr. James W. Steel, especially in Salonika in the days of the war, will appreciate the excellent notice which appeared in the *British Medical Journal* of July 28th, contributed by Mr. Saunders Melville. I would like to amplify the remarks made in regard to Jimmie Steel's musical gifts. To those of us who love music, but who are not possessed of the gift of a good "ear," the ability shown by Steel almost approached the wonderful. He could not read the simplest piece of music, and learning music from a score was to him a laborious business, and seldom attempted. Yet he could sit at the piano at a cinema exhibition and play straight on for two hours, varying his music with the character of the picture. I recall a summer afternoon in the anteroom of the officers' mess of the 28th General Hospital, when Steel played the piano to me as his only auditor. Amongst other pieces which he played was that exquisite Prelude of Chopin, known, I think, to musicians as "The Rain Drop." After he had finished I told him that it was very beautiful, but not quite as Chopin wrote it, and his reply was, "Yes, I know, but I have only heard it played twice, and I have never seen the score." This peculiar gift possessed by Steel is one of great rarity. Throughout his war service he was most unsparing and ungrudging in his use of it, and his playing was in constant demand in many units.

Dr. EBENEZER WILLIAM DIVER, who died on July 15th, had interested himself particularly in the prevention and treatment of tuberculosis. Born in 1865, he received his medical education at University College, London, and at Newcastle-on-Tyne. He graduated M.B. Durham in 1889, and the next year obtained the diplomas M.R.C.S., L.R.C.P. In 1896 he proceeded M.D., and in 1913 received the diploma L.C.P.S. of Alberta, Canada. One of the earlier promoters of sanatorium treatment, he was for some time medical officer and proprietor of the Belle Vue Private Sanatorium, Shotley Bridge. From 1902 onwards he published articles and pamphlets on the treatment of tuberculosis, with special reference to its clinical manifestations and the steps to be taken in eradicating it from the community. He later practised in Eltham Park. He was elected a member of the British Medical Association in 1893 and was chairman of the Woolwich Division in 1926-7.

We regret to announce the sudden death, on July 26th, at the age of 60 years, of Dr. JAMES ROSS of Liverpool, one of the best-known practitioners in Walton. He was born in Ballymena, County Antrim, and was educated at Queen's College, Belfast, and the Edinburgh College. He qualified at Edinburgh in 1899, and in 1925 took the degree of M.D. of Durham University. Dr. Ross settled at Walton over thirty years ago, and gained a very extensive practice. He was very keen on his work, and a great reader. He loved his practice and his patients, and would always do the best for them. He leaves a widow, three sons, and a daughter. Two of the sons are in the medical profession.

MEDICAL NEWS

The Services

ROYAL NAVY MEDICAL DEPARTMENT
Surgeon Rear-Admiral Guy L. Buckeridge, O.B.E., has been appointed Deputy Director-General of the Medical Department of the Navy, and took over his duties on August 8th in succession to Surgeon Captain C. V. Griffiths, D.S.O.

DEATHS IN THE SERVICES

Major Samuel Butterworth, R.A.M.C. (ret.), died at Portsmouth on May 23rd, aged 76. He was born at Rochdale on June 21st, 1857, and entered the Army as surgeon on August 2nd, 1884. He became surgeon major after twelve years' service, and retired on August 3rd, 1904. He received the Sudan Campaign of 1885, at Suakin, and in the Egyptian medal with the Khedive's bronze star; and in the South African War in 1899-1902, when he took part in operations in Natal, including the relief of Ladysmith, Lombard's Kop, and Colenso, and the relief of Ladysmith, also in the Transvaal and the Orange River Colony, was mentioned in dispatches in the *London Gazette* of February 8th, 1901, and received the Queen's medal with five clasps and the King's medal with two clasps.

Medical News

A clinical meeting of the Paddington Medical Society will be held at the Great Western Royal Hotel, Paddington, W., on Tuesday, August 14th, at 9 p.m.

The next lecture-demonstration arranged by the Fellowship of Medicine and Post-Graduate Medical Association (1, Wimpole Street, W.) will be given by Dr. Clark-Kennedy, at 11, Chandos Street, W., on August 14th, at 2.30 p.m.; the subject will be hysteria. Mr. A. C. Gardner will give a short course of demonstrations on the treatment of fractures at St. George-in-the-East Hospital, Raine Street, E., from August 13th to 17th, at 2.30 p.m. The course will include fractures of the upper extremity, fractures of the spine and pelvis, and fractures of the lower extremity. Daily instruction in various branches of medicine and surgery is provided by the panel of teachers.

At a recent meeting of the council of the Oxford Ophthalmological Congress the following executive appointments were made for 1935: Master, C. G. Russ Wood; Immediate Past-Master, Cyril H. Walker; Deputy Master, Philip H. Adams; Honorary Secretary and Treasurer, F. A. Anderson, 12, St. John's Hill, Shrewsbury. The dates for the next congress are July 4th, 5th, and 6th, 1935.

In the House of Commons, on July 31st, Mr. Elliot, replying to Mr. Joel, said he understood that the scheme for the supply of milk in schools at reduced rates, which was to be submitted by the English Milk Marketing Board for approval under Clause 11 of the Milk Bill, would probably provide that milk should be delivered in bottles wherever possible, and that straws would be provided with the bottles.

The report for 1933 of the pathological laboratories of the gift of the Prudential Assurance Company of the City of London Hospital for Diseases of the Heart and Lungs comprises a summary of the work done and two illustrated reprints of papers published during that year in *Lancet*. The titles of these papers are: "Infracted Phonogram of the Aortic Valve" and "The Morphology and Histology of Atherosclerosis."

A paper on "Recent Tendencies in the Development of General Hospitals in England" in the *Quarterly Bulletin of the Health Organization of the League of Nations*, by Dr. Melville D. MacKenzie, has been published separately in pamphlet form (Vol. III, Extract No. 5).

It is announced that Dr. H. Morley Fletcher and Dr. G. F. Still have been appointed consulting physicians and Mr. O. L. Addison and Mr. George E. Waugh consulting surgeons to the Infants Hospital, Vincent Square, Westminster.

The offices of the National Smoke Abatement Society have been transferred to 36, King Street, Manchester, 2.

Dr. James Marshall, international inside right of the Glasgow Rangers Association Football Club, has been transferred to the Arsenal. Dr. Marshall graduated at Glasgow University in October last, and a condition of the transfer is that he is to continue his medical career in London.

The King has appointed Dr. D. P. Wailling, acting medical officer, to be an Official Member of the Executive Council of the Presidency of the Virginia Islands.

Professor d'Hérèlle has resigned his chair at Yale University for the directorship of the Institute of Infectious Diseases at Tiflis, where he will continue his studies on the bacteriophage.

Professor H. Schottmüller of Hamburg has been elected president of the German Society of Internal Medicine for 1935.

Professor Luigi Devoto, professor of industrial diseases at Milan, Professor Giuseppe Muscatello, professor of clinical surgery at Catania, and Professor Giulio Salvi, professor of human anatomy and rector of the University of Naples, have been elected members of the Italian Senate.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, B.M.A. House, Tavistock Square, W.C.1.**

ORIGINAL ARTICLES and **LETTERS** forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication. Authors desiring **REPRINTS** of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to **ADVERTISEMENTS**, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBER** of the British Medical Association and the *British Medical Journal* is **EUSTON 2111** (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are:

EDITOR OF THE BRITISH MEDICAL JOURNAL, Anthology Westcott, London.
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Anthology Westcott, London.*
MEDICAL SECRETARY, *McLaren Westcott, London.*
The address of the Irish Office of the British Medical Association is 18, Kildare Street, Dublin (telegrams: *Brillias, Dublin*; telephone: *62550 Dublin*), and of the Scottish Office, 7, Drumbooth Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephones: *21361 Edinburgh*).

QUERIES AND ANSWERS

House-fires

"O. M." (London, E.C.) writes in reply to "G. L." (July 7th p. 47). My own experience in recent years of similar plagues of fire occurring on windows of two rooms, one exactly above the other, may help him. Looking round for a possible nesting place, I removed a gas fire from the fire-place of the lower room, a fire which had been only 5 ft. in use for years. I collected over four pint jars of fire (ordinary house variety), having first stuffed them with a spray. This process was repeated to ensure thorough evacuation of all fires and the lower aperture of the chimney stopped up with a paper bung since when no fire have recurred throughout the subsequent season.

Tennis Elbow

In reply to "Wessex" a chartered physician writes: I have even obtained a very satisfactory result with the following treatment: fifteen minutes' moist heat, twenty minutes' treatment with a very hot (140° F.) dry massage of this time to be devoted to local treatment over and around the elbow-joint, and gentle active exercise within the limit of pain. This can be used daily in a natural manner for a short period, say one day under a strain.

LETTERS, NOTES, AND ANSWERS

After the first day it is possible to decide to what extent it may be used in this way without a painful reaction. Any loss of muscular tone may be restored by graduated faradic contractions. There should be a definite improvement at the end of ten days' daily treatment if applied intelligently by an experienced masseur. Otherwise I would suggest considering the possibility of: (1) circulating toxin, as advanced by many authorities; (2) a collection of inflammatory material lying underneath the dense fascia of the extensor muscles over the head of the radius. In conclusion, I might inquire whether "Vessex" is satisfied that his back-hand is an orthodox stroke.

Nail-biting

"W. R. W." (Hove), in answer to the query of "M.B.Ed." for a method of curing nail-biting, writes: I would suggest he should ask the patient's dental surgeon to fix two caps on the upper first permanent molars. These will keep the incisors from meeting, and so prevent the girl biting her nails. The caps must not be left on too long, or the articulation will be upset, but from my own experience in a very bad case the habit is soon cured.

Spermatorrhoea when Bathing

Dr. W. PATERSON BROWN (London), in reply to "M.D., D.P.H." (July 28th, p. 192), writes: The discharge of semen following upon an unusual or inadequate stimulus is to be regarded as a common symptom of perversion or neurosis, and may occur in the apparently healthy. Analytic psychotherapy has benefited many such cases, and cure is usual.

Income Tax**Depreciation of Car**

"H. L. P." has sold a car for £47 10s. which is the exact amount to which the cost had been reduced by the aggregate of the depreciation allowances up to that for the year 1934-5 inclusive. He bought a new car for £218 10s. in June, 1934—the full amount before any deduction for the £47 10s. received for the old car. What depreciation should he claim when making his return for 1935-6?

* £218 10s. at 20 per cent. = £44.

Deduction for Rent and Rates

"CHESHIRE" owns his own house and surgery. What deductions are allowable?

* A good deal must depend on the actual facts—for example, a practitioner possessed of substantial private means might use premises where the professional element was comparatively small. Assuming that "Cheshire" has a surgery and waiting room on the ground floor, and a garage, he might reasonably claim one-half of the rates and income tax assessable value. If there is no separate waiting room he may not succeed in obtaining more than one-third.

Proportion of Household and Car Expenses

"D. C." differs from his local inspector of taxes with regard to the proportion to be applied to expenses which are not entirely professional—for example, house rent, domestic service, private use of car on holidays, etc.

* The difference is mainly one of principle. "D. C." regards the proper professional charge as the amount which the service, etc., would cost, and the inspector considers that the total actual expenditure should be divided in the approximate ratio of professional and private use. The latter is the generally accepted view, and we believe it would be upheld on appeal. It may, for instance, be true that one maid alone would be inadequate to look after the surgery, attend the door, etc., at all times; but if, in fact, two maids are kept—and one, on the average, is fully employed on the domestic work of the house—then only one-half the expense of the two is deductible as a professional expense.

Employment of Wife: Special Allowance

"B. R.'s" bookkeeping, typing, and clerical work generally is done by his wife, who receives £2 a week in consideration of that work.

* He is entitled to the special allowance for wife's earned income of £45 per annum. The £104 can be deducted as a professional expense, but if so must be separately assessed on the wife. Repayment can be obtained in respect of last year, when the claim was omitted.

LETTERS, NOTES, ETC.

Boiled Milk

"E. B." writes from Birmingham: One sees so much in the papers of "Drink more milk," and many doctors say "Drink more milk boiled." It is not generally known that when milk is boiled, if it is immediately well whisked to a froth, either in the saucepan or in the bowl, the boiled flavour disappears, and the tough scum, to which so many invalids and particularly little children object, does not rise to the top. When the milk is cold, if it is passed through a fine sieve a few disintegrated particles of scum may be found, but nothing that would be noticeable when used in an ordinary way. In two or three hours the cream rises, and can be used for tea, coffee, or fruit. Milk prepared in this way has a rich, delicious flavour.

Insect Bites and Iodine

Dr. P. PRINGLE (Uxbridge) writes: In connexion with the case of gangrene of the finger following an insect bite, recorded by Dr. Ibbotson (*Journal*, August 4th, p. 240), I should like to record that I have found in every case of septic insect bite which has presented itself to me this summer a history of the immediate application of iodine. I have wondered if anyone else has any views on this subject.

Magic Pastille

A Birmingham correspondent has sent us a cutting from the advertisement pages of a celebrated weekly periodical. The object of this advertisement is to persuade readers that by eating a pastille every night before going to bed they can smoke as much as ever they like without any ill effects. "It seems to me," writes our correspondent, "a pernicious kind of thing to advertise, for we know that if a man is affected by smoking in the manner suggested in the picture, it is time he began to cut his tobacco down, and realized that no masking of symptoms will do any good."

Medical Golf

The Scottish Medical Golfing Society held its inaugurating meeting at Hadley Wood Golf Club on July 26th, with the greatest success. The prize for the best eighteen holes against bogey, presented by Dr. Skelley, was won by Dr. John Grant. The prizes for the first and second nine holes were won by Dr. Mackenzie and Dr. Findlay. Members dined together at the clubhouse.

Disclaimers

Professor GREY TURNER writes: In a Sunday newspaper, which has a considerable circulation in the North of England, an account recently appeared of a case on which I have lately operated at the Newcastle-on-Tyne Royal Infirmary. Under an arresting title misleading statements were made concerning the operation, and my name was mentioned in a way to which I very much object. Needless to say I knew nothing whatever about the report, nor did I give any information to the newspaper authorities, nor have they obtained information from the report, castle-on-Tyne Infirmary. It has unfortunately become not uncommon in this district for the more sensational papers to write up accounts of cases of which they have heard, and this is the third occasion I have been the victim of publicity during the last twelve months. On a previous occasion I had an interview with an editor, and as a consequence he published a small paragraph in an out-of-the-way part of the paper disclaiming my connexion with the article in question; but evidently they find the practice provides too "good copy" to be discontinued.

Dr. E. HOPEWELL-ASH (London) writes: To avoid misunderstanding, may I say that certain opinions on the subject of drought and "nerves" attributed to "Dr. Edwin Ash of Welbeck Street" by a Sunday newspaper do not in the least represent my views. A disclaimer from me might perhaps be considered unnecessary, as I have not at any time practised in Welbeck Street; but the opinions in question are supposed to be supported by extracts made from a book I wrote some sixteen years ago—*The Problem of Nervous Breakdown*.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 30, 31, 32, 33, 36, and 37 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 34 and 35. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 124.

BRITISH MEDICAL JOURNAL

LONDON: SATURDAY, AUGUST 18th, 1934

THE TREATMENT OF LUPUS VULGARIS*

BY

SVEND LOMHOLT, M.D.

DIRECTOR OF DERMATOLOGICAL CLINIC, FINSEN LIGHT INSTITUTE, COPENHAGEN

Lupus vulgaris does not belong to the common diseases. Stühmer thinks that in Germany the frequency of patients with lupus vulgaris (present or cured) is about 1 per 1,000 inhabitants. The incidence is much the same in Denmark, where from a population of about three millions we receive some 100 new cases each year.

The serious character of the disease is due to the following features: (1) its extremely chronic course—patients who have once contracted lupus hardly ever get rid of it without treatment; (2) the fact that it attacks young persons, spoiling the years of their youth and marking them for the rest of their life; and (3) its localization, in a great majority of cases, to the face, where it produces permanent and markedly disfiguring destruction of tissues, often so extensive that even if the disease itself is cured the tracks it leaves behind are so unsightly as considerably to handicap the patient in obtaining employment.

General Features of the Disease

Lupus, as is well known, may arise in three different ways: (1) By direct inoculation, which is rare and only of slight practical significance, as the lesions produced in this way are generally small, benign, and most often localized to the hands, where they are comparatively easy to cure. (2) By extension, as a rule in one of the following three ways: (a) from suppurating lymphadenitis involving the skin, most often from cervical or pre-auricular lymph glands; (b) from colliquative tuberculosis involving the skin—this is seen most often in children; and (c) around a tuberculous fistula—for example, tuberculous osteitis, arthritis, etc. (3) By haematogenous (or lymphogenous) transplants from tuberculous foci elsewhere in the body (lungs, lymph glands, or mucous membrane of the nose); this latter is by far the most prevalent.

From these facts it obviously follows that the most rational procedure for the prevention of lupus is to combat the spread of tuberculosis as a whole. To this end main stress should be laid on reduction of the number of infection-carrying persons rather than on the treatment of the individual tuberculous patients. It is not persons infected with a clinically serious form of tuberculosis—for example, pulmonary tuberculosis—who develop lupus; on the contrary, these patients seem to be fairly immune.

On going through the data in respect of all new lupus patients admitted to the Finsen Institute during the decade of 1922-31, we have found that out of a total of 787 patients (224 men, 563 women) only twenty-six showed signs of active tuberculosis. Among the remainder, fifty-five showed signs of old tuberculosis.

* By invitation of a Section in the Society of Dermatology at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

eighteen others showed areas of calcification in the hilar glands only, forty-five gave a past history of pleurisy, and a good many (250) had had cervical adenitis. It should be mentioned, however, that x-ray examination has not been made systematically, but only in a comparatively small number of cases, where there was particular reason for doing so. Consequently, it may be that latent tuberculous processes giving no symptoms have been overlooked in a considerable number of cases, though there cannot have been missed many cases of florid phthisis, as nearly all patients were under the closest observation in the hospital.

Prophylaxis.—Tuberculosis prophylaxis has two aspects—human tuberculosis and bovine tuberculosis. In pulmonary tuberculosis 97 per cent. of the cases are due to the human type of tubercle bacilli; and here the prophylactic measures must be isolation and treatment of open infectious cases. In tuberculous adenitis, which in about 80 per cent. of the cases are due to bovine infection, the prophylactic measures must be directed especially at milk control.

As to the aetiology of lupus vulgaris, our investigations at the Institute have demonstrated the infection to be bovine in about 40 per cent. of the cases. Dr. K. A. Jensen of the State Serum Institute, Copenhagen, has been kind enough to type-determine the tubercle bacilli in thirty-one cases of lupus vulgaris. Eighteen showed the human type, twelve the bovine type, and one a dysgonic human type. A particularly striking feature in these findings was the fact that a majority of the isolated strains—twenty-one—showed more or less attenuation of the virulence (ten human, ten bovine, one dysgonic human), whereas only five were found to be of normal virulence (three human, two bovine). In the remaining five strains, all human, the virulence has not yet been determined.

We have not been able to demonstrate any difference between the course of cases of lupus due to infection with the human type and cases due to bovine infection. In combating lupus it is essential, therefore, to have in mind both forms of tuberculosis. It would take too long to enter into the details of this prophylactic work, especially as this work falls largely within the domain of the chest specialist, school medical officer, and district medical officer. It will suffice here to establish that the occurrence of lupus will be automatically reduced to the same extent as tuberculosis in general is reduced.

Light Treatment.—So much for the prophylaxis. Fortunately therapy also enables us to do a great deal in the fight against lupus. In Denmark we estimate that we are able to cure about 80 per cent. of our patients—that is, make them free from symptoms—and to do that so thoroughly that they remain symptom-free for the rest of life, or at any rate for a number of years (vide the statistics of A. Rønn: *Comptes rendus du VIII^e Congrès international de Dermatologie*, Copenhagen, 1931).

1930). Our principal treatment consists in local Finsen treatment with concentrated carbon arc light, supplemented with carbon-arc-light baths. It is a very rare event for a case of lupus to be of so malignant a nature that it is not improved by our light therapy. During thirteen years' experience in the Finsen Institute, Copenhagen, the writer has only seen two such cases. Both were in children; the disease began in the nose and spread steadily in spite of thorough treatment. Lately, however, a new form of light treatment has been introduced, and it seems to be able to check the disease even in these two cases. Generally lupus is very amenable to Finsen light treatment, recovery being obtained in the great majority of the cases, and a considerable improvement in the remainder. In early cases with small lesions the percentage of recovery is practically 100. Consequently all efforts must be made to bring the patients under light treatment early in the disease, especially as a temporary symptomatic treatment (corrosives, cauterization, etc.), such as is often given by physicians anxious to render immediate help, may make light treatment difficult because the scars formed hinder the penetration of the light.

To ensure that patients come early under the Finsen light method of treatment it is essential to provide sufficient adequately equipped hospitals for such treatment. In Denmark, with its three million inhabitants, the Finsen Light Institute has been found to afford ample accommodation. It has for this special purpose about fifty beds, twelve lamps of the Finsen-Lomholt type, and a similar number of carbon-arc-light baths—that is, six light baths for the daily treatment of about sixty patients for one hour each. The Institute can receive nearly all the fresh cases of lupus referred to it, can carry on the treatment to relative recovery, and can also manage the treatment of a not inconsiderable number of older patients whose earlier treatment has not resulted in complete recovery. We have been able to cure several of these latter patients as well, and in the rest we have obtained a definite improvement.

Working of "Light Stations."—Assuming that the frequency of lupus vulgaris is relatively the same in Great Britain as in Denmark, Britain would require about ten stations of a similar size to the Finsen Institute to combat the disease effectively. In the establishment of stations for treatment of lupus it is an indispensable condition that each station must have as medical superintendent an experienced and interested dermatologist to manage the treatment, and, in addition, a capable rhinologist to assist him. It is also important that the individual stations should not be too small. Each station should be large enough to collect sufficient clinical experience to ensure that in it diagnosis and treatment may be efficient. The therapeutic results achieved by these stations provide the best incentive to lupus patients to present themselves for treatment. For reasons not altogether accountable, most—or nearly all—lupus patients belong to the poor classes, and they are apt to lose courage if the first treatment to which they submit themselves does not give definite results. With their disfigured features they are so reserved that they do not even reappear in the clinic; but, with the better prospects of cure offered by the light treatment, they come so freely that it may even be necessary to select the cases most suitable for treatment—that is, cases in which there are prospects of complete recovery. It may even be necessary temporarily to turn away cases with particularly extensive lesions (mostly elderly persons) because they would require too much time and occupy the apparatus too long in relation to the possible result obtainable, and so hinder the treatment of younger patients with less extensive lesions.

The close co-operation of the general practitioner and dermatologist is of great importance to the success of the work of the stations. In instruction of dermatology at the medical school particular stress ought to be laid on the mention of lupus vulgaris. Lupus vulgaris, like tertiary syphilis, is a disease that is very frequently wrongly diagnosed, especially in its earlier stages, when the treatment is easy and gives most promise. It must be impressed upon the medical students that in dealing with any protracted stationary affection of the face they must always keep in mind the possibility of this disease, and, in case of the least suspicion, apply to an experienced colleague for assistance in diagnosis and treatment. As mentioned before, lupus is particularly frequent in the poorest classes of the population, perhaps partly because the disfiguring disease precludes these unfortunate persons from all chance of employment. The lupus stations must therefore co-operate with the physicians attached to institutions for the poor and disabled, with the medical district officers, with school medical officers and physicians attached to institutions for the care of children suffering from surgical tuberculosis. Lupus is of rare occurrence in sanatoria for adults with pulmonary tuberculosis. It is also important to arouse the interest of nurses engaged in charity work, municipal nursing, tuberculosis stations, etc. Most lupus patients have no regular family physician to consult, neither do they belong to sick benefit clubs, and the charity nurses should be informed as to the existence of chronic lupus patients in need of treatment.

There are two forms of treatment—general and local—and our experience shows that the local treatment is still the most efficient of the two, although the general treatment is also of importance.

General Treatment

1. *Dietetic Measures.*—In recent years, particularly in Germany, extensive experiments have been made with certain forms of diet (Gerson, Hermannsdorffer-Sauerbrück) which contain a large amount of vitamins and fresh vegetables, and practically no sodium chloride at all. Some authors have reported very good symptomatic results from this treatment, although real cure appears to be considerably less frequent. The results reported by other authors have been more modest.

In the Finsen Institute, experimental treatment with this diet was given to forty patients, but without any noticeable effect. When the patients themselves were asked what was their personal impression only one replied that he had noticed any considerable improvement. Six thought there was some improvement, but the rest had noticed no change at all, or at the most only a very slight improvement. It is difficult to give any explanation of this, but possibly it is connected with the diet of the patients prior to their admission for dietetic treatment. Often the food of poor people is very monotonous, and it is particularly poor in green vegetables and vitamins, the importance of which for the resistance of the organism to infections has been demonstrated clearly in recent years. It is easy to understand that the condition of such patients improves when they are placed on a more suitable diet, but this does not warrant the diet being regarded as a specific remedy against tuberculosis, or assuming that a change in diet would be sufficient to effect complete recovery.

In view of these experiences, however, we have in recent years given many of our patients supplementary food rich in vitamins in addition to the ordinary diet—particularly in cases with extensive processes of lupus vulgaris, where the general condition of the patient was debilitated. This supplementary vitamin food consisted of vitamin A (50 grams butter and two carrots), vitamins

B and E (two tablespoonfuls of wheat germ), and vitamin C (the juice of a lemon). With this diet we have obtained a considerably greater increase of weight in our patients than usual (about double).

2. *Light Baths.*—Finsen was the first to observe that sun baths had an excellent effect on surgical tuberculosis. Unfortunately the climate in Denmark does not permit of an extensive treatment with sun baths, but the idea rapidly gained ground in other countries, especially in Switzerland (Bernhard, Rollier), where it gave excellent results. Later Reyn introduced a similar treatment with artificial light: the Finsen carbon-arc-light bath, given as a supplement to the classical local Finsen treatment of lupus with concentrated carbon arc light. By this the therapeutic results in the Finsen Institute were improved considerably, and this combination of local and universal light treatment still remains the routine treatment in our Institute. It is our experience that the carbon arc light has a much stronger effect on lupus vulgaris than the mercury lamp. In recent years we have commenced to introduce a new type of lamp, the "universal lamp" in which the pure carbons are replaced by Siemens's Schneeweisskohlen ("white flame carbons"), which give an emission resembling sunlight considerably more closely than does the emission from pure carbons. The carbons are placed almost parallel, so that the emission from both craters is utilized when the patients are irradiated in a horizontal position with the lamp suspended above them. With this lamp we obtain a much stronger erythema effect than previously, and the same, or even a better, therapeutic effect with a shorter time of exposure. Of course it is difficult to furnish any statistical proof of this, but several patients in whom the improvement seemed to have stopped under the original carbon-arc-light treatment made new progress with the new light baths. This was the case with the two before-mentioned cases which, as stated, proved refractory to the original treatment with the Finsen light bath.

The light baths are to be given to the patients lying down, daily or every other day, in such initial doses as will produce a moderate erythema. The time of exposure is increased gradually from day to day, up to one hour as a maximum, care being taken to avoid a strong erythema uncomfortable to the patient. In case of strong irritation it is advisable to make a short pause, and then begin anew with a smaller dose. The treatment should not be continued uninterruptedly for more than three months at the most, after which period there should be a pause for about one month. Then the light baths may be given again. We have never seen any injurious effects from our light baths, and this applies also to patients suffering from a simultaneous pulmonary tuberculosis. In pulmonary cases, however, greater caution is advisable so as to avoid any exhaustion of the patients by a too energetic treatment. In favourable cases complete recovery of lupus may be obtained by treatment with carbon-arc-light baths alone, as has been demonstrated previously by Heiberg and With. Not long ago I had occasion myself to make sure of this in one case, in a Swedish patient with an enormous plaque of lupus vulgaris on the face and numerous smaller lupus nodules on the legs—so many that it would have taken much too long a time to give local treatment. The lupus processes on the legs subsided almost completely under the light bath treatment. Subsequent histological examination of two small lupus lesions showed no sign of tuberculous granulation tissue.

Local Treatment

Local treatment is still the most important form of therapy, and comprises several highly effective methods.

1. *Surgical Removal.*—Excision is the most sure and, if successful, the simplest method. It may be employed for very small lupus lesions on the face—though not very well where a lesion is located on the nose—and on the hands, and against most lupus processes on the trunk and extremities. The excision must include also a surrounding zone of definitely normal tissue. The result will most often be complete recovery, although recurrence is not altogether rare. To ensure a neat scar formation, and particularly when there is a tendency to hypertrophy of the scar, we give the patient an after-treatment with radium emanation of about 0.04 millicuries per square centimetre, applied in thin wax plates for a period of about sixteen hours at a time, and altogether four or five times at intervals of four weeks. Simple removal of the lupus process by scraping with a curette never leads to recovery, and should therefore never be resorted to.

2. *Electrocoagulation.*—In recent years this treatment has been largely recommended, especially by German authors. It has the advantage that the risk of recurrence is less than with a simple excision; on the other hand, the scars are not quite so neat after electrocoagulation as after excision. The treatment may be carried out either by compact destruction of the entire area involved—the method of choice with all small lesions—or by regular excision with a knife-shaped electrode or a bent band-shaped electrode, as recommended by Wucherpfennig (*Über das elektrische Schneiden mit der Drahtschlinge*, Jena, 1932). The open wounds are allowed to fill in by granulation, or their edges are pulled together by sutures. This method is quick and radical, and often gives fairly good results, but it must be clear that it is not an ideal method, as it often produces disfiguring scars. We have therefore refrained from its employment in most recent cases. In these we always prefer the light. On the other hand, we employ electrocoagulation a great deal in small local relapses in light-treated tissue that are found resistant to repeated treatment with light. After removal of the lupus lesion with electrocoagulation we often repeat the light treatment, and we have had quite satisfactory results from this combination.

3. *Scarification.*—This form of treatment has been recommended, especially by French authors. We have had no personal experience with this method in our Institute, but it does not appear to be very effective.

4. *Chemical Corrosion.*—The sovereign caustic for this purpose is pyrogallie acid, which Veil proved to have an elective caustic effect on tuberculous granulation tissue. It is most efficacious when combined with salicylic acid and resorcin (vaseline, 11 parts; pyrogallie acid, 3; salicylic acid, 3; and resorcin, 3). This is a very powerful caustic ointment, but a satisfactory effect may be obtained also with somewhat weaker concentrations.

The procedure is as follows. The ointment is smeared on a piece of lint cut to fit the plaque to be treated and fastened by a tight bandage. The bandage is changed in the morning and in the evening, and each time as much of the destroyed tissue as possible is cautiously removed. The treatment may be rather painful, and as a rule is only tolerated for a few days at a time. When the treatment is discontinued the caustic ointment is replaced by an indifferent soft ointment, or by a compress of 0.2 per cent. resorcin solution.

Corrosive treatment is able to remove the main part of lupus tissue, even in large plaques, but complete recovery is rare. After some time new nodules make their appearance in the zone around the scar and in the scar itself. Further, the scar is apt to undergo hypertrophy and become rather disfiguring. A serious drawback to the corrosive treatment is that the massive scar tissue makes subsequent light treatment very difficult. If there is

any chance of having the patients treated with light one should not waste any time on a protracted corrosive treatment under which there may be heavy scar formation. On the other hand, pyrogallol ointment may be employed with great advantage as a preliminary to light treatment in cases with extensive proliferating lupus plaques, removing rapidly and readily the main bulk of lupus tissue. But the local Finsen treatment should always be instituted immediately after. Corrosive treatment is indispensable in dealing with the verrucous form of lupus on the hands, being excellent for removal of the keratotic surface of the lesion, which it is hard for the light to penetrate.

In England much use is made of a special remedy—liquor hydrargyri nitratis acidi, B.P., 1913. The solution is applied cautiously to the individual lupus nodules by means of a small cotton swab, and it is left on for a few minutes so that it produces a local corrosion. We have not had any personal experience with this treatment in lupus, but we employ the same remedy largely in the treatment of tuberculous abscesses and fistulas. In these conditions it is highly efficacious, superior to all other remedies.

5. Local Light Treatment.—There are two methods for local light treatment. The Finsen treatment with concentrated carbon arc light, and the Kromayer treatment with water-cooled mercury vapour light. The latter method of treatment is by far the easier and less expensive, but it is the general consensus of opinion that it is considerably inferior to the Finsen treatment, and therefore it ought to be employed only where Finsen treatment is not available.

For Finsen treatment, as carried out at the Finsen Institute, we now use exclusively our new model of the Finsen-Lomholt lamp, which has the advantage of being worked automatically, so that one nurse can operate three lamps at a time. This lamp, also, is considerably more effective than the original model. Its main points are as follows (for details see *British Journal of Dermatology*, 1930).

I. A carbon arc lamp of 20 to 30 amperes, with automatic regulation, and with the positive upper carbon in the horizontal and the negative carbon in the vertical position.

II. A concentration apparatus consisting of: (1) a strong plano-convex front lens (focus distance about 10 cm.); (2) a large quartz cylinder, the ends of which are formed by two plano-convex lenses melted into the walls of the cylinder, the cylinder being filled with a watery solution of cobalt sulphate (red); and (3) a cuvette filled with a blue solution of copper sulphate in strong ammonia, a strong plano-convex quartz lens forming the front side of the cuvette.

III. A number of quartz tubes of different shapes, to be used for the compression of the lupus patch during the treatment.

By using lenses of thermo-resistant quartz (fused instead of natural silica) it is practicable to place the luminous positive crater close to the concentration apparatus, and the use of coloured filters makes it possible at the same time to filter off the inactive luminous rays. By this the concentration of the ultra-violet rays is increased to four or five times the concentration obtained with the original apparatus, so that the irradiation time may be reduced to about one-third of the time formerly required. Thus one nurse can easily treat nine patients in the same time that it previously took to treat a single patient. This naturally means a saving of time and money, and, in addition, the effect is stronger and more constant. Using carbon with a nickel core, a greater therapeutic effect is obtained, because it gives a considerably stronger emission in that part of the ultra-violet field which appears to be of particular importance for this therapeutic effect. This is in the field from 3,300 to 3,600 A.U. It is essential to clean the lupus lesion very carefully and cautiously before the treatment, removing all scales, crusts, and remnants of ointment, but avoiding any

bleeding. A front piece is chosen which corresponds in size and form to the lupus area which is to be irradiated, but the treatment must always include also a zone (about 5 mm. wide) of the adjacent healthy tissue. The compression apparatus is adjusted to give a firm, fairly strong pressure, so as to cause an effective degree of anaemia in the area in question. Experiments on rabbits' ears have shown that this is essential in order to obtain a good deep effect. Yet the treatment need never be painful to the patient, and ought not to be so. Only in rare cases with extensive open lesions may it be necessary to employ some local anaesthetic (2 to 4 per cent. cocaine or percaïne solution).

The treatment must be given in an orderly manner, beginning at one side of the lesion and proceeding systematically until the whole plaque is treated completely. The physician in charge must follow the treatment from day to day, and direct what parts are to be treated and in what succession; he must watch especially that one application joins another closely, so that no diseased tissue is missed. As a rule the nose is the first area to be treated, beginning with the vestibule when this is involved, as the treatment of this part will be painful if sensitive reactions are already brought about on the outside of the nose by preceding treatment. Similar rules apply to treatment of the inner surface of the lips. It goes without saying that the treatment of these parts should be carried out in co-operation with the rhino-laryngologist. In the case of an extensive lupus plaque involving both halves of the face the treatment must be managed so that the patient is able to rest comfortably on one side at night. A lasting good result can be obtained without pain. On the other hand, it is only natural, for the patient's own sake, to make the treatment as intensive as possible. Occasionally it is advisable to cut down the irradiation time to three-quarters or half an hour—for instance, when the lesion is very extensive, or when the patient has been treated previously with x rays, after which the skin reaction is always particularly strong and painful, and slow in healing.

The power of the current should as a rule be kept steadily at about 25 to 30 amperes. With this there are no difficulties with the usual front pieces. It happens now and then, however, that the patient complains of secondary pains from the reaction set up by the treatment in the large open plaques. If very intensive treatment is essential, such pains are unavoidable. These pains are never very severe, though they may weary the patient by being so protracted, but as a rule careful bandaging will reduce them to a minimum. The great majority of our patients do not complain of pain at all.

Results of Light Treatment

To obtain rapid healing it is very important strictly to carry through a suitable treatment for the reactions that appear after irradiation. They heal fairly rapidly—in eight to fourteen days—when treated with moist compresses—for example, 0.2 per cent. resorcin solution. The compress consists of three to four layers of lint, cut exactly to the shape of the inflamed area, soaked with the solution, and wrung so hard that they remain only a little moist; they are then covered with waterproof material or with a piece of lint smeared with ointment. The dressing is changed at least three times daily. If it is not practicable to change the dressing so often it will be preferable to apply an ointment bandage—for example, vaseline 40 parts, adip. lanae hydrat. 50, zinc. oxid. 10. In secondary infection an antiseptic—for example, precipitate of mercury 2 per cent.—is added. Silver nitrate is not to be used on account of the colour, neither in solution nor for ointment. Occasionally it

may be advantageous to use compress bandage and ointment bandage alternately, or to change from one to the other, according to what is most agreeable to the patient. In only quite exceptional cases will it be necessary to employ a local anaesthetic (cocaine, percaine).

If the lupus plaque is ulcerated to begin with the ulcerated places must be treated directly. If the irradiation produces distinct haemorrhage the treatment of this area must be discontinued until the blood has been absorbed, as free blood in the tissue cannot be made to disappear by compression, and the ultra-violet rays are absorbed by haemoglobin. As a rule the treatment may be repeated after one to two weeks. *In lupus of recent development our rule is always to give five to seven series of irradiations with an interval of eight to fourteen days as first treatment.* Each series consists of a number of exposures lasting one hour and covering an area the size of, say, a shilling, until the whole patch has been irradiated. This will in most cases give complete recovery. In several cases we have seen healing after only three to four irradiations, but as it is exceedingly important to obtain complete recovery with the first treatment, five to seven treatments should be the normal. In the case of compact processes in which the lupus granulation tissue is particularly refractory to treatment, more applications are required. Relapses are more difficult to cure, because the rays have to pass through the scars formed after the previous affection and by the light treatment given.

It cannot be emphasized strongly enough how important it is to complete the treatment the first time. In most of the cases in which we have obtained a lasting cure recovery was obtained with the first treatment. The consequence of this is that in circumstances where a sufficient number of apparatuses are not available, the suitable cases must be carefully selected and treated thoroughly and completely before others are taken on. It is the worst economy imaginable to institute treatment on many cases which can be only half carried through, so that one has to fight in the following years with troublesome and persistent relapses. It is costly and burdensome both to doctor and to patient.

The Finsen treatment may very well be carried through on out-patients. It is advisable, however, if possible, to admit to hospital patients with extensive lesions, especially if their general condition is poor. Only in a hospital is it practicable to ensure a perfectly effective treatment of such patients, for it is difficult to have large areas of light reactions treated properly outside the hospital. Where less extensive lesions require general treatment, such, for instance, as light baths, the patients should be admitted to hospital unless they live so near to the clinic that they can easily attend for treatment every day or every other day. In cases of small benign lesions, where the chief requirement is local treatment, it is best to admit the patients to the clinic for one or two days at intervals of two to three weeks. It is fortunately not essential that a lupus patient should be treated in an extensively equipped modern hospital, as only few lupus patients suffer from severe progressive tuberculosis. For rational and effective combating of lupus vulgaris it is of the very greatest importance that the patients should, through energetic propaganda, be made to apply for treatment in the very earliest stage of the disease, and should afterwards be kept steadily under close observation by re-examination two or three times a year, so that any relapse that may appear can be treated effectively at once.

Treatment of Lupus of Mucous Membrane

With the original treatment of lupus vulgaris the most difficult point was undoubtedly the treatment of

lesions of the vestibule of the nose. This frequent localization, which is often the starting-point of relapses on the outside of the soft part of the nose, was previously treated by means of a quartz prism, constructed by K. K. Lundsgaard, through which the light was reflected on to the mucous membrane. But the effect of this treatment was often uncertain, because it was difficult to fix the prism apparatus in the proper position. Furthermore, the effect was always very weak, because the effective utilization of the rays was only slight—10 per cent. maximum. Even with an uninterrupted radiation lasting four hours the reaction was often quite weak.

The new apparatus produced much better results from this part of the treatment. The front piece to be used for the treatment of the vestibules is somewhat longer and more pointed than the forms used for skin treatment. The little surface which is to lie on the lesion is made oblique, and this gives an apparatus which may be introduced into the vestibule quite easily, and is readily adjusted to the surface of the mucous membrane by firm pressure on the outside of the nose, easily maintained by the patient himself during the treatment. With the new apparatus the intensity of the radiation was multiplied. It is possible within fifteen to twenty minutes to get a constant and much stronger effect than could be obtained previously in four hours. The vestibular lupus was previously extremely difficult to cure, but now the cure is always easy.

A longer and more slender model was constructed for use in the depth of the oral cavity, and even on the posterior wall of the fauces, but this required a modification of the concentration apparatus in order to obtain a longer focal distance. Through intimate co-operation with the oto-rhinologist of our Institute, Dr. Ove Strandberg, we have been able in the last year to treat some cases of lupus of the gums and fauces—some of them very extensive lesions—and we have obtained a considerable improvement, even clinical recovery, in cases which had previously been intractable.

The above-mentioned front pieces are also very serviceable in the treatment of lupus of the inner surface of the eyelids. Here, of course, it is essential to protect the cornea carefully from the light rays, and a very simple way of doing this is to wrap the front piece in several layers of gutta serena paper.

Radium and X-Ray Treatment

Radium and x rays have been widely used in the treatment of lupus vulgaris. They give a good transitory, symptomatic effect on the patch, but a definite cure is rare, and the result will after some years generally become that of a disfiguring atrophy with the well-known telangiectasia, irregular pigmentation, and even ulceration; not to mention the marked tendency to malignant degeneration. Very unfortunate is the difficulty created by this atrophy and reduced vitality of the skin for the treating of relapses of lupus vulgaris in the atrophic scar with light. The treatment becomes very painful, and the reactions after the light treatment heal but slowly—in months instead of weeks. The new Grenzstrahlen seem less dangerous than radium and x rays, but a definite cure seems by their means equally difficult to obtain.

Conclusion

According to the scheme outlined above we have treated about 150 fresh cases of lupus vulgaris in the Finsen Institute, Copenhagen, during the last two years. Apart from a few extensive inveterate cases in patients who could not afford sufficient time for proper treatment, we have obtained apparent cure in nearly 80 per cent.—that is, all nodules and other symptoms of activity disappeared,

and the scars remained free from relapses. In the rest of the cases great improvement was obtained. Only a few scattered nodules reappeared in a scar otherwise free from lupus. Probably a repetition of the light treatment, combined perhaps with electrocoagulation, will succeed in removing in these cases, too, the last remnant of the disease, as was in fact found with a number of other inveterate cases which had proved refractory to previous treatment with the original Finsen apparatus.

The two outstanding advantages of the Finsen treatment are its efficacy, and even more the ideal cosmetic results: soft, smooth, often hardly visible scars, which have preserved the full vitality and resistance of the natural skin without any disposition to atrophy, ulceration, or malignant degeneration.

THE EYES AS A CAUSE OF HEADACHE*

BY

ARTHUR GRIFFITH, M.B., F.R.C.S.

SENIOR SURGEON, ROYAL EYE HOSPITAL; SENIOR OPHTHALMIC SURGEON, WESTMINSTER HOSPITAL

It is surprising to an ophthalmologist that physicians attach relatively so little importance to the eyes as a cause of headache. I have examined my notes of 1,000 private cases, and I find that 24 per cent. of the patients came to me complaining of headache. Not every headache, however, is due to use of the eyes, and the oculist, faced with a patient complaining of headache, must determine, if he can, whether the headache is an ocular one or not. In this he may be greatly helped by the history which he obtains from the patient.

First, as to the *situation* of the pain. Usually an ocular headache is frontal or orbital ("pain behind the eyes"); more rarely is it occipital or temporal, and almost never is it vertical. In the series of cases which I analysed, of 181 cases where the type of headache was noted 60 per cent. were frontal or orbital. Next the *time of onset* of the pain should be ascertained. Next the *monon* with ocular headache the pain comes on in the late afternoon or early evening—that is, at the end of a day's work. Sometimes a headache is present on waking in the morning, and it may be difficult to persuade the patient that this morning headache has been earned by the misuse of the eyes on the preceding day. Of course, other headaches may be earned overnight, such as that which comes out of a whisky bottle, but the patient always recognizes this type, and will say that if he ever gets a headache he knows to what to attribute it. The delayed headache is probably due to the power of the healthy human being to ignore slight pain. It is only when he is tired, or when his control has been weakened by sleep, that he becomes conscious of pain. Sometimes patients will say that if, for any reason, they wake in the night, they find they have a headache. Another instance of delayed pain is the week-end headache; the patient may be free from pain during the week, but on Sunday, although using his eyes less, he gets headache. One patient said that he had not time for a headache during the week. Association of the pain with use of the eyes may be so clear as to make it reasonably certain that we are dealing with ocular headache.

Ciliary Muscle Contraction as Cause of Headache

Although the pain of eye headache may radiate through any of the branches of the trigeminal nerve, the initial

cause is painful contraction of muscle. The muscles concerned may be the ciliary muscles, the extrinsic eye muscles, or the occipito-frontalis. If one doubts that contraction of the ciliary muscle can be painful one should put strong eserine drops into an eye; the resulting pain may be severe enough to cause nausea.

The simplest case of pain from ciliary muscle contraction is that of a hypermetrope with equal errors in the two eyes. Such a patient can only see clearly by contracting the ciliary muscles, and throughout his waking day they are in a state of tonic contraction, the contraction being greater when close work is done. After prolonged close work these muscles tire, and the patient finds his sight varying, the type appearing alternately clear and confused. He may seek relief from this by stopping his work and gazing into the distance for some minutes, when he finds that he can continue to focus his work for a time. More frequently he discovers that by getting closer to his work, and so obtaining larger retinal images, he can appreciate it, in spite of confusion of vision, with less mental effort, but this diminution of mental effort is gained at the expense of accommodation and convergence, and a vicious circle is set up, which ends in headache or in breakdown of accommodation. Most children are guilty of the mental laziness which makes them read at too short a distance and so gain larger retinal images. The habit is accentuated by refraction errors and by imperfect lighting, and is one which should be combated constantly by teachers and parents.

When the hypermetropia is of different degrees in the two eyes the ciliary muscles are presented with a more difficult task. Not only must the patient accommodate in order to see clearly, but he must accommodate to a different extent in the two eyes. Patients will often tolerate a considerable under-correction of their hypermetropia or presbyopia better than a small imbalance of accommodative effort in the two eyes. In correcting refraction errors it is of the greatest importance to get the two eyes balancing in this respect.

In astigmatism there is introduced another abnormality of ciliary muscle contraction. If there is much astigmatism the ciliary muscle may make little or no effort to correct it, and there is no "eye-strain" and no headache. But if the degree of astigmatism is low or moderate the ciliary muscle contracts irregularly, more in some fibres than in those at right angles to them, and produces a lental astigmatism of opposite sense to the corneal astigmatism. Often enough the effort is overdone, and we find that a patient who, for instance, has a low degree of astigmatism "with the rule," chooses a cylinder "against the rule." Low degrees of astigmatism often cause more severe headache than do high degrees, although the importance of correcting very small refraction errors has been exaggerated.

More debatable is the question of "eye-strain" and headache being caused by contraction of the iris muscles. It is undoubted that the early cinema theatres were more productive of "cinema headache" than are the modern ones. Much of the improvement may be attributed to abolition of flicker and to reduction in the size of the screen, but another factor is that, whereas in modern cinema theatres a certain amount of general illumination is kept, in the old theatres the house was quite dark. Alternate gazing at the brilliantly lit screen and into surrounding blackness caused alternate contraction and dilatation of the pupils, and this may well have contributed to "cinema headache." In some of the newest cinemas the audience must traverse long corridors before reaching the theatre. One may be inclined to attribute this to love of display on the part of the management, or to ineptitude on the part of the architect, unless one observes that the illumination is gradually reduced as

* Read in opening a discussion in the Section of Ophthalmology at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

one passes from the brilliantly lit foyer to the dimly lit theatre.

Before leaving the subject of ciliary muscle headaches I would refer to the fairly large group of composite headaches in which the ocular part is only a fraction of the whole cause.

As an instance, I would quote the case of a woman who consulted me for very severe and constant headache, which completely incapacitated her. She was taking enormous quantities of barbitone drugs with little relief. She had given up her work, and friends had taken her away on their yacht to try to improve her health, but she spent the whole time in bed, and returned as bad as ever. I corrected her refraction errors and ordered glasses. On wearing them she was free from headache for the unprecedented period of three weeks. Then began a clear association of the headache with her menstrual periods; it returned a day or two before the onset of the period, passed off, and returned for three or four days after the period. I sent the patient to a physician, who treated her with appropriate endocrine preparations, with the result that she has hardly had a headache in over five years.

Headaches Due to Extrinsic Muscle Abnormalities

Here in Bournemouth, where Maddox lived and worked for over thirty years, it is appropriate to discuss the use of prisms. Headache caused by imperfect muscle balance can often be relieved by the discriminating use of prisms, but few things require greater judgement than their prescription. Even more than in correcting refraction errors must one avoid the error of over-correction. It is better not to order prisms than to order too strong ones. Not always can the same prisms be worn for distance and for near work. An esotrope with muscle imbalance sufficient to cause confusion and even diplopia in the distance may find his latent convergence rather a help in reading. Such a person, however, is liable to fall into the habit—a habit which is responsible for much ocular headache—of reading at too short a distance, and so overtaxing his accommodation.

The movements of elevation and depression of the eyes are performed by a mechanism more complex than that used for the lateral movements, and it is perhaps for this reason that vertical heterophorias, although less common than lateral imbalance, are more productive of discomfort and headache; it is especially these vertical errors which call for relief by prisms. As a rule, it is the less good eye which tends to deviate upwards, probably because the elevating muscles are stronger than the depressors. The factor which decides which eye shall tend to deviate is usually the refraction, the eye with the more complicated refraction error tending to rise. When there is little difference in refraction the hyperphoric eye is usually that which is not the "master eye": one might call it the "servant eye." We are therefore correct in speaking, as we usually do, of a right or left hyperphoria, and not of hypophoria.

As rough rules for the prescription of prisms for heterophoria Maddox suggested as maximal corrections two-thirds of the error in esophoria, one-half in exophoria, and two-thirds in hyperphoria. There can, however, be no fixed rules, and each case must be considered separately. A plan which I have found of the greatest value is to make the patient gaze at a distant spot of light with coloured glasses before his eyes, red glass before the right eye and green before the left. If he says, whatever the finding with the Maddox rod may have been, that the red and green lights are mixed together, his heterophoria does not need correction by prisms. If, on the other hand, he sees the red and the green lights separate, one must find the weakest prism which will enable him to mix them. This prism is to be regarded as a maximum, which is not to be exceeded in the prescription. It may even be found that some still weaker prism will give the patient comfort when reading the test types with

both eyes, making the letters appear steady instead of dancing and confused. In prescribing prisms, as in correcting refraction errors, over-correction must be avoided.

It is said that the prescription of prisms for heterophoria is purely palliative and not curative, but this is not always true. It is true that patients who have been relieved by wearing prisms may, when they return a year or so later, be found to have more heterophoria than before, but one finds at least as frequently that the tired muscles have recovered some of their tone, and that we can reduce or abandon the prisms in the glasses.

Occipital Headache

The last group of eye headaches to which I will refer includes those which can often be relieved by the volition of the patient. Many patients suffering from eye-strain screw their lids together. This may be done, as in cases of myopia, to cut off diffusion circles by narrowing the palpebral fissures, but in other cases it would seem that the excessive innervation of the eye muscles overflows into the orbicularis muscles. The frontales muscles are inserted into the upper lids, and they participate in the contraction, and as the frontales, on contracting, pull on the epicranial fascia the occipital muscles are pulled upon, and these, too, contract and cause occipital pain. This is not the only, nor perhaps the commonest, form of occipital headache. We shall hear from the neurologists of occipital pain arising in the meningeal branches of the trigeminal nerve and associated with changes in the meningeal vessels or with alterations in intracranial pressure. In a recent case of Lindau's disease, in which I had been observing the angiomatosis of the retina, the first and only indication that the patient had developed a haemangioma of the cerebellum was the sudden appearance of severe occipital neuralgia.

The occipital headache of eye-strain, however, seems clearly to be localized to the occipital muscles, and to be relieved by pressing on them. It is a form of headache which is easily relieved by wearing suitable glasses. Much may be done for the patient by explaining to him that he is himself producing headache by screwing his lids and frowning, and that he must make himself conscious of the occasions on which he does these things and decide not to do them.

I have intentionally omitted reference to the headache of gross eye disease, such as iritis and glaucoma, of nasal sinusitis, and also of nephritis, cerebral tumour, and hyperpiasis, diseases in which ophthalmologists are interested by reason of the fundus changes which occur in them. I have confined myself to consideration of the headaches caused by misuse of the eyes, and of the ways in which we can relieve them.

A memorial fund to the late Madame Marie Curie has been opened by the hospital in Hampstead which bears her name and operates as a centre for the radium treatment of cancer in women. The appeal is being simultaneously launched in Paris and Warsaw. It has been thought fitting that the money thus received should be most appropriately expended on extension of this hospital in which she was so deeply interested. A department for deep x-ray therapy has recently been added to supplement radium treatment and for certain cases which respond better to x rays alone. Already it is overtaxed, and many would-be patients have to be turned away owing to the lack of facilities. The growing number of applicants, and the fact that for most of these radiotherapy offers the only prospect of relief and cure, make it urgent that the contemplated extension should be undertaken as soon as possible, especially since the establishment of this institution was one of the tributes this great investigator appreciated most highly during her life. Contributions may be forwarded to the treasurer, Marie Curie Hospital, 2, Fitzjohn's Avenue, N.W.3.

HEADACHES IN RELATION TO OCULAR CONDITIONS*

BY

WILFRED HARRIS, M.D., F.R.C.P.

PHYSICIAN TO THE DEPARTMENT OF NERVOUS DISEASES AND LECTURER
ON NEUROLOGY, ST. MARY'S HOSPITAL, LONDON

Headache, one of the commonest of symptoms, is one whose pathology is very doubtful and difficult to explain. The variety of its causes is almost innumerable, and, though many forms of it may be expressed as reflex neuralgias, in terms of the fifth nerve or other nerves supplying the scalp or cranium, yet it is difficult to be certain of the mechanism of headache in a great number of cases.

Pressure Headaches

It has been usual in the past to ascribe headache due to rise of intracranial pressures and migraine as the result of influences such as pressure acting upon the recurrent meningeal branches of the trigeminal nerve, which supply the dura in the various fossae and the falk. Yet we are met by the fact that quite large areas of the dura appear to be insensitive to surgical manipulation in decompressions done under a local anaesthetic. Surgeons tell me that the areas of dura which are specially sensitive are those in the neighbourhood of the larger vessels and of the chief sulci. Opinions vary as to whether the sympathetic supply of pia-arachnoid vessels has any bearing on the conduction of sensations. On the whole, modern physiological opinion is against the sympathetic system being a carrier of sensory impressions, but some authors assert definitely that pain may be conducted along the sympathetic.

There seems no doubt that a sudden rise of intracranial pressure may be a cause of violent headache. This may be due to sudden out-pouring of blood from a subarachnoid haemorrhage at the base of the brain, and I have known this condition commence with sudden, violent pain at the back of the head. This is understandable, owing to interference with, and pressure upon, the meningeal trigeminal branches of the dura in the neighbourhood. In some of these cases subhyaloid haemorrhages may be seen as evidence of the spread of blood along the base to the back of the eye. Violent headache may, however, be produced by distension of the ventricles, and it is a symptom that comes on extremely rapidly from blockage of the foramen of Monro in cases of ependymal tumour in the ventricle. In this case the cerebro-spinal fluid escape through the foramen is obstructed and the pressure within the ventricle rapidly rises as the fluid is secreted from the choroid plexus.

General distension would cause pressure to be transmitted through the cerebral substance, and compress the cortex and the membranes against the vault of the skull, and also at the base, but it is a question whether the severe headache that is felt as a symptom is due to pressure upon the meningeal nerves on the surface or whether it is produced by the effects of the pressure on certain parts of the brain itself—for example, the thalamus, which is in such close relationship with the lateral ventricle.

Migraine

A common cerebral cause of headache, which has close associations with ocular conditions, is migraine. Here, in a typical case, the first onset of the scintillating scotoma, or hemianopia, will be succeeded some twenty minutes or half an hour later by violent unilateral headache, which may persist for hours, and be succeeded by vomiting.

* Read in opening a discussion in the Section of Ophthalmology at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

What is the mechanism of the headache in this condition? There seems little doubt that in the preliminary stage of the aura there is arterial constriction, and actual narrowing of the central artery of the retina has been observed in this stage, succeeded later by throbbing and dilatation of the vessel. This fact suggests that a similar condition of constriction of the cortical vessels, especially in the occipital region, may be concerned in the production of the hemianopia, or other varieties of the scotoma: scintillans, and that the subsequent headache is due to engorgement of the vessels and cerebral compression therefrom, the vomiting itself being suggestive of raised intracranial pressure. True migraine rarely has any direct connexion with ocular conditions, such as errors of refraction, though I have known a case in which repeated attacks of apparently typical migraine occurred for about eighteen months following a corneal ulceration and the subsequent astigmatism from scarring.

True migraine so often commences in early life—and, indeed, may be traced back to the periodic vomiting attacks that occur in infancy—and these headaches in children will very likely lead to consultation with an oculist, with the frequent discovery of small errors of refraction and the prescription of glasses therefor, in the hope of curing the headaches, but the true migraine headaches differ entirely from the headaches that are commonly produced by errors of refraction. Migraine is a periodic headache, coming on at irregular intervals, which lasts usually for twelve hours or longer, sometimes for a couple of days, and is generally associated with nausea and vomiting. A typical case will be preceded by the aura of scintillating scotoma, or hemianopia, or perhaps tingling along the lips and tongue, and even a temporary aphasia and weakness of an arm, rarely the leg. These are obviously cerebral effects, and should not be confounded with the different forms of refractive headache. Often there is a family history of the same condition, and other neuroses may be present in the family.

Headaches from Refraction Errors

These are probably dealt with more fully by the ophthalmic surgeons, but they appear to be not diagnostic from their location at any particular part of the head. The pain may be over the eyebrows, frontal region, or back of the head and neck. It may be one-sided, or it may be diffuse. It is not always the more severe forms of high hypermetropia or severe astigmatism that cause the most troublesome headaches, which are sometimes due to comparatively slight errors of astigmatism. The pain is not always produced only by using the eyes, but may be present on waking in the morning, and troublesome headaches which are not periodic and paroxysmal, as in migraine, should always be treated by corrective glasses, if definite errors of refraction are found and no other obvious cause is apparent. More particularly is headache likely to be produced when these errors are different in the two eyes.

Further Ocular Causes

Another cause, which no doubt will be fully gone into by the ophthalmic surgeons, will be headache referable to want of muscular balance, heterophoria, esophoria, and the like. Yet another cause that I have seen referred to recently is the difference in apparent size of the images perceived by the two eyes, so that there is a difficulty in acquiring true stereoscopic vision. Again, diplopia from actual muscle or nerve paresis may be a source of neuralgic headaches, but this cause would be very obvious in the patient's complaint, and treatment need not detain us here.

Conditions within the eyeball itself are common causes of headache—namely, iritis, cyclitis, and glaucoma. In

iritis the pain appears first in the eyeball—a ciliary pain—and next spreads to the brow and temple along the supraorbital nerve; it may be very severe, throbbing and stabbing, and increasing at night. Sometimes the pain may be referred along the side of the nose, the infraorbital area, even into the cheek.

The pain in acute glaucoma may be very distressing, though its cause is not likely to be overlooked, but in chronic glaucoma neuralgic pains about the face and head are commoner perhaps than is generally believed. For example, in Parsons's textbook, *Diseases of the Eye* (seventh edition, 1934), in his description of chronic glaucoma, no reference is made to pain, and I have heard an ophthalmic surgeon assert that pain is never a symptom of chronic glaucoma. On the other hand, De Schweinitz writes, in his textbook (tenth edition, 1934, p. 417), after describing the pain of acute glaucoma:

"In chronic cases there may be only a general feeling of discomfort, a sense of fullness, occasional shoots of neuralgia, or attacks described by the patient as headache, or pain is entirely absent."

I have seen at least two patients in which violent neuralgic pains in the face, cheek and jaws, and temple appeared to be due mainly, or aggravated by, the presence of chronic glaucoma.

In choroidal tumour, if the tension is raised, a brow pain and neuralgia may be the symptom. The pain of corneal ulcers may be considerable, but is referred mainly to the eye itself, though the general distress and photophobia may lead in some subjects to general headache. Orbital abscess or tumours in this region naturally will be the source of pains referred to the brow and cheek, and if there is marked proptosis, and if the growth invades the eyeball, pain may be referred to the eye itself. Similarly, in exophthalmic goitre, when the proptosis is extreme, ulceration of the cornea may occur, associated with pain and headache. Frontal or ophthalmic herpes may be complicated by certain ocular conditions, such as corneal ulceration, iritis, perforation of the cornea, and panophthalmitis. The violent pains of ophthalmic herpes are, of course, well known, but occasionally—especially in old people—the persistence of the neuralgia is extremely distressing, and this may go on for years, and may apparently be permanent.

Headaches from Cerebral Disease and Neuralgia

The headaches of cerebral tumour, abscess, or meningitis need not detain us here, though papilloedema is a common physical sign in tumour or abscess. In meningitis the disks may remain normal throughout, though slight blurring of the edges is not uncommon. In sinus thrombosis headache may be very severe, and retinal haemorrhages may be most extensive.

The headache of cerebral arteriosclerosis is an important one to be recognized. After middle life it will usually be associated with increased blood pressure, and the pain is more or less continual for days or weeks, though it may clear up at times. These cases will be recognized first by the ophthalmic surgeon by the ophthalmoscopic appearances, by slight haemorrhages around the disk, and the well-known silver wire arteries, with their compression of the veins where the latter are crossed by arterial branches, and in more pronounced cases by the more definite appearances of albuminuric retinitis. The headache is often of a bursting character, and may be worse at night. There may be other symptoms of uraemia, such as vomiting and asthmatic attacks.

Neuralgic headaches that physicians meet with commonly, and which have often been treated extensively by throat and nose surgeons, and by prescribing of spectacles, are the various forms of migrainous neuralgia,

maxillary neurosis, and supraorbital neuralgia, together with the headaches which may be due to frontal and antral sinusitis. These latter are very common after catarrhal infections, or infections from the teeth, and should not be difficult to recognize by transillumination and x-ray, though they have no special connexions with the eye.

A common form of pain in the face, usually referred to the cheek, side of nose, and temple, is almost peculiar to women, and I have termed it "maxillary neurosis," or chronic neuralgia of the jaw. In many cases the pain has started after severe dental extraction, and, being unilateral, is thought to be a true neuralgia due to some piece of decayed stump or diseased bone. These cases usually run the gauntlet of nose and throat surgeons, dentists, and ophthalmic surgeons, before being seen by a neurologist. Patients often complain of a certain amount of swelling and flushing over the cheek, and though all the remaining teeth may be removed, the antrum washed out, turbinal bones removed, and glasses prescribed, the pain continues unabated. The pain is not paroxysmal or tic-like in character, but is more or less persistent, though it varies at different times of the day. No operative treatment is of any value, and alcohol injection should always be refused to these patients.

REFLEX ASTHMA: ITS PATHOLOGY AND TREATMENT

INCLUDING A REVIEW OF 337 CASES*

BY

H. H. MOLL, M.D., M.R.C.P.

ASSISTANT PHYSICIAN TO THE GENERAL INFIRMARY AT LEEDS

Bronchospasm may be produced reflexly in many different ways, but the nose is the most important source of reflex asthma. A distended stomach and a distended rectum may both produce reflex attacks of asthma quite independently of any form of alimentary toxæmia. As Hurst¹ points out, the evacuation of the stomach or of the rectum produces immediate relief long before a change could take place in the blood from diminished absorption of poisons. In certain cases the cause of irritation appears to be central and psychical, but in such cases the action is not a reflex one. The purely nervous or psychical factor will therefore not be considered in this paper.

Mechanism

Some observers hold that reflex stimulation may arise in the lung itself. A focal lesion in the lung, such as an old healed and calcified tuberculous focus, may irritate the afferent fibres of the vagus nerve and so cause reflex asthma. The reflex action from the nose occurs through the naso-pulmonary reflex. This reflex has a reflex arc composed of the trigeminal nerve and the vagus nerve. The afferent, or sensory, branch of this arc consists of the ophthalmic and superior maxillary divisions of the fifth nerve, and of the sensory root and the sensory end nucleus of the trigeminus. The efferent, or motor, branch is formed by the dorsal motor nucleus of the vagus, the nucleus ambiguus, and the efferent fibres of the vagus nerve (see Figure). Certain parts of the nose are more closely connected with the naso-pulmonary reflex than others, and the area of the nose which, if stimulated, is more likely to cause bronchospasm has been called the asthmagenic area, the trigger area, or the ethmoid region. This area begins with the lower margin of the middle turbinal, and includes all of the upper air passages extending from this margin to the cribriform plate, both the lateral and septal surfaces of the nose being included. It is bounded in

* With a grant from the Asthma Research Council.

front by the anterior end of the middle-turbinal, extends posteriorly to the sphenoid body, and may include the sphenoid cavity. Laterally it extends from the septum to the lateral plate of the ethmoid. Although clinically it is very difficult to produce asthma by stimulation of this area, it is possible in an asthmatic with a hypersensitive nose to produce another reflex action which is often significant—namely, the naso-facial reflex.

If by means of a probe one stimulates the asthmagenic area, and especially the middle turbinal, it is often possible to produce the following manifestations:

1. Intense lachrymation, at first homolateral and then bilateral, with hyperaemia of the conjunctiva.
2. A reflex flush of the ala nasi; the flush sometimes extends to the eyelids, the cheeks, the forehead, the ear, and even to the neck.
3. A swelling of the nasal mucosa giving rise to a profuse rhinorrhoea.
4. A homolateral mydriasis, a spasmodic cough, and in extreme cases nausea, palpitation, collapse, and loss of consciousness.

The presence of a naso-facial reflex is often a useful diagnostic sign, as it indicates that the asthma is probably of reflex origin.

Course of trigeminal, vagus, and glossopharyngeal in the brainstem. The diagram represents the arc through which the naso-pulmonary reflex is produced. The sensory portion of the vagus and glossopharyngeal and the motor portion of the trigeminal have been omitted. (Modified from Villiger.)

Another reflex action which may be observed in allergic subjects is obtained by intense illumination of the interior of the eyeball; this may cause a sneeze reflex, a cough reflex, or even an attack of asthma. Many hay fever sufferers find that they are worse when exposed to bright sunshine, and this is also the case with many asthmatics. Sunlight may give rise to asthma or hay fever even apart from any reflex action. Patients may be sensitive to sunlight in the same way as they may be sensitive to foreign proteins; physical allergy is now a well-recognized condition.

In addition to reflex stimulation, abnormal conditions of the nose may lead to asthma by many other ways. It is true that the most direct way of causing asthma is by reflex stimulation; spurs and deflected septa causing contact with the middle and superior turbinates may "tickle" the ethmoid region and incite bronchospasm. A septic focus (infected tonsils, infected sinuses) may, however, give rise to asthma by infecting the lungs; the patient may also become sensitized to bacterial toxins, and may react to them as to any other allergen.

A mechanical effect may also be brought about by the presence of growths or enlargements blocking the airway, so that mouth-breathing becomes necessary, and the onus of warming, moistening, and purifying the inspired air is transferred to the bronchi, which are thus constantly irritated.

Earlier Experiments

The importance of the nasal factor in asthma was first recognized by Herck in 1844. It is interesting to note that this clinical discovery followed very closely the experimental demonstration of Williams² in 1840, by means of which he was able to prove the presence of muscle fibres in the bronchi which had been described by Reisseisen some twenty years before. Williams's experiment consisted of connecting the trachea with a water manometer and noting the difference of pressure obtained by applying a galvanic current to the lungs. The experiment was made on dead animals. In 1876 Gerlach began to experiment on living curarized animals, and produced bronchospasm by stimulating the vagus nerve. He was followed by a number of other experimenters—Sandmann (1890), Einthoven (1893), François Franck (1893), Doyon (1897)—who by various methods were also able to demonstrate the presence of constricting fibres in the bronchi. The results of these early experiments were, however, in most cases both unsatisfactory and contradictory, and it was only in 1903 that a real advance was made by the researches of Dixon and Brodie.³

Without doubt the experiments made by these two observers were the most important and the most precise which hitherto had been made; even to-day they constitute the scientific foundation of our knowledge of reflex constriction of the bronchi. The success of the method adopted by Dixon and Brodie lay in the fact that they demonstrated broncho-constriction by registering changes in the volume of air passing through the bronchi, whereas previous observers had only registered changes of pressure.

Dixon and Brodie, by means of their experiments, were able to demonstrate the presence of both broncho-constrictor and broncho-dilator fibres in the vagus nerve. Later, Dixon, working with Ransom,⁴ was also able to show powerful broncho-dilator nerves of sympathetic origin; reflex broncho-constriction was demonstrated experimentally, as well, by the stimulation of the nasal mucous membrane. The best site for stimulation of the nose was the upper and posterior part of the nasal septum, which clinically corresponds to part of the asthmagenic area. Dixon and Ransom in 1913 also demonstrated broncho-constriction of reflex origin by stimulating the central cut ends of various afferent nerves, such as the central end of the vagus and the central end of the thoracic sympathetic. Prevost and Saloz,⁵ working on tortoises, obtained broncho-constriction by stimulating a number of peripheral nerves.

Pathology

From all this experimental evidence one may conclude: (1) that stimulation of the vagus nerve causes broncho-constriction, and (2) that reflex broncho-constriction can be obtained in a number of ways, although stimulation of the nasal mucous membrane proves always to be the most efficacious.

If now one transfers these experimental results to the clinical aspect of asthma, one is faced with a very difficult problem. Irritation of the nose and nasal abnormalities are of very frequent occurrence, yet in only a few cases do they cause asthma.

Thus Becker⁶ in 360 cases of nasal polypi found asthma in only nine cases, or in 2.5 per cent. of cases. Hering in 200 cases found seven cases of asthma, and Schmiegelow in 139 cases thirty-one asthmatics.

These figures show that a source of nasal irritation by itself does not necessarily cause bronchospasm unless the naso-pulmonary reflex is unduly active. What causes this state of irritability of the naso-pulmonary reflex which enables a reflex action to occur and cause asthma?

Many suggestions have been made, but none of them has as yet given a final solution to this fundamental problem of asthma.

Stoland, Sherwood, and Woodbury⁷ have shown that the excitability of the vagus nerve (chronaxie) is increased by the previous injection of foreign sera. An analogous state has been described by Freund and Gottlieb,⁸ who found that peptone or foreign serum causes an enormous increase in the

Aug. 18, 1934]

salivary response to pilocarpine. In this connexion it is interesting to note an experiment made by Dodel. Dodel⁹ found that the action of pilocarpine in guinea-pigs is enhanced by producing a chemical bronchitis by means of a few whiffs of chlorine gas. A dose of pilocarpine, which in the ordinary way would not be a fatal dose, kills the animal in thirty minutes after the bronchitis has been produced. He concluded that the bronchitis produced by the inhalation of chlorine had concentrated the vagotropic action of pilocarpine on to the respiratory system. In a similar way, a chronic respiratory infection in man may cause increased vagal action and thus lead to asthma.

It has been a moot point whether asthma is associated with a state of acidosis or alkalosis, but now there is good evidence to show that an asthmatic attack may be accompanied or may be induced by a state of alkalosis. Epstein¹⁰ states that in asthma there is a tendency to alkalosis similar to that found in other states, such as spasmophilia, certain cases of eczema, in anxiety neurosis, and in melancholia. Certain conditions tending towards acidosis are, on the other hand, often incompatible with asthma, such as acidosis of the last months of pregnancy, of prolonged vomiting, and of diabetes mellitus. He mentions that in 2,500 cases of diabetes mellitus asthma was recorded in only two cases. Tiefensee¹¹ found that the alkaline reserve during free intervals was normal, but that it was raised during an attack of asthma.

There may be a diurnal, seasonal, and sexual variation in vagus activity. McDowall¹² points out that when an individual is at rest vagus activity is at its maximum. Asthmatic attacks are certainly more liable to occur at night, during the week-end, or after a meal. The ionic environment of the bronchi may have a definite influence on bronchial spasm. Pottenger¹³ points out that calcium acts in harmony with sympathetic stimulation, and potassium—and to a less extent sodium—in harmony with vagus stimulation. Increased parasympathetic action presupposes a relative increase in potassium as compared with calcium ions in the cells, either an actual decrease in the calcium or an actual increase in the potassium. Pottenger found that the K/Ca ratio in the blood of normal persons is about 2, but that in asthmatics the ratio was always high (2.04 to 2.93, averaging 2.48). In only one case did it fall below 2.19.

Direct proof of calcium deficiency in asthma is lacking, and a large series of cases at the New York Hospital studied by Lemke¹⁴ shows no significant calcium deviations from the normal.

Review of Clinical Case

During the last four years 337 cases of asthma, which have been seen at the Asthma Clinic of the General Infirmary at Leeds, have had an anterior rhinological examination. In practically every case the rhinological examination has included a transillumination test, and in many cases also an x-ray examination. An examination of the nose and throat has been carried out irrespective of the type of asthma, and of whether or not nasal symptoms were present. In every case the patient has been referred to the ear, nose, and throat department of the hospital for the examination of the nose and throat. The largest proportion of cases was composed of adults, and only 15 per cent. (fifty-two cases) were children under 10 years of age. Of the adult cases 60 per cent. belonged to the first four decades and 25 per cent. were over 40 years of age.

For the purpose of this study it will be convenient to discuss the relation of the nose and throat to asthma under three headings—namely, nasal symptoms, type and frequency of nasal abnormalities, and value of nasal operations.

Nasal Symptoms

About half the patients complained at one time or another of vasomotor symptoms of the nose or throat

(see Table I). The most common symptom was sneezing (25 per cent. of cases). The sneeze was rarely single, but generally occurred in prolonged, violent, and paroxysmal seizures of ten, twenty, or more stertutations in rapid succession. Unlike hay fever or paroxysmal rhinitis, sneezing often occurred alone, and was not accompanied by rhinorrhoea or itching of the eyes. The attacks were more severe at certain hours of the day—for example, at night, or on first rising in the morning—but they also occurred throughout the day. In some cases sneezing

TABLE I.—General Symptomatology
(323 Cases of Asthma)

Symptoms	Number of Cases	Percentage
Sneezing	63	25.0
Rhinorrhoea only	19	6.0
Sneezing and rhinorrhoea	17	5.0
History of "colds"	41	12.0
Dryness or fullness of the nose	2	0.6
Seasonal hay fever	11	3.4
Sore throat	2	0.6
Hoarseness, aphonia	2	0.6
Ears, deafness (seasonal)	2	0.6
Total number of cases with vasomotor affections of the nose and throat	164	50.3

occurred independently of the attacks of asthma, while in other cases it represented the prodromus of an asthmatic attack. Occasionally, on looking back into the history of an asthmatic, one found that persistent sneezing had taken place many years before the asthma had actually started, and had been the first indication that the patient was an allergic subject. Another common vasomotor symptom was rhinorrhoea (11 per cent. of cases). In about half the cases it occurred alone, while in the other half it accompanied sneezing. Itching of the eyes, lachrymation, and photophobia were exceptional symptoms, unless the patient was also a sufferer from seasonal hay fever.

Patients frequently stated that the asthma first started from a "neglected cold," or that the attacks of asthma were heralded in by a cold, which afterwards "settled on the chest and caused the attacks of asthma." This type of history was obtained in 12 per cent. of cases. In the great majority of cases, however, what was described as a cold was not a true coryzal attack, but a vasomotor reaction of the nose representing the first stage of a general allergic reaction, which later manifested itself in an asthmatic attack. This is an important point, as many cases of asthma are erroneously attributed to an infective factor in view of a history of repeated "colds," and are treated by stock or autogenous vaccines, with little benefit, when the real cause is hypersensitiveness to an allergen, and the removal of, or the desensitization to, this allergen often dispels both the "colds" and the asthma.

The distinction between the vasomotor reactions of the nose in asthma and the common cold should not be difficult; in pure vasomotor rhinitis the secretions are always serous, whereas in the case of a true coryza the secretions are in a certain stage muco-purulent. Occasionally the pharynx may also become involved in an attack of asthma. The most common symptom is a dry, irritating, and hacking cough due to itching of the palate and of the upper portion of the trachea. More rarely, the pharynx and the uvula may become greatly inflamed and oedematous, and the patient may complain of marked soreness of the throat. The condition may also extend to the larynx, giving rise to hoarseness and to aphonia. Periodic and

sometimes seasonal deafness may also occur, due to the Eustachian tubes being involved.

All these vasomotor reactions of the nose and throat may precede, accompany, or follow an attack of asthma. The patient may remain free from asthma as long as the vasomotor nasal symptoms persist (especially the rhinorrhoea), but as soon as they cease the patient develops an attack.

Vasomotor affections of the nose were more frequently found in asthmatics during the first five decades of life. After 50 there was a distinct decline in the frequency, and only 7 per cent. of cases complained of nasal symptoms after this age. Vasomotor affections of the nose and throat occurred in all types of sensitivity and in sensitivity both to foods and to inhalants, but were definitely more common in pollen-sensitive cases when one included seasonal hay fever as well. In the other cases they occurred as frequently in subjects exhibiting positive skin reactions to one or more allergens as in those with negative skin tests, and indeed the latter showed a slightly higher frequency (see Table II). This may be explained by the

TABLE II.—Skin Reaction
(198 Cases of Asthma)

Skin Reaction	(a) Cases with Vasomotor Affections of the Nose or Throat	(b) Cases with Seasonal Hay Fever	Total with (a) or (b)	
			No.	Per cent.
Positive skin test to pollen (48 cases)	20	10	30	62.0
Total number of sensitive cases (124 cases)	48	10	58	47.0
Ca es wi h negative skin tests (74 cases)	37	1	38	51.0

fact that cutaneous and mucous membrane sensitivity do not always run parallel; thus, in the perennial form of paroxysmal rhinitis unaccompanied by asthma it is a common finding that skin tests are negative, even when there is a definite history of sensitivity to some allergen.

Nasal Abnormalities

In the present series of cases no fewer than 262 cases (77.9 per cent.) showed some abnormality of the nose and/or throat. In many cases, however, these abnormalities were casual findings or minor causal factors (see Table III).

TABLE III.—Nasopharyngeal Condition
(337 Cases of Asthma)

Type of Abnormality	No. of Cases	Percentage
Spur	15	30.9
Deflected septum	80	
Hypertrophy, inferior turbinals	48	24.0
Hypertrophy, middle turbinals	34	
"Tonsils and adenoids"	78	23.0
Antra dark:		
Explored positive (infected) ..	21	21.0
Explored negative	30	
Not explored	22	
Polypi	18	6.7
Recurrent polypi	5	
Rhinitis sicca	3	0.9
Chronic rhinitis	4	1.0
Nasal hyperaesthesia	3	0.9
Lingual tonsil	1	0.3
Pharyngeal tonsil	1	0.3
Nasopharynx normal	75	22.1

N.B.—Cases showing two or more abnormalities have been included more than once in this table. The number of cases appearing in the table exceeds, therefore, the number of patients examined.

Deflected septa or spurs were found in 105 cases (30.9 per cent.), but in a large number of cases the deformity was slight and of no significance. Inferior and middle turbinal hypertrophy was also a frequent finding, and was noted in eighty-two cases (24 per cent.). A third large group of cases showed tonsillar and adenoidal hypertrophy or infection, and this was observed in seventy-eight cases (23 per cent.). Lastly, opacity of one or more sinuses either to the transillumination test or to x rays was found to occur also with great frequency, and was present in seventy-three cases (21 per cent.). The antra were explored in fifty-one cases, and were found to be definitely infected in only twenty-one instances. In the remaining thirty cases the opacity was probably due to hyperplastic changes of the mucous membrane lining the antra, as exploration proved negative and no pus was found.

A striking example of such a condition was given by a patient who was specifically sensitive to rabbit hair. The antra were first examined while the patient was still exposed to the offending allergen and was continually having severe and frequent attacks of asthma. The antra were found to be completely opaque, both on transillumination and to x rays. One antrum was explored, but with negative result. The patient was then advised to avoid contact with rabbits (the husband was a keen rabbit breeder), whereupon she immediately ceased to have asthma, and the antra, examined a month later, were found to be perfectly normal and translucent again.

Polypi were not a frequent finding, and were observed in only twenty-three cases (6.7 per cent.). In five of these cases they had a tendency to recur, in spite of the numerous operations which the patients had undergone for their removal.

Rhinitis sicca, chronic rhinitis, and lingual or pharyngeal tonsils were only occasional findings. Definite nasal hyperaesthesia was also distinctly uncommon, and was observed in only three cases. An analysis of the incidence of nasal abnormalities among different groups of cases classified according to whether they gave a positive or a negative skin reaction showed that deflected septa and nasal spurs occurred with a remarkably constant frequency in all groups (see Table IV). This was to be expected,

TABLE IV.—Skin Reaction and Nasopharyngeal Condition
(213 Cases of Asthma)

Skin Reaction	Naso-pharynx Normal	Spur or Deflected Septum	Tonsils and Adenoids	H.R.*	Polypi	M.T.B.† Enlarged	Sinusitis
	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
Positive to pollen only (30 cases)	30	30	33	6.6	0	15	0
Protein-sensitive cases (128 cases)	25	30	22	14	7.9	10.9	0
Cases with negative skin tests (55 cases)	26.1	30	17.4	11.7	7.0	9.3	7.0

* Hypertrophic rhinitis. † Middle turbinate bone.

as these nasal abnormalities are not dependent upon any allergic cause, and are quite coincidental as far as allergy is concerned. With regard to conditions which might be the result of hyperplastic changes of the nasal mucous membrane (turbinal hypertrophy and opaque antra), they were found a little more frequently in protein-sensitive cases.

The cases with negative skin reactions gave instead the highest incidence of definite sinus infection. Cases exhibiting a positive skin reaction to pollen had the highest percentage of normals, and of thirty such cases reviewed not a single case presented polyposis or sinus infection. Kern and Donnelly,¹⁵ in discussing the incidence of paranasal sinus disease in hay fever, found that patients with uncomplicated hay fever and patients with hay fever and seasonal asthma showed an incidence

of sinus abnormality that was less than in the average (normal) population. Although pollen-sensitive cases of asthma present nasal symptoms with the greatest frequency, they have the lowest incidence of nasal abnormalities, and it is quite common to find that hay fever subjects and patients with seasonal asthma have perfectly normal noses.

Operative Results

Of the 262 cases showing some type of abnormality of the nose and/or throat, 135 cases have received operative treatment, and of these the results are known in 109 cases. These include thirty-one children.

The period of observation after the operation has varied from a minimal period of six months up to fifteen years, and the average period has been two and a half years. In 19 per cent. of cases the period of observation was under a year, in 25 per cent. of cases one or two years, and in 56 per cent. of cases over two years. All the patients were seen at the asthma clinic, or if they had ceased attending the clinic were circularized and asked to reply to a questionnaire.

Patients were deemed "cured" if they had kept completely free from asthma for a period of at least two years, and "improved" when the attacks of asthma had definitely lessened in severity and/or frequency. The latter do not include patients in whom the operation had improved the breathing but had left the asthma unchanged. In many cases it was impossible to say definitely whether the improvement was due solely to the nasal treatment, as the patients had received other forms of therapy as well, and in such cases one could only infer that the improvement had taken place with nasal treatment rather than by it.

The operative results show that forty-one cases (or 37.5 per cent.) improved after nasal treatment, and three cases (or 2.7 per cent.) were "cured" (see Table V). Another fourteen cases showed some temporary improvement, thus bringing the number of cases which somewhat benefited from surgical treatment of the nose and throat

up to 55 (or 50.4 per cent.). Of the cases which were improved only twenty-one have been kept under observation for a period of over two years, and can be regarded to have definitely benefited from the operation, while the remainder are still an uncertainty. Thus one may state that of 109 cases which received surgical treatment only about one out of five has been definitely successful.

Of the three "cures" one followed a tonsillectomy, another tonsillectomy and submucous resection, and a third occurred after the removal of a polyp. In all three cases there was some definite indication for operative treatment, and the "cure" could be attributed directly to the operation.

Among the failures, in two cases the asthma was made worse after the operation, and in five cases the asthma actually made its first appearance after the operation. In all these cases the operation had been either a tonsillectomy or a submucous resection of the septum, two operations which may be dangerous in asthma.

Tonsillectomy may prove harmful to an asthmatic when the tonsils are not definitely infected but are merely hypertrophied, as the tonsillar hyperplasia may be a protective mechanism in resisting infection. It is to be noted that pollen-sensitive cases and cases sensitive to inhalants have a higher percentage of "tonsils and adenoids" than any other group (see Table IV). A submucous resection of the septum may aggravate or even induce asthma by creating an irritable ethmoid area, because the mucous membrane covering this area may, in the course of the operation, have become contused and damaged, and the sensory nerve endings may have become unduly irritable.

Discussion of Treatment

The figures given above are somewhat disturbing, and unfortunately no more encouraging results can be obtained from a survey of the literature of the past twenty years. Although the results given by different observers vary considerably, and the percentage of improved cases ranges between 43 and 85, and that of "cured" cases between 1.6 and 48, on taking an average figures not very different from our own are obtained. Thus of a total series of over 700 operated cases reported in the literature, an average of 56 per cent. of cases have improved, and about 10 per cent. have been "cured" (see Table VI).

TABLE VI—Results with Other Observers

Author	Year	No. Cases Operated	Improved	Cure
			No. Per cent.	No. Per cent.
Dundas-Grant ¹³	1913	53	32 60.3	11 20.8
Heatley and Crowe ¹²	1925	62	53 85.4	1 1.6
Tod ¹⁰	1925	173	75 43.0	12 12.0
Lierle ¹¹	1926	21	17 80.0	2 10.0
Leopold and Fetterolf ¹⁴	1927	21	12 50.0	5 43.0
Rackemann and Tobey ¹⁵	1923	258	129 50.0	15 5.0
Lyon and Murray-Lyon ¹⁶	1930	115	77 66.9	10 13.3
Averages	—	706	56.0	10.0

Some authors take a very pessimistic view on the value of nasal treatment in asthma, and Piness and Miller¹⁸ state that in a group of 834 allergic patients 704 operative procedures on the nose and throat were done on 413 patients without relief, there having been no removal of the offending allergen. Kahn¹⁷ has also reported a group of ninety-four consecutive cases of asthma in which thirty-three received operative treatment. In fifteen cases relief of the nasal obstruction was obtained, but the asthma was unchanged.

TABLE V.—Operative Results
(109 Cases)

Operation	Total No.	Cured	Much Improved	Improved	Temporarily Improved	Unchanged	Worse	Asthma first appeared after Operation
Tonsillectomy	43	1	5	5	4	24	1	3
Tonsillectomy and middle turbinectomy	2	0	2	0	0	0	0	0
Tonsillectomy and inferior turbinectomy	1	0	1	0	0	0	0	0
Tonsillectomy and submucous resection	6	1	1	2	0	2	0	0
Submucous resection	11	0	1	2	1	5	0	2

Pharyngeal tonsil removed	1	0	1	0	0	0	0	0
Total	109	3	23	13	14	44	2	5

While indiscriminate operations on the nose and accessory sinuses of asthmatics should be condemned, they must, if attempted, be radical. Thus it is useless to remove a polyp without treating the underlying sinusitis, as the polyp will recur. Similarly, it is essential in the case of an enlarged middle turbinal, which is pressing on the posterior septum, to remove that portion of the turbinal which touches and irritates the sensitive part of the septum. Definitely infected sinuses should always be treated either surgically or more conservatively by means of intranasal irrigation, nasal packs (Dowling pack), inhalations, and sprays. The hyperplastic type of sinus disease should, however, never receive operative treatment, and should be left severely alone. The same may be said of swollen and oedematous turbinates which are not causing nose-block and are not impinging on the sensitive area. Polypi should be removed, but the operative results are distinctly poor on the whole, except for an occasional brilliant success. In some cases they have a great tendency to recur, and the patient undergoes numerous operations with very little benefit unless the accompanying sinusitis is treated as well. Tonsillectomy should be done whenever the tonsils are definitely infected, but not otherwise; in a certain number of children the results are gratifying.

As a corollary to nasal treatment it is most important that the patient should be educated to breathe correctly once a free air-way has been established. Many patients, who habitually or from some nasal block are mouth-breathers, have to be re-educated to breathe through the nose. Often these mouth-breathers rapidly develop a typical asthmatic chest, over-expanded in its upper half, narrow at the base, and taking the shape of an inverted flask. This deformity is due to the fact that during an asthmatic paroxysm the respiration in these patients is almost entirely of the upper thoracic type, the lower part of the chest remaining practically immobile owing to a spasm of the diaphragm. Expiratory breathing exercises and exercises devised to develop diaphragmatic breathing are of the very greatest value in such cases.

In concluding, one may say that nasal symptoms often do not disclose the part which the nose is playing as an aetiological factor in asthma, as they themselves may be due to an allergic reaction. The presence of nasal abnormalities in the nose and throat is of no greater help, as they are often coincidental or are also a result of the asthma.

1. In a series of 326 cases of asthma about half the number of patients complained at one time or another of nasal symptoms. These symptoms were mostly due to vasomotor affections of the nose and not true coryzal attacks.

2. Vasomotor affections of the nose and throat occurred in all types of sensitivity, but were definitely more common in pollen-sensitive cases of asthma.

3. Abnormalities of the nose and throat were found in 77.9 per cent. of cases, but were mostly coincidental and minor causal factors.

4. Turbinal hypertrophy and hyperplastic sinus disease were often the result rather than the cause of the asthma, and were found slightly more frequently in protein-sensitive cases.

5. Of 135 cases which received operative treatment, 109 cases were followed up, and of these 50.4 per cent. were improved and 2.7 per cent. (three cases) were "cured."

I am indebted to Mr. E. W. Bain and to Mr. W. Maxwell Munby for the rhinological reports of all the cases reviewed in this paper.

THE TREATMENT OF BACTERIAL FOOD POISONING

BY

GEORGE R. McROBERT, M.D. ABERD., M.R.C.P. LOND.,
D.T.M. and H.

MAJOR I.M.S., BURNIA

Although bacterial food poisoning is by no means uncommon in Great Britain, it is in the more torrid portions of the world that it takes a really prominent place among the acute medical emergencies met with in practice. The low standard of personal and family hygiene among those who handle and cook food in many warm countries, together with the prevalence of flies and conditions of atmospheric temperature and humidity most suitable for the multiplication of the organisms concerned, lead to the high incidence of the *Salmonella* type of bacterial food poisoning.

Symptomatology

Many persons spend years of residence in warm countries without contracting malaria, dysentery, or other characteristically tropical diseases, but few escape one or more attacks of the condition now under consideration.

The following is a typical case from my records:

Of eight persons dining together in Rangoon one night in 1928 five partook of the savoury, at 9 p.m. All five suffered from bacterial food poisoning—the symptoms showing themselves in Mrs. A. at 3 a.m., Mrs. B. at 8 a.m., Mr. A. at 10 a.m., Mr. B. at 11 a.m., and Mr. C. at 4.30 p.m. The severity of the attacks and the rapidity of onset were definitely correlated—Mrs. A. having severe vomiting and diarrhoea and marked collapse, whilst Mr. C. had moderate abdominal pain and diarrhoea, without vomiting and collapse.

It is not only essential, therefore, that medical men practising in such countries should have a firm grasp of the principles of treatment, but it is important that those acting in an advisory capacity to services and firms with men working far from medical help in jungles and forests should issue "first-aid" instructions for the future benefit and protection of their clients.

In severe infections the incubation period is short (two to six hours), and although all those who eat the infected food may suffer acutely, one patient may be very much worse than the others. In such cases it is not unusual to find that the patient most severely afflicted has been suffering from a mild gastro-intestinal upset for some time.

Captain M., aged 25, staying at a hotel in India in 1920, had been suffering from loss of appetite, furred tongue, and mild diarrhoea for over a month without reporting sick. He

Aug. 18, 1934]

was awakened early one morning by violent abdominal pain. Severe diarrhoea occurred, and the motions, at first coloured, soon became "rice-water" in appearance and consistency. Violent vomiting ensued after the purgation had commenced, and a state of collapse was soon reached. The tissues were greatly dehydrated, the condition of "washerwoman's fingers" was noted, and, before losing consciousness, the patient complained of agonizing leg cramps. He ultimately recovered, but was confined to bed for three weeks. A number of other guests at the same hotel suffered from abdominal pain and moderately severe diarrhoea without collapse, but in Captain M. alone were the symptoms suggestive of cholera, which diagnosis was excluded by bacteriological examination, an organism of the *Salmonella* group being held responsible.

The notion that diarrhoea and vomiting may be treated by opiates only dies hard, and much harm has been done in the past by too early and too frequent recourse to the camphorodyne or laudanum bottles, with resulting intestinal stasis, multiplication of pathogenic organisms and their toxins, and rapidly developing toxæmia.

Principles of Treatment

The rules to be adopted in dealing with cases of bacterial food poisoning are:

1. Rest in bed.
2. No solid food.
3. Neutralize the effects of toxins already absorbed.
4. Prevent further absorption.
5. Allay the pain.
6. Ensure the removal of the infecting organisms and their poisonous products from the body.
7. Gradually work up the diet from liquid only, through stages of bland, non-irritating substances, to normal.

All but the very mildest cases should be dealt with as bed patients. Warmth is essential—general, as well as local to the abdomen, in the form of hot-water bottles or turpentine stupes. Nothing but fluids may be given by mouth until the diarrhoea has ceased.

The administration of an ounce of castor oil with a few minims of tincture of opium or camphorodyne has formed the basis of treatment for many years, and may still be employed in mild cases. It gets rid of the irritating and infective intestinal contents, and is followed by a number of doses of an astringent mixture. It very frequently happens, however, that the stomach will not retain castor oil or magnesium sulphate, and, in the presence of severe vomiting and collapse, it has been recommended that collapse and dehydration should be combated by intravenous salines, warmth, and opium, before any attempt is made to clear out the gut by means of purgatives. Delay is nevertheless dangerous, for whilst the existing toxæmia is being dealt with the gastro-intestinal condition is getting worse, and further toxins are being absorbed.

Use of Kaolin

For some years I have completely abandoned the early use of purgatives in bacterial food poisoning, and now rely completely on the adsorptive action of fine kaolin. Kaolin B.P. is rather a gritty preparation, does not make a very fine suspension in water, and is somewhat nauseating, but there are on the market a number of fine, smooth, "colloidal" preparations of kaolin which make a palatable and even suspension in water. These are not readily rejected even by the most inflamed and irritated stomach, and they serve to detoxicate the bowel contents whilst soothing and protecting the lining of the gut. In even the most severe cases, therefore, the work of detoxicating the gastro-intestinal contents may proceed *pari passu* with the treatment of the already established toxæmia.

If collapse and dehydration are marked the patient, in bed with warm bottles and blankets, is given gum-saline or Rogers's hypertonic saline intravenously at a very

slow rate. If the patient has previously been in a poor state of nutrition glucose may be added to the saline with advantage, so as to protect the hepatic cells from the action of toxins. At the same time the oral administration of fine kaolin—2 drachms to a wineglassful of water—is commenced, sips being given as frequently as possible. Morphine 1/6 grain to 1/4 grain may now be given subcutaneously without fear of increasing the toxæmia. The amount of fine kaolin which can be retained varies in different cases, but it is generally possible to give 4 drachms of the powder in the first hour of administration; thereafter 1 drachm is given every fifteen minutes, in as much water as the patient will take, until the diarrhoea is controlled. Gastric and colonic lavage, which were formerly practised in cases of vomiting as a preliminary to the administration of castor oil, are, I believe, no longer necessary.

In cases of less severity, without collapse, rest, frequent doses of fine kaolin, and large quantities of fluid by mouth, with morphine if colic is severe, result in very rapid improvement. With the introduction of fine kaolin treatment, the use of lead and opium, kino and catechu, and other astringent mixtures formerly used as a follow-up to castor oil administration, can be abandoned. A certain amount of judgement is necessary to avoid the production of constipation by the kaolin, but the judicious use of liquid paraffin or of a saline preparation along with the kaolin, on or after the second day, obviates this minor disadvantage of the treatment.

Great care must be taken in building up the diet after the diarrhoea and vomiting have been controlled. There is still too great a tendency to make excessively free use of milk in the early stages. Milk is a solid, not a liquid, food. Chief reliance for the supply of calories should be placed on the use of glucose water flavoured with lemon juice until the acute stage is over.

Thereafter, whey, egg albumen, and Benger's food may be added, and a normal diet be gradually built up with the proviso that flesh and fibrous foods should be withheld until convalescence is thoroughly established.

Conclusion

A large number of missionaries, forest officers, and jungle employees of timber and mining firms now carry a tin of fine kaolin as part of their regular camp equipment, and reports received from them confirm my opinion that the introduction of fine kaolin is one of the most important advances in practical everyday therapeutics of recent years.

In one case an outbreak of acute diarrhoea and vomiting occurred at a missionary conference in Burma in 1932 within three hours of the evening meal. A number of elderly men and women were affected, and with such an early and acute onset one would, in the pre-kaolin days, have expected severe collapse and a good deal of anxiety in the course of treatment. Fine kaolin treatment was instituted by a missionary before I was summoned, and on my arrival nothing more was necessary than the administration of morphine to two patients and an order to continue the treatment already instituted. All the affected persons were able to leave the station within a few days.

Mr. Arthur Evans of the Westminster Hospital has very kindly presented to the medical superintendent (Sir Thomas Carey Evans) of the Hammersmith Hospital his collection of pathological specimens illustrating diseases of the gall-bladder for the museum of the post-graduate medical school, which is at present under construction. Each specimen is beautifully mounted with a complete clinical history of the case. This will be most useful for teaching purposes, and will form the nucleus for the new museum. It is to be hoped that similar collections will be added to the museum in due course.

Clinical Memoranda

AN UNCOMMON MALFORMATION OF THE HEART

A female child, born in the Maternity Hospital, Sheffield, on August 20th, 1933, was cyanosed from birth, but no adventitious heart sounds were heard until September 18th, when a rather faint systolic bruit appeared over the whole of the front of the left chest. With lapse of time the cyanosis became much less, but on September 7th there was a sudden attack of cyanosis, pallor, and apnoea lasting an hour or so. From this time up to her death at the age of eight weeks there were several similar attacks. Some signs of consolidation at the base of the left lung were found on September 20th, and gradually increased. She died of bronchopneumonia on October 19th. During the eight weeks of life the weight increased by about one pound. A blood count on September 8th showed nearly five million red cells and 100 per cent. haemoglobin.

The thoracic contents were received by me after they had been dissected at the post-mortem examination. The heart shows a transposition of the aorta and the pulmonary artery. The pulmonary artery arises from a normal-looking left ventricle, whilst the aorta arises in front of it from the infundibulum of the right ventricle, which is hypertrophied so that it is of the same thickness as the left. The aorta is normal; from its arch spring the three great vessels, and there is only a doubtful coarctation immediately beyond the origin of the left subclavian artery. There are three cusps to the aortic valve—an anterior and a right and left posterior. The coronaries arise in relation to the last two cusps instead of the anterior and left posterior as in the normal. The pulmonary artery is wide and there is no stenosis, contrary to the common finding in these cases (Walsley). The ductus arteriosus was said to have been found closed at the post-mortem examination; it is now just patent, but has possibly been ruptured before receipt of the specimen. The venae cavae and the pulmonary veins open normally into the right and left auricles respectively. There is no anomalous vein as described by Harris, Gray, and Whitney. There is a small valved patent foramen ovale, and a patency in the interventricular septum that just admits a probe.

There are thus two practically closed circulations: blood leaving the right ventricle by the aorta returns to the right auricle by the venae cavae; that leaving the left ventricle by the pulmonary artery returns to the left auricle by the pulmonary veins. It is difficult to see how the child lived for eight weeks, often neither cyanosed nor distressed. Some interchange of blood obviously occurred through the foramen ovale and the patent interventricular septum, but neither of these passages was of much size: possibly also some blood was passing along the ductus arteriosus, but this must have been very small in amount. Owing to the extensive dissection before the specimen was received it has not been possible to inject the vessels, nor to trace the bronchial arteries and veins, which must have been of great importance.

Keith explains the occurrence of such malformations by a reversal of the normal atrophic and expansion processes in the bulbus; the pulmonary part undergoing an abnormal atrophy and the aortic part an abnormal expansion. There results thus a complete failure of rotation of the pulmo-aortic septum.

I am indebted to Dr. A. E. Naish for permission to publish these notes on his case.

Reviews

A STANDARD WORK ON NEUROLOGY

In the production of his volume *Neurology*,¹ Professor GRINKER has rendered a signal service to his specialty, for it is one of the most important comprehensive works by a single author published in recent years. Within the scope of 1,000 pages is collected an abundance of facts welded together with much skill into a well-balanced whole. The reader is perhaps most impressed by the wisdom and mature judgement displayed by the author, which reflects, in addition to great ability, a deep knowledge of all those contributory subjects which make up neurology as a whole—anatomy, physiology, clinical medicine and surgery, pathology, and psychiatry. The augmentation in knowledge which has marked the last twenty years is carefully incorporated without sacrifice of the fundamental picture of disease processes that such a book needs to impart if it is to be of its true value to clinician and student. Throughout there is the mark of wide personal experience, which, together with the literary quality of the writing, consistently maintains the reader's interest. The literature is well reviewed and the chaff mercilessly winnowed from the grain. The text is accompanied by 400 illustrations, which are well chosen and of excellent quality.

The first 230 pages are devoted to a review of the anatomy, physiology, and clinical examination of the nervous system, which, while very adequate, does not reach so high a standard as the rest of the book. The statement that the Achilles' reflex is subserved by the spinal segments S_1 and S_2 is presumably a misprint, as two pages later the usual localization of S_1 - S_2 is given. Again, we think that an erroneous impression may well be given on page 157, where the author attempts to differentiate the spinal fluid findings in disseminated sclerosis according to whether the disease is clinically active or inactive, as most will agree that such changes as occur are unpredictable. In the next 250 pages follows a description of the clinical aspects of regional disease, the subject being studied from the point of view of localization rather than pathology. The sections on the vegetative nervous system and the extrapyramidal motor system constitute a particularly valuable review of what are admittedly two of the most confused subjects of neurology.

In the remaining 500 pages the approach is pathological. The section on cerebral tumours could hardly be improved on in the allotted space. Each pathological type is first described and its typical life-history discussed. Then follows a lucid account of the symptomatology of tumours in different situations. Towards their prognosis and surgical treatment the author maintains the cautious attitude of the physician who has seen many of them, realizing fully that in the nature of the disease the prognosis in the majority of cases is hopeless and that the dictum "*primum non nocere*" should constantly be kept in mind. A well-illustrated section on cerebral radiology, ventriculography, and arteriography is included. The description of the inflammatory diseases of the nervous system, pyogenic and non-pyogenic, is conspicuously full, although the classification of the non-suppurative encephalitis does not carry conviction.

In the section on diseases associated with blood dyscrasias it is of interest at the present time to note the author's emphatic view that in combined degeneration of the cord objective changes in the nervous system do not occur as a result of liver therapy, and that most of the clinical improvement is to be attributed to recovery of the patient's general health and strength, and to repair of the peripheral nerve damage. It is odd to find among

¹ *Neurology*. By Roy R. Grinker, M.D. London: Baillière, Tindall and Cox. 1934. (Pp. xii + 974; 401 figures; 38s.)

REVIEWS

AUG. 18, 1934]

the atrophic diseases so little space given to dystrophia myotonica, which is in fact hardly accorded a position as a distinct disorder.

In a work that is worthy of so much praise and deserving of so little criticism the function of a reviewer is difficult if brief. This is a book which should be read by everyone interested in neurology.

MELLOR'S CHEMISTRY

The thirteenth volume of Mellor's *Chemistry* is now ready.² Its contents are occupied entirely with Part II of the subject of iron. So extensive is the chemistry of iron and so extensively is it treated by Dr. Mellor that it has been necessary to divide the subject. Part I was treated in vol. xii. Notices have already appeared in these columns describing the twelve preceding volumes, and little is needed to supplement what has already been said in praise of the quality of the work. As has been mentioned before, it is quantitatively the most comprehensive that has yet been published on the inorganic section of chemistry. The work is remarkable for the manner in which the newest results of research are brought into juxtaposition with the observations of Faraday and others of his day. It is most useful both for immediate consultation and for finding references to original publications. All we need say is that in this volume both the qualitative and the quantitative values of the preceding volumes are maintained. We do not doubt there are many who look forward with some eagerness to the completion of the set.

DIETETICS

Since the discovery of the vitamins a wave of interest in dietetics is passing over many countries, especially Great Britain and North America. A new career of "dietitian" has resulted, and a spate of books on dietetics as well. Great caution should be exercised in accepting all that is being published. There is a danger lest complicated diets should be invented in order to prove the necessity for dietitians. In England complexity of diets and artificial difficulties in their preparation are likely to have the reverse effect. Dietitians will not be employed in hospitals if they bring with them some of the fantastic food fads which are already threatening sound and scientific dietetics.

In the United States there is apparently a large public which requires constant variety of foods and even greater variety of cooking. There is evidence of the demands of this public in the elaborate menus presented in Dr. M. A. BRIDGES's new book or *Dietetics for the Clinician*.³ Fundamentally the views of the author are sound, but he has been compelled to study the pet recipes and dietary fads of his own as well as of other countries. From this wide survey he has culled such material as he considers physiologically sound, as well as useful and essentially practical. With the aid of Miss Gallup, his dietitian, he endeavours to exemplify the principles of dietetics in the form of proper and palatable diets for the patient. He has succeeded well in his aim. The physiological principles which govern the art of selecting and preparing food in health and disease are ably presented. When, however, it comes to leaving the region of scientific principles and venturing into the realms of art it becomes obvious at once that tastes are too different to render the menus of New York palatable for the jaded appetites

of the English. The average practitioner in this country will derive little advantage from the study of the individual diets in this book. Too many foodstuffs are recommended which are never heard of in this country, and methods of cookery which are unknown. The number of "factory" foods advocated in the menus is, to our way of thinking, economically undesirable.

When dietitians are attached to the hospitals in this country it is to be hoped that they will not persuade our hospital managers to give up plain meat, bread, milk, fresh fruit, and vegetables for the expensive "factory foods." The danger is very real. Our present small band of dietitians have for the most part had to seek their training in American hospitals, or on American lines. English medicine must study its own problems of feeding and cooking in health and disease. Dr. Bridges's book may well be taken as a pattern to copy in its broad outline, and the menus it contains should be studied as illustrations of the manner in which different nations take their victuals and drink.

CHOLERA IN CHINA

Outbreaks of cholera still persist in countries such as Siam, India, China, the Philippines, and Indo-China, where a large proportion of the population still make free use of impure water. In Europe we have probably seen the last of it. A recent manual,⁴ compiled for the medical profession in China does not bring any new light to the subject. It will, however, be useful for the purpose for which it is designed, and as it is also published in Chinese it will reach a wider public, including the old-style practitioners, who are beginning to take an interest in the modern aspects and management of prevalent disease.

Cholera in China has shown an irregular periodicity, and epidemics have arisen subsequent to its appearance in India, but it is quite impossible to say if cholera in China is still solely due to importation or whether the disease has now become fairly endemic. A general view of the whole question points to the central basin of the Yangtze Valley as being the most suspicious focus of endemicity, and while investigations in Shanghai have shown absolutely negative results, even so far as the presence of non-agglutinable vibrios was concerned, yet this city, with its great inflow and outflow of people, must be regarded as the chief cholera-distributing centre of China. This volume is intended to be the first of a collection of practical manuals on the common epidemic diseases occurring in China. It marks a step in public health progress which mainly depends on the awakening of sanitary consciousness among the masses. There is yet much to do. While in most big Chinese towns there are many vastly improved public health measures, we find people drinking boiled water or tea exclusively, and yet using the most polluted water for washing fruits, vegetables, and utensils. Dr. R. Pollitzer deals with the cultural and biochemical properties of the vibrio, its serological reactions and toxins, and the bearing of laboratory findings upon the epidemiology of cholera. He adequately sums up the diametrically opposite views of various writers, especially with regard to the spread of cholera infection and the loss of agglutinativity of cholera vibrios. Perhaps the most important part of the volume is that by Dr. C. Y. Wu on education and propaganda. Dr. Wu sets himself to the task of scientifically guiding the national consciousness towards modern and proved ideas of clean living and disease prevention. He recounts the

² *A Comprehensive Treatise on Inorganic and Theoretical Chemistry* Vol. XIII, Fe (Part II). By J. W. Mellor, D.Sc., F.R.S. London: Longmans, Green and Co. 1934. (Pp. 948; 381 figures. 63s. net.)
³ *Dietetics for the Clinician*. By M. A. Bridges, B.S., M.D., F.A.C.P. In collaboration with R. L. Gallup. London: H. Kimpton. 1933. (Pp. xvi + 666. 32s. net.)

⁴ *Cholera: A Manual for the Medical Profession in China*. By Drs. Wu Lien-Teh, J. W. H. Chun, R. Pollitzer, and C. Y. Wu. Shanghai: National Quarantine Service; London: H. K. Lewis and Co. Ltd. 1934. (Pp. 197; 24 figures, 1 coloured plate. 5 dollars in China; 3 dollars in U.S.A.; 12s. in England, post free.)

experiences gained by public health bodies in Shanghai, and lays down the principles on which the next national anti-cholera campaign should be based. Dr. J. W. H. Chun discusses the clinical aspects of cholera in the light of all the modern findings and methods of treatment. He fully concurs with the dictum that almost anybody can be saved from cholera, which is merely a matter of nursing and careful attention to details of treatment. Where the cholera toxins abstract abundance of fluid by purging and vomiting there is no better or more logical means than the intravenous injection of hypertonic saline or normal saline solution. There is still plenty of occasion in the Orient for keeping in touch with the subject of cholera, as may be gathered from the data of the 1932 epidemic. There were 306 infected cities throughout China, with 100,666 cases and 31,974 deaths—a death rate of 31.8. The book is printed and published in Shanghai, and is well produced.

NORMAL SERUM

*Le Sérum Normal*⁵ is an encyclopaedia, and the bibliography, which numbers over 1,300 references, is witness that MM. Brocq-Rousseu and Roussel have spared no labour to collect all that is worth knowing about the normal serum. Owing to the frequent confusion between "plasma" and "serum" the authors have introduced the subject by a careful definition of what they mean by serum as a "liquide exsudé naturellement après coagulation du sang," and they qualify this by "un sérum normal est un sérum provenant d'un animal en bon équilibre physiologique, non soumis à des injections immunisantes."

The detailed account of the methods commonly employed in collecting serum from different species of animals—for example, horse, ox, pig, monkey, birds, and many others, including several invertebrate groups such as the crustacea—is interesting and useful. With this account are given the amounts of serum obtainable from these bleedings, the coagulation times of the bloods, and the contraction periods of the clots. It is rather curious to find the tortoise grouped with lobsters, and unfortunate that the method of bleeding a tortoise is omitted, as these animals are very difficult to bleed. After collection of the serum reference is made to "tyndalisation" and to "aging," and the methods of preserving are considered at length, desiccation being regarded as the best.

The principal sections of the book discuss the physical characters of the serum, its density, osmotic pressure, surface tension, viscosity, electrical conductivity, etc., including the various methods that have been devised for estimating their values. It is not possible in a short review to analyse the great mass of data compressed into these chapters; the information will certainly be of much use to research workers in physiological laboratories and in serum therapy institutions. To check the accuracy of the references would be a time-consuming task. In the bibliography we have noted several errors in spelling, which will no doubt be corrected by the printer in subsequent editions.

MANIPULATIVE TREATMENT

The subject of manipulative treatment is one which tends to excite among the laity an expectation of a miraculous cure by the sudden and dramatic putting back of a bone which has been out of place; among medical men it either arouses scepticism or awakens an interest which, owing to lack of literature and practical demonstrations, is difficult to satisfy. Dr. MARLIN's little book

*Manipulative Treatment for the Medical Practitioner*⁶ was written in response to many requests by interested colleagues, and presents an account of movements and manipulations all of which have been tested thoroughly and have had beneficial results. These procedures are clearly described, and photographs illustrating them show the most suitable grips for controlling movements, and the most advantageous positions for patient and operator, so that the reader will not have much difficulty in attempting similar manipulations. Where difficulty does lie, and where experience and skill count for so much, is in finding the right amount of force necessary to produce a certain adjustment and the precise moment at which to administer it. It is very doubtful whether a beginner in manipulative work would be able to produce enough muscular relaxation to allow of successful joint manipulation; for instance, attempts to stretch the tendo Achillis might result in stimulating stronger contraction.

The book contains chapters on joint manipulations in general descriptions of cases which have been treated successfully, directions for manipulation of soft tissues, and the technique of manipulating individual joints. Among the latter are described three methods of manipulating the sacro-iliac joint, four methods of treating a displaced internal semilunar cartilage, besides descriptions of procedures for treatment of tennis elbow, painful feet, and stiffness of the spine. The author disclaims any attempt to do something "magical," and considers manipulation in the light of applied physics, taking into account the shape of the articular surfaces and the leverages employed in their adjustment. Only in such a way can the fullest benefit be obtained. The book can be recommended for its open-minded approach to a difficult subject, and the practitioner who reads it will look forward with eagerness to trying some of these manipulations on the next foot-weary, stiff-backed patient who comes his way.

Notes on Books

The appearance of a fifth edition of *Diseases of Women*, by TEN TEACHERS,⁷ indicates that this well-known textbook is maintaining its deserved popularity. The principal changes in the new edition are in the section dealing with the sex hormones of the ovary and pituitary. The present knowledge of these subjects has been very fully and clearly summarized, and the need to avoid unwarranted expectations in regard to the therapeutic use of these hormones in the present state of our knowledge is clearly indicated. For the rest the book remains much as it was. It undoubtedly gives what the authors have intended—namely, "a well-balanced account of modern thought and practice in gynaecology." We have no doubt that this edition will maintain the prestige which its predecessors have won.

The late Dr. G. M. Gould's *Pocket Pronouncing Medical Dictionary*⁸ of the principal words used in medicine and the collateral sciences now contains more than forty thousand words and tables of arteries, bones, muscles, signs and symptoms, metric measures, and doses of drugs. The latter based on the tenth revision of the *United States Pharmacopoeia*. To British readers it will probably be most useful in explaining the meaning of rare words and synonyms, and especially of eponyms, of which there is a truly formidable collection, many of them quite new to the reviewer. It is compact, easily carried in the pocket or bag, and capable of supplying information in the shortest possible time.

OCULAR HEADACHES

Ophthalmology, even when qualified as clinical ophthalmology, has obviously a wider range than the activities covered strictly by the term "ophthalmic surgery," and both studies and practice in this department have for the most part recognized that a broad outlook, rather than a restricted one, is necessary to meet alike the needs of the patient and the progress and extension of knowledge. In other words, pathological conditions in the visual apparatus often mean remote and sometimes detached consequences, or are part of a clinical picture that requires a wide and inclusive survey. In particular, there are areas where ophthalmology has a common frontier with general medicine, with neurology, with rhinology, and even with surgery, and the meeting along the boundary lines of representatives of the interests concerned may well mean mutual advantage and the settlement of doubtful issues. Recognition of these truths has not infrequently governed the arrangements of professional discussions with a view to secure both the presentation of the larger relations of ophthalmology and the consideration of these by practitioners who are not in a strict sense included within the technical ophthalmological ranks. Presumably motives of this order prompted the officers of the Section of Ophthalmology at the recent Annual Meeting to select as a topic for debate "Headache in Relation to Ocular Conditions," and the two opening papers of the discussion as printed in our present issue fully justify the choice.

In a preliminary remark Mr. Arthur Griffith expressed surprise that physicians so frequently fail to recognize faulty eye conditions as a cause of headache, and he quoted his own clinical records in support of his statement. The possible association between the two has often been affirmed, and, but for Mr. Griffith's challenge, it might have been regarded as accepted doctrine; and this all the more as it is difficult to imagine the absence of an ophthalmoscopic examination when the patient complains of headache, and, this position once reached, other ocular inquiries would seem to be almost inevitable. Perhaps the experience may be quoted as another illustration of the claim that even well-worn truths need occasional repetition and revival. When the existence of gross disease can be excluded it is principally in the direction of errors of refraction and of disturbed muscle balance that the source of ocular headaches is to be found. Of the former many are manifest when ordinary methods of testing are

applied, though it is important to note that, at least in the case of astigmatism, it is the minor rather than the major defects which give rise to headaches; in the one, compensation by ciliary effort is not attempted, for it would be in vain, while a relatively slight defect can be redeemed, though at the cost of effort, which in turn demands its penalty. Some few years ago it was not uncommon to hear of widespread and disastrous consequences attributed even to very minute degrees of astigmatism, and of the curative triumphs which correction of these secured. In these claims it would appear there must have been an element of exaggeration, for nowadays their advocates are by no means active. While errors of refraction as a cause of eye-strain and of consequent headache are within comparatively easy reach, the detection of imperfect muscle balance is often far from a simple matter, and may be secured only as a result of special experience. None the less it is a possibility that must be borne in mind, and this the more so seeing that, given an accurate analysis, the ability to provide relief is a fairly confident one. Mr. Griffith's remarks on this point have an eminently practical value.

The opening address presented two reasons why in the individual patient the possibility of eye-strain as a cause of headache is sometimes unrecognized. One is the fact that the symptom at times becomes troublesome, not when the eyes are actively engaged, but during or after a period of rest; and the other, the remote situation of the pain, as, for example, in the occipital muscles. The essential initial disturbance is excessive muscular contraction, and the delayed headache may therefore be regarded as comparable to other delayed pains which follow undue muscular stress. As an explanation of the occipital headache due to eye-strain Mr. Griffith suggests that for certain reasons patients acquire the habit of "screwing" their lids together: this means tension on the frontal muscles, and as these, through the epicranial fascia, pull on the occipital muscles there is stress on these muscles also, and consequently a condition of painful contraction. Whether this ingenious suggestion is or is not warranted, the fact of occipital headache under eye-strain illustrates the truth that not all headaches of ocular origin are referred to the eyeballs or their immediate neighbourhood. While it may be allowed that the primary source is strain in some part of the ocular musculature, the pain so produced may radiate over any of the branches of the trigeminal nerve, and occasionally, as just explained, be referred to the region of the occiput. With this generalization it is of course necessary to remember that not all pains or aches in these various regions are due to eye-strain, that even when eye-strain is part of the story it is not necessarily the whole of it, and that here as in other diagnostic ambitions it is the whole which must be known before a safe conclusion can be written.

Among other points of interest in the opening papers may be noted the conclusion that migraine, in spite of the suggestive visual disturbances which accompany it, does not depend on any refractive defect. Such defect may of course be present in a migrainous patient as in a non-migrainous patient, but little hope of relief can be placed on its correction. There are also neuralgias to which the same comment applies. One of these, named by Dr. Wilfred Harris "maxillary neurosis," is characterized by pain more or less persistent in the cheek and at the side of the nose and temple, and is almost peculiar to women; unfortunately it is very resistant to treatment, and neither operative intervention nor the injection of alcohol is of any avail. The possibility of pain, perhaps widespread pain, from acute glaucoma, and described by the patient as headache or neuralgia, is always a note in the practitioner's memory, and headaches as a prominent symptom of many general conditions are frequent experiences. What the present discussion emphasizes is that, when no obvious explanation presents itself, it is important, in face of a negative clinical examination, to remember that even though the history does not suggest the conclusion, eye-strain in one or other of its varied forms may supply the solution of the problem. Contributions from specialized departments of practice to the wider interests of general medicine serve the interest both of those who give and those who receive, and, still more important, they contribute to the welfare of patients.

INFERTILITY AND CONTRACEPTION

It may be of interest to consider together two recent publications: *The Twilight of Parenthood*,¹ by Dr. Enid Charles, and the fifth report of the International Medical Group for the Investigation of Contraception.² Dr. Charles's book is a brilliant and well-planned argument on a matter of great moment. If its facts, lessons, and conclusions could be brought home effectively to the statesmen, social workers, and people of Western Europe and America, it might prove epoch-making. The report, as Sir Humphry Rolleston says in his short introduction, is intended to give "an impartial summary of statistical and medical information about contraception as it becomes available in different countries." Dr. C. P. Blacker, who may be described as the editor of the report, and whom we congratulate upon the interest and value of its contents, says that "in the course of the last two years there has been observable a tendency for discussions on birth control to centre upon practical rather than upon moral issues," and with these practical issues most of the document is concerned. Information comes from Great Britain, from the United States of America, from Denmark,

from Germany, and from Russia. Probably the two most important sections are those which summarize books, or portions of books, by Dr. Enid Charles in this country, and by Professor Raymond Pearl in America, each published about two years ago. The German contribution to the report has a peculiar and immediate interest in that its author, Dr. Max Hodann, has had to leave Germany for Switzerland on account of his connexion with the birth control movement; he tells of the militant campaign against such control since the Nazis achieved power, and of the present position under their regime. The importance of the report as a whole, therefore, consists in the fact that it enables one to envisage in one fairly comprehensive view the existing actual practice of contraception over a considerable part of Western civilization, its methods, and the tentative results of those methods so far as they can be ascertained by imperfect means and with relatively small numbers.

The Nazi attitude, if credence is to be given to the public statements of more than one of its chief exponents, is not based upon any tenable biological considerations or on realization of a tendency towards underpopulation, but upon the desire to produce, in numbers preponderantly larger than other nations, male citizens who may in time be available for warfare. Professor Pearl states that "the mean number of pregnancies per white woman who practised contraception was 2.79; per white woman who did not practise it, 2.68. The mean number of pregnancies per negro woman who practised contraception was 4.15, and per negro woman who did not practise it, 2.94"—and this from as nearly random a sample of poor people as could well be obtained. Whatever weight may be attached to this finding, it is certain that the general advocacy and practice of contraception is based upon the opinion that large families are undesirable in themselves under modern conditions, and upon the belief that overpopulation is a national and world-wide danger. The untenable nature of this belief is demonstrated by Dr. Enid Charles. The title of her book, *The Twilight of Parenthood*, has the disadvantage of not indicating at once the nature of the subject dealt with. This may be stated broadly as the menace of underpopulation. "It unfolds the spectacle of a society which has lost the power to reproduce itself, is losing that power more and more, and must continue to dwindle unless a fundamental readjustment occurs within the human ecological unit." It is not, of course, an entirely new thing to expose Malthusian fallacies. A few of the papers and speeches made at the last International Population Conference held in London in 1931 were effectively directed towards this; but it was not a pronounced feature of that conference, and both biological and statistical advances have since then become more cogent.

The facts and arguments are marshalled by Dr. Charles in a masterly way and set forth in most interesting fashion. She shows, first, that the analogy with

¹ *The Twilight of Parenthood. A Biological Study of the Decline of Population Growth.* By Enid Charles, M.A., Ph.D. London: Watts and Co. (7s. 6d. net.)

² London: National Birth Control Association, 26, Eccleston Street, S.W.1. (2s.)

AUG. 18, 1934]

NEEDS OF THE UNEMPLOYED

biological conditions obtaining in regard to non-human species is vitiated by man's capacity to control both his own reproductive habits and the evolution of the animal and plant economy of which he forms a part. "The one thing man cannot avoid doing is interfering with the selective processes of Nature on a scale which no other animal has the power to do." Secondly, she shows by an amazing number of examples that there is, under modern conditions, no danger of food shortage even in a world with a population immensely larger than the present. "The world's food production could be increased many times without increasing the area of cultivation if mankind exploited to the fullest extent all the scientific knowledge at present available." Thirdly, she describes clearly and in relatively simple terms the new statistical methods of measuring fertility rates which we owe to Kuczynski. The gross reproduction rate is defined as the number of girl children likely to be born to a woman passing through the whole child-bearing period on the basis of the fertility rates prevailing in a given place at a given time. The net reproduction rate takes into account the probability of survival of such children to become future mothers. A population with a net reproduction rate of unity must, if rates do not change, soon become stationary. "A rate lower than unity means that a population is doomed to extinction"—again, if rates do not change. The United States, the British Colonies, and all Western European nations (including Germany and Italy) even now have rates below unity, and the rate is continuously diminishing. That of England and Wales is probably the lowest, at 0.75. "Once a stable age composition has been reached the population would be reduced to less than six millions in about 200 years. . . . If the rate were to fall further, say to 0.5, in the space of 300 years the population would be reduced to 45,000. . . . Our present knowledge makes such a possibility less incredible than any of the 'nightmares of population' which Malthus predicted."

In further chapters Dr. Charles discusses differential rates of reproduction between different classes of persons, and finds that apart from the fact that the urban rate is lower than the rural, any difference in rate between social classes is tending to disappear. Complete parity has in fact been reached in Stockholm. She deals also with the influence of contraceptive practice and technique, and with the physiological effects of civilized living, and finally discusses proposals for sterilizing defectives, and plans for "the reinstatement of the child in a planned economy." A point made by her is that it is the business of the biologist and scientific statistician to describe—perhaps sometimes to prescribe—but not to predict. We may be sure that all readers of her book will not be in full agreement with every suggestion made in the last chapter; but every reader must realize the great importance of the situation disclosed, must admit the force of the general argument, and must admire the ability with which the thesis is stated and supported.

NEEDS OF THE UNEMPLOYED

For some time now medical men and others who have interested themselves in dietetics have maintained that there are sufficient scientific data upon which to assess the minimum food requirements of the body, and that it is possible to translate those needs into pounds, shillings, and pence. As the cost of food consumed forms the major part of the outlay of any family near to or on the poverty line, the assessment of the cost of a minimum diet assumes great importance in the work of any public authority dealing with public assistance. In the past it has been the sociologist whose work has been accepted as the basis for calculation, and even to-day, in the recent social surveys of London and Liverpool, these same forty-year-old estimates, brought up to date as regards prices by use of the Board of Trade index, have been accepted as fundamentally sound. In future assessments it is essential that the estimates made by the British Medical Association's Committee on Nutrition,¹ or estimates based upon data provided by the joint conference of nominees from the Advisory Committee of the Ministry of Health and from the B.M.A.'s Committee,² be utilized. It will be remembered that the latter conference suggested greater latitude in interpreting the needs of the individual, and in some cases actually suggested an increase in the scale of allowances. A recent letter broadcast to the Press, lay and medical, signed, among others, by the President of the Royal Society, Sir Frederick Gowland Hopkins, who was chairman of the joint conference and is a member of the Ministry of Health's Advisory Committee on Nutrition, lays stress on the need for expert medical opinion in estimating "the minimum requirements of healthy living and the cost of satisfying them for families of various sizes."³ With this expression of opinion no medical man will disagree. The importance of such considerations at the present time lies in the fact that the new body, the Unemployment Assistance Board, has as its task to provide for the vast body of the unemployed according to their needs. The Minister of Labour who piloted the Bill creating this new board through the House of Commons stated that the function of the Board was "to meet the whole needs other than medical needs to the extent that the meeting of those needs requires."⁴ Clearly a standard of needs is essential to the fulfilment of the functions of the Board, and the major item of the standard is the figure for food requirement. How the other needs—fuel, clothing, cleaning, lighting, and rent—may be estimated, may be seen in a memorandum prepared by Miss Eleanor Rathbone, M.P., which has just been published.⁵ This is a very able summary of the functions of the Board, the pledges of the Minister in charge of the Bill, past and present estimates of needs, and suggestions for the future assessments of needs. Medical men interested in the physical welfare of the unemployed will do well to avail themselves of the valuable information and constructive suggestions so clearly set out in this memorandum.

OCULIST AND OPTICIAN IN EUROPE

Not long ago the secretary of the French Association of Oculists appealed for information as to the fields of activity of these workers in different countries. The matter was taken up by the Association Professionnelle Internationale des Médecins, which has issued in the *Revue Internationale* for May the answers obtained from seventeen European countries to a questionnaire entitled "The Position of the Optician *vis-à-vis* the Oculist, and the Attitude thereon taken by the Medical Organizations." There are, as might be expected, many divergencies in the answers, but the secretary of the A.P.I.M. states that there is "sufficient analogy in them to justify a serious attempt to clear up the veritable anarchy which exists to the detriment of all concerned." The questions asked dealt primarily with the training and examination of the optician, his legal position, and the relations between opticians and the medical profession. In seven countries there is organized education of opticians, in nine nothing more than apprenticeship. The length of education averages a little over three years. In only three countries—Austria, Belgium, and Great Britain—is instruction of a medical nature given. In most countries there is a diploma, and therefore an examination, but in Denmark, Spain, Luxembourg, Poland, and Sweden there is neither. A diploma is necessary for practice in Austria, Danzig, Germany, Hungary, and the Canton of Vaud, Switzerland. In Germany, Danzig, and Great Britain the diploma specifically permits the use of both subjective and objective methods of examination, whereas in Hungary and Canton Vaud the objective method is specifically excluded. The practice of sight-testing is open to anybody in all countries except Austria, Bulgaria, Germany, Norway, and Canton Vaud, where it is reserved for those who possess a diploma. In Germany opticians must not give glasses (except on medical prescription) to children and to persons suffering from disease. In Bulgaria and Danzig there must always be a medical prescription—though in Danzig the rule is said to be often ignored. In Hungary the optician can supply without prescription glasses up to 6 dioptries, but no compound lenses, and no glasses at all to children and old people. In Canton Vaud the optician may only use the subjective method of examination, and must not supply children under 16 except on a prescription. Only in Sweden does there appear to be anything comparable to our Association of Dispensing Opticians, whose members pledge themselves to supply glasses only on medical prescription, while nowhere does there exist any practical co-operation between doctor and optician like our National Eye Service. It seems, moreover, that Great Britain is the only country in which there is a rate- or State-provided eye service for school children, though Germany reports something of the kind at Berlin and Munich. Summing up the opinions of the various groups questioned, the secretary of the A.P.I.M. finds general agreement that the opticians should be "technical collaborators" with the oculist. France is prepared to co-operate with the optician on the basis of "monopoly of prescription by the doctor and of supply of glasses by the optician." Many groups would be prepared to give a higher degree of recognition to the optician in exchange for evidence of greater

competence on his part. Denmark would be satisfied if opticians were allowed to prescribe only plain lenses. There would seem to be a tendency to permit the provision of glasses by opticians if they were allowed only to use the subjective method of examination. But the case against this is well stated by the Swedish Medical Association,* as follows:

"From the point of view of treatment, errors of refraction should be regarded as diseases. . . . If one tried to regard some of these errors of refraction as 'non-maladies' it would be necessary to make exact discrimination between the different categories of errors of refraction, leaving the optician to treat a certain number. But that is impossible, for such discrimination can only be arrived at by very careful examination of the individual. That being so, it is charlatanism for persons without medical education to take on themselves the treatment of errors of refraction. The general rule that a medical practitioner should not collaborate with a charlatan applies to collaboration with an optician who treats errors of refraction, and, moreover, all advertisement by such people ought to be condemned by the medical profession."

EVIPAN ANAESTHESIA

The arrival of a new anaesthetic on the market is usually a source of interest to the medical profession as a whole and to surgeons and anaesthetists in particular. Evipan has been no exception to this rule, and, since its discovery about two years ago, it has had extensive clinical trial both here and on the Continent. For the most part its use has been confined to surgical procedures of short duration, and little effort has been made to prolong anaesthesia for operations lasting for an hour or more. The experiences of various Continental surgeons with continuous evipan administration should therefore be of interest. Drs. Jentzer, Oltramare, and Poncet,¹ working in Geneva, have recently published their results of seventy-two major operations performed under evipan. In order to prolong anaesthesia for as long as necessary they devised the following technique. Each patient was given an initial dose of the drug intravenously, the amount varying from 6 to 10 c.cm. The injection was given slowly, the time taken being from three to seven minutes. After injection the syringe was disconnected from the needle, and its place taken by an apparatus for supplying a continuous drip of hypertonic glucose solution. This served the double purpose of supplying glucose to the liver and keeping the lumen of the needle patent. At the first signs of returning consciousness 1 or 2 c.cm. of evipan were injected into the rubber tubing conveying the glucose solution to the vein. This usually prolonged anaesthesia for about twenty minutes, and was repeated as often as necessary. By this means they were able to perform a gastrectomy by Finsterer's technique in rather less than three hours and with a total dosage of 27 c.cm. of evipan. Throughout the operation the patient's arm was kept steady in an arm-rest, and the needle was kept in position in the vein by means of an armlet. All the patients were given a preliminary injection of omnopon, which was repeated after the operation if the patient showed signs of restlessness. Some of their earlier cases required a few whiffs of ether to supplement anaesthesia, but with

* *Presse Médicale*, April 25th, 1934, p. 668.

increasing experience this became unnecessary. Drs. Menegaux and Secheyaye¹ have copied this technique in about seventy cases with satisfactory results. They also regard it important to give the initial injection slowly—1 c.cm. in approximately one minute. As soon as the patient's jaw relaxes a note is made of the quantity already injected, and a similar amount is again given at the rate of 1 c.cm. in thirty seconds. The rest of their technique is similar to that of Jentzer and his colleagues. Both sets of workers are satisfied that the method is safe in careful hands, and if it is not used in patients with hepatic disease. They both agree that from an operative point of view ano-rectal cases are the least satisfactory for evipan anaesthesia, owing to the occurrence of jerky movements of the legs. No untoward happenings were recorded, and the length of time for recovery after the anaesthetic was roughly in proportion to the dose of evipan injected. It would thus appear that short duration of anaesthesia, which has been one of the chief drawbacks to the use of evipan in major surgery, has now been successfully dealt with. Whether or not it will be used more widely on that account remains to be seen. There will no doubt be many who hesitate to give every surgical patient 20 to 30 c.cm. of a powerful barbiturate as a routine. Evipan deaths when they occur are not always explicable. Duboucher and his colleagues in Algiers recently gave a patient aged 60 about 5 c.cm. of evipan for the cure of a hydrocele. The operation was performed without difficulty, but the patient did not regain consciousness, and died twenty-two hours later. This was their sole death in 102 cases. They found evipan useful for Mohammedan patients, who regard inhalation anaesthesia as allied to intoxication, which is forbidden by the Koran—a point that may be noted by those who practise in the East, but is scarcely of importance to anaesthetists in this country.

SWIMMING BATHS

It is both seemly and hygienic that the water of swimming baths should be maintained in a condition approximating to its native purity. Since the ideal plan of constant replenishment, as in the case of a running river, is, on the ground of expense, excluded on the large scale, recourse is now usually had to the use of re-circulated water which is at the same time submitted to a process of continuous cleansing. A good account of the plant employed for this purpose is contained in the second edition of the work on swimming-bath water by Messrs. Wilkinson and Forty.² The next step is the removal of large objects by means of a strainer. Next, after the addition of aluminium sulphate, the water is passed through a mechanical filter—for the most part of the pressure type—at the rate of 250 gallons or more per square foot per hour; after filtration comes aeration to restore brightness and sparkle. The revived water is then subjected to the bactericidal action of chlorine gas, or alternatively

chloramine, ultra-violet radiation, or catadyn silver. It is not enough, as in the purification of drinking-water, that the bactericidal substance should be designed to kill off all germs in the water at the time of dosage. It must be administered in such excess as will destroy also those added to the water after its return to the bath. In the case of chlorine a residual concentration of 0.2 to 0.5 part per million is believed to be sufficient. The final procedure, before returning the water to the bath, is to re-heat it to, say, 72° F. In later sections of Wilkinson and Forty's book the chemical and bacteriological characters of bath waters are considered, and reference is made to the determination of alkalinity with a view to filtration and to the estimation of residual chlorine by means of the orthotolidin test. The chapters on construction and management are full of useful practical points. The book is recommended, for information and guidance, to medical officers, engineers, borough surveyors, sanitary inspectors, and all who directly or indirectly may have to do with the provision or control of swimming baths.

THE DEPRESSION AND HEALTH IN THE U.S.A.

The annual report for 1933 of the Surgeon-General of the Public Health Service of the United States¹ contains a note on the effects of the economic depression upon health. For several years past the Office of Statistical Investigations has obtained provisional mortality data from State health departments as a current index of the nation's health. Mortality has been decreasing in almost every State, but mortality in the general population does not truly reflect all the unfavourable factors. No change in mortality would be expected in that part of the population which is still employed: "the health of the unemployed is the real matter to be considered, and sickness is a better index of health than mortality." Information about sickness and deaths in a group of families was collected by house-to-house canvass and studied in co-operation with the Millbank Memorial Fund. A four-year history of employment and income and a three-month illness record permitted a comparison of families whose heads had been out of work for one, two, three, or four years with those not affected by unemployment. About 1,000 families were canvassed in each of ten localities, including eight large cities and two groups of villages. Communities were chosen that had been hard hit by the depression, and within the city the districts with the most unemployment and relief work were surveyed. Slum areas in which the "chronically poor" would be found in large numbers were, however, omitted from this survey. Within the selected sections every family was included, both employed and unemployed. Preliminary results indicate higher sickness rates among the poor, particularly in the case of the more serious illnesses that cause inability to work or confine the patient to bed. It appears also that families who were moderately comfortable in 1929 but who had been poor for two or three years suffered more from sickness than those who had only lately become unemployed and poor, while those now poor who formerly lived in moderate comfort reported more sickness than those who had been poor during the whole four-year period.

ONE HUNDRED AND SECOND ANNUAL
MEETING

of the

British Medical Association

HELD AT BOURNEMOUTH, JULY, 1934

THE SECTIONS

SUMMARY OF PROCEEDINGS

During the next few months there will be published in the BRITISH MEDICAL JOURNAL the opening papers communicated to the Scientific Sections of the Annual Meeting at Bournemouth. The reports of discussions in this and previous issues are intended to give members who were not present a general idea of the proceedings.

SECTION OF MEDICINE

Friday, July 27th

OEDEMA—ITS CAUSATION AND TREATMENT

With Professor J. G. EMANUEL (Birmingham), a Vice-President, in the chair, Dr. T. IZOD BENNETT opened the discussion on the causation and treatment of oedema.

Dr. Bennett said that the two main factors governing the passage of fluid from the capillaries to the tissue spaces were the intracapillary pressure and the colloid osmotic pressure of the plasma proteins. The intracapillary pressure was probably little affected by the arterial tension, but was easily increased by rise in the venous tension in any condition of back-pressure. As Starling had shown forty years ago, colloid osmotic pressure was of supreme importance, and was a constant drag on the passage of fluid into the tissues. Diminution occurred whenever there was loss of protein from the blood as in the case of extreme albuminuria, the loss of albumin being much more effective than loss of globulin. Increased permeability of the capillary wall was undoubtedly a factor in some cases, especially in urticarial conditions, but by itself it would not necessarily produce oedema. Sodium chloride had long been recognized as important: it had much to do with determining chronicity, but there was no group in which it was the predominant factor. It was the sodium ion and not the chlorine ion that was significant, and treatment must be based on these considerations. In cardiac oedema the main indication was to assist the output of the right ventricle. Rest was essential, and in the presence of auricular fibrillation digitalis was most valuable. Fluids must be strictly limited, and the diet should be free from salt. Careful comparisons of the fluid taken and urine excreted were a great help in control. Where these measures failed the mercurial diuretics, particularly salyrgan, were invaluable. In acute pulmonary oedema morphine and prompt venesection were often life-saving. The renal oedema which occurred as a terminal event in chronic nephritis was often due to cardiac failure; there was no renal failure. In such cases there was no contraindication to salyrgan. In the oedema that characterized the so-called nephrosis there was heavy albuminuria of long standing with reduction of plasma protein, but none of the changes in blood chemistry indicated renal failure. Here a high protein diet, particularly vegetable protein, was called for, and water and salt were to be strictly limited. Salyrgan was not contraindicated as a rule, but it must never be given in the presence of any indication of a progressive renal lesion. In acute and subacute glomerular nephritis the treatment was entirely different. With such progressive lesions all strain on the kidney must be avoided, and in acute cases complete

starvation was the ideal treatment. By limiting fluids to 20 oz. and food to small amounts of fruit, remarkable recoveries were to be achieved.

Dr. A. W. STOTT discussed the treatment of cardiac oedema. The diagnosis, he said, was usually simple, for there were always concomitant signs of general venous engorgement, and obvious evidence of myocardial failure. First thoughts must clearly turn to preventive treatment, but there was rarely any clue to the factor that precipitated failure in a heart that had hitherto maintained its extra burdens. Increasing dyspnoea, however, was a danger signal, and indicated the need for rest. Oedema itself, in its mild form, cleared up with rest and digitalis, and required no special treatment. In severe cases and in congestive failure with normal rhythm digitalis might give no great help; complete rest was essential, and this might be more easily obtained if the patient sat up in a chair rather than in bed. Food should be given in small and easily digested meals, and fluid and salt should be restricted. The saline diuretics were of little value, and those of the xanthine group were uncertain. The most satisfactory results were obtained from the mercurials, especially salyrgan, which should be given preferably intravenously. Treatment did not end with the relief of oedema, and borderline cases were considerably benefited by continued "prophylactic" doses of salyrgan.

Dr. H. GAINSBOROUGH said that the renal condition in which oedema was most evidenced was the so-called nephrosis. This conception had led many to regard the oedema as of extrarenal origin. In his view the condition was really an inflammatory one. In subacute and chronic cases the toxic-infective process was mild though persistent, the renal changes were slow and progressive, and the tendency to oedema might last for years. The toxic-infective process also exerted a selective action on the renal parenchyma, and in the end there might be nitrogen retention, hypertension, and death in uraemia. In acute nephritis the changes were rapid, and the condition resembled that in chronic nephritis after the tendency to oedema had disappeared. The treatment of oedema consisted in fluid and salt restriction, diuresis, and mechanical means, in that order. The best diuretics were urea, acidosis-producing salts, and salyrgan; the latter acted as a renal poison, and in renal oedema was only to be used in cases of dire necessity. The chronic underlying disease must be treated by diet, sun, air, and warmth; food must be ample, and nitrogen intake adequate for the body's needs. Healthy sanatorium life might sometimes bring complete recovery, even in severe cases.

Dr. GEOFFREY EVANS pointed out that oedema in nephritis might assume a variety of forms. In some cases it appeared in the cardiac form; in others there was evidence of a tissue metabolism factor in the symptoms of subthyroidism; while in others there might be indication of the distribution of angioneurotic oedema. In the cardiac form digitalis was of real value, and in some acute cases the results of venesection were dramatic. Thyroid extract might bring relief in subthyroid conditions, and in the toxic cases starvation, as recommended by Dr. Bennett, might be of great benefit. In every case of renal oedema, whatever the type of renal disease, it was essential to watch for all the known causes of oedema. The persistent oedema that accompanied nephrosis afforded opportunities of trying various remedies and also of noting their ill effects. Salt restriction, so valuable in many cases, was sometimes intolerable, and led to acidemia and uraemia. Salyrgan, too, must always be used with caution.

Dr. J. MAXWELL discussed briefly the chief factors in the causation of oedema of any type, with particular reference to the localized oedemas. In this group the chief instances were acute inflammation, the urticarial conditions, and some renal cases. In the urticarial group it was probable that the capillaries in the affected area were temporarily more permeable, and the phenomena were very like those which followed intradermal injections of histamine. It had been suggested that urticarial and angioneurotic oedema were the result of the local liberation of a histamine-like substance. In cases of angioneurotic oedema injection of adrenaline into the swelling often proved effective. Protein shock and autohaemotherapy were also successful sometimes, but the condition

AUG. 18, 1934]

was apt to recur. Cases in which specific desensitization was successful were, unfortunately, rare.

Dr. F. C. BOTTOMLEY (Bournemouth) drew attention to the old-fashioned remedy of heat, and cited a case—that of a child—in which hot-air baths had been rapidly followed by increased urinary output and diminution of oedema, with ultimate complete recovery. Professor Langdon Brown confirmed Dr. Bottomley's experience, and suggested that the effect of hot-air baths depended on the removal of salt from the tissues in the sweat. Analysis of the sweat lost showed a high content of sodium chloride. In cases which responded to fruit juice and glucose in acute gressively lower temperatures in the bath. He also advocated a diet restricted to fruit juice and glucose in acute nephritis. Dr. E. L. SERGEANT (China) asked whether the examination of the blood calcium would be of any help, and suggested that the administration of parathyroid and calcium might be a rational treatment. Mr. N. E. WATERFIELD (Great Bookham) advocated the use of auto-haemotherapy in the urticarial conditions. Dr. W. N. LEAK (Winsford) asked whether there was any evidence of vitamin deficiency in any of the forms of oedema that had been discussed. Dr. JOHN PARKINSON was unable to agree that rest, obtained by sitting in bed. Morphine might help to make rest in bed easier. "Dropsy" was a word of evil import to the layman, and it was therefore upon the patient the essential need for rest. Digitalis was not to be restricted to cases of auricular fibrillation; it was of great value in oedema with a normal rhythm, and its regular use in suitable cases helped to postpone the occurrence of oedema.

SECTION OF SURGERY

Friday, July 27th

HERNIA OPERATIONS

With the President, Professor G. GREY TURNER (Newcastle-on-Tyne), in the chair, Mr. C. MAX PAGE read a paper on physical efficiency after operations for hernia.

Mr. Max Page based his remarks chiefly on inguinal hernia. The practical surgeon, he said, would in the first place wish to determine the type of operation most likely to give a lasting cure. Radical cures were put first on a sound basis by Bassini, and his method and the others that followed were based on obliteration of the musculature of the canal. The next important advance was the use of fascial grafts and sutures. In spite of the amount of consideration given to the subject no common standpoint as to the best methods and their effectiveness had been reached. This was largely due to the lack of proper follow-up systems. Most surgeons were satisfied with their results, but he thought that a more critical follow-up would show a much higher recurrence rate than was imagined. Block's figures, based on the work of 650 different German surgeons, showed a recurrence rate of 4.2 per cent., employing the Bassini operation in over 13,000 cases. Block considered constitutional defect and poor tissue as the chief cause of failure, closely followed by suppurative and haematoma. He (Mr. Page) agreed with Block that the recurrences after operations for inguinal direct hernia were of the nature of internal direct hernias. Block, again, had found no definite ratio as to recurrence depending on the duration of recumbency after operation, or any relation between recurrence and the suture material employed. Mr. Page thought Block's figures, while valuable, were too comprehensive in assessing recurrence in adult inguinal hernia, since, by common consent, cure in women and children reaches a very high mark. American figures were even more optimistic. He (Mr. Page) himself assessed the recurrence rate in a healthy body of men, the Metropolitan Police, to be as high as 20.2 per cent. for indirect hernia and 25 per cent. for direct hernia. Whilst not sufficient time had elapsed for a clear assessment, it appeared that the use of fascial grafts and sutures were valuable in direct recurrence indirect hernias. His conclusions were that recurrence after operation in the young to middle-aged was much

commoner than was supposed. Whether this state of affairs was due mainly to differences of technique, failures of technique, post-operative complications, double hernias, or to hereditary or congenital weaknesses he was uncertain, and hoped that successive speakers would elaborate their opinions.

Mr. GEOFFREY KEYNES said that, practically speaking, there were few hernias for which cure should not be attempted. All recurrences were due to a failure of technique, and this in turn was largely the result of surgeons being too standardized in their methods. In this connexion a prolific cause of recurrence was the performance of the same operation after direct and indirect hernias. Physical efficiency after operation therefore depended on the surgeon having at his command an operative repertoire equal to dealing with every situation. The difficulties due to age or bronchitis could be circumvented by a varying anaesthetic technique. Mr. Keynes then showed slides illustrating all types and degrees of hernia.

Mr. HINDMARSH (Newcastle-on-Tyne) had investigated a series of 154 hospital cases. In 102 cases of inguinal hernia eighty-nine were completely cured; nine had recurrences (five bad and four slight); and four had pain in the scar. In thirteen cases of umbilical hernia eleven were completely cured, one had recurrence, and one complained of a painful scar. Of thirteen cases of ventral hernia eight were completely cured, four had recurrence, and one had a painful scar. Of twenty-six cases of femoral hernia twenty-three were completely cured, two had recurrence, and one had a painful scar. Workers in warm atmospheres, such as miners, found trusses unbearable, and demanded operation. He considered post-operative suppuration the chief cause of failure.

Mr. E. M. COWELL (Croydon) advocated wide resection of the hernial sac, taking away as much slack peritoneum as possible and covering the weak hernial opening with suitable fascial flaps, using fascial sutures. Mr. PHILIP TURNER, whilst agreeing that removal of the sac was essential, said that it was almost equally important to repair the defect in the transversalis fascia in adult cases. He had achieved this by, after removal of the sac, turning up a pedunculated flap under Poupart's ligament into the inguinal canal, and suturing it to the margins of the opening in the fascia. He had operated upon about one hundred patients by this method, with two small recurrences. Mr. McADAM ECCLES did not think that a truss, when such treatment was indicated, was a nuisance if properly made and properly applied. Speaking as an older surgeon, and referring to working-class adult cases, he doubted if selection of the type of operation was as important as attention to detail in asepsis and care in breathing exercises. Mr. WOOD POWER (Hereford) was not impressed with the fascial graft methods for ventral hernia. He split the rectus muscle obliquely and slid the anterior portion over to the mid-line. Mr. P. H. MITCHNER stated that because in adults there was a failure of the musculature of the inguinal canal to shut on exertion, post-operative recumbency after repair, best done by fascial graft, should be for at least three weeks. Thereafter strain or exertion should be avoided for three months. He considered the recurrence rate after any operation for femoral hernia was 5 per cent. Dr. JOHN RAMSAY (Launceston, Tasmania) supported the use of kangaroo tendon sutures. Professor A. W. SHEEN (Cardiff) said recurrences were mainly due to failure of removal of the deepest part of the neck of the sac by inexperienced operators. Mr. BLAIR (Hull) was in favour of three weeks' hospital convalescence after operation. Mr. MAX PAGE, replying, said the discussion had shown great variation on the points of technique, on the importance of technique, on the question of how long the patient should remain recumbent after operation, and on the importance of the various causes of recurrence. All the opinions expressed could not be right, and the subject could only be clarified by the adoption of proper follow-up systems.

SECTION OF OBSTETRICS AND GYNAECOLOGY

Friday, July 27th

DIATHERMY CUTTING CURRENT IN CERVICITIS

With Mr. S. GORDON LUKER (Bournemouth) in the chair, Mr. J. C. AINSWORTH-DAVIS read a paper on "The Treatment of Chronic Cervicitis by the Diathermy Cutting Current."

Mr. Ainsworth-Davis said that the palliative treatment of this condition was seldom successful, and surgical measures were more reliable. His own method was to remove the glandular tissue of the cervix with a wire loop, which was used as the diathermy cutting knife. A non-inflammable antiseptic must be employed, and the curette must be passed at least a quarter of an inch beyond the internal os. The loop was so constructed that the correct depth of tissue was removed in strips. There was no bleeding. If an erosion of the cervix was present deeper strips of tissue must be removed. The speaker illustrated his apparatus and his discourse by means of lantern slides. No distortion or contraction of the cervical canal occurred, but no opinion could be given as to the results the treatment would have on conception and pregnancy. Following treatment in one case the patient became pregnant for the first time after twelve years of married life. The subsequent pregnancy was normal. Chronic cervicitis was a common cause of infection of the urinary tract, and as such should first be treated. The strength of the current was adjusted to dial setting 4 on the genito-urinary endo-diathermy machine.

Mr. ALECK BOURNE said he had used the method described, and had experienced difficulty in controlling the depth of the cut. He also found that the bleeding was severe. Mr. W. S. RICHARDSON (Bournemouth) said that in his experience the immediate results of treatment were extremely good. Drs. H. J. McCURRICH (Hove) and L. M. JEFFRIES (Hove) also approved of the method. Dr. DUGALD BAIRD (Glasgow) doubted that chronic cervicitis and a chronic urinary infection could be so closely associated as had been suggested. Mr. S. GORDON LUKER (Bournemouth) expressed doubts as to whether the method might not interfere with the likelihood of ensuing pregnancy.

In reply, Mr. AINSWORTH-DAVIS said that the depth of the cut was judged by experience: dryness of the cut was ensured by the slowness with which it was made.

PYELITIS OF PREGNANCY

Dr. DUGALD BAIRD, in a paper entitled "After-histories of Pyelitis of Pregnancy, with Special Reference to Subsequent Pregnancy," stated that 208 cases of pyelitis of pregnancy had been studied over a period of one to five years, of which seventy-four had had no subsequent pregnancy. Fifty-two per cent. of those did not feel well, and 47 per cent. still had infected urine. Some of the cases with persisting infection of urine felt well, and some of those with sterile urine did not. Urological examination showed that in many cases there was permanent damage to the kidney substance, usually the right. Symptoms complained of were renal pain or pain along the ureters, usually worse before the menstrual period. Of the 134 patients who had experienced subsequent pregnancy, eighty-seven had had one, with pyelitis occurring in forty-six, and thirty-two had had two, fourteen of whom had had pyelitis with each pregnancy. As a rule, if the urine was sterile before the onset of a second pregnancy pyelitis would not recur. If the urine was infected an exacerbation would often occur, and this depended largely on stasis in the ureters. The exacerbation was practically always less severe than the original attack. In some cases the infection became less severe with succeeding pregnancies, and disappeared spontaneously. In others the infection persisted, giving rise to stricture, haematuria, calculus, and occasional accidental haemorrhage and uraemia. In a number of these cases termination of the pregnancy and subsequent nephrectomy had been required. (Dr. Baird illustrated his paper with lantern slides.)

Mr. GORDON LUKER said he had the impression that pyelitis had recently appeared to be less severe, and was frequently associated with toxæmia of pregnancy. Mr. CARNAC RIVETT thought that the condition was increasing in severity: he advised termination of pregnancy in cases that failed to respond to medical treatment. Dr. E. M. TOWNEND (Hull) had also terminated the pregnancy in a number of cases. Dr. R. A. R. WALLACE (Bishop's Stortford) felt that the condition occurred largely as a result of excess of carbohydrate.

In reply, Dr. BAIRD stated that induction of abortion was required in those cases which failed to respond to standard treatment: usually these were left far too long before the pregnancy was treated.

A CHLOROFORM INHALER

Mr. R. CHRISTIE BROWN described a simple chloroform inhaler for use in normal midwifery. This apparatus was first designed for those patients whose confinement was conducted by midwives.

Mr. Christie Brown thought that his inhaler was simple in use, cheap to manufacture, and could be administered by the patient. The principle was that of the unspillable inkwell. The inhaler was enclosed in a linen bag to prevent the chloroform splashing out. The air breathed was passed over, and not through, the chloroform. The inhaler had been tried out on 800 cases at the City of London Maternity Hospital, with considerable success. A mask which could be fitted to the instrument was demonstrated.

Mr. A. J. WRIGLEY felt that Mr. Christie Brown had produced an inhaler that was a great improvement on the capsules of chloroform. Mr. CARNAC RIVETT wondered why midwives should not be allowed to give anaesthetics. He thought that with adequate training they would do so safely. He also felt that the inhaler was an improvement on the capsules.

UTERINE RETROVERSION

Mr. GORDON LUKER read a paper on "Retroversion of the Uterus." He said that gynaecologists taught that mobile retroversion needed no treatment: he disagreed with this teaching. A congenital retroversion in a nulliparous woman seldom required treatment. In a married woman this condition might give rise to dyspareunia. Retroversion acquired after miscarriage or labour certainly did require treatment. This occurred in as little as 13 per cent. of primiparae. Failure to correct the retroversion in these cases led to a likelihood of prolapse. Backache was experienced, which was relieved by rest. Lastly, a group of cases was found in which the malposition was discovered at some distant time after childbirth. Retroversion with dyspareunia should be corrected by manipulation, but frequently it was impossible to maintain the anteversion with a Hodge pessary. Failure usually indicated operative treatment. Preventive treatment should be first used in acquired retroversion. A prone position should be adopted for at least two hours a day in the puerperal woman. The patient must have a post-natal treatment one month later, and the malposition corrected. The speaker preferred the Hodge pessary to the rubber ring pessary. Operative treatment was especially indicated when the uterus was fixed and the prolapsed ovaries were tender. An inquiry from the senior gynaecologists at the London teaching schools indicated that operation for the condition was seldom indicated or performed. The operation of choice was that described as a modified Gillian's operation.

Mr. R. CHRISTIE BROWN said that he had examined 1,000 women after confinement, and found only fourteen who had a retroverted uterus. No treatment was instigated, and in six months' time seven only had a retroverted uterus. He did not believe retroversion caused the symptoms associated with "uterine congestion." Dr. A. BLOOMFIELD said that most relief was gained when, at the operation for retroversion, other complications were found. Dr. CHISHOLM (Dundee) agreed that retroversion caused symptoms, and that alleviation of these symptoms occurred after operative correction. He did not think that retroversion predisposed to prolapse. Dr. HURTON

THE SECTIONS: SUMMARY OF PROCEEDINGS

AUG. 18, 1934]

(Orpington) had come to believe that retroversion caused more symptoms than was usually thought to be the case. He felt that postural treatment in puerperal women could not receive sufficient stress.

THE PROLAPSE SYNDROME
Mr. A. C. PALMER read a paper entitled "The Prolapse Syndrome: Its Treatment by Vaginal Hysterectomy, with Reconstruction of the Pelvic Diaphragm," with cinematograph demonstration.

The speaker said that when prolapse occurred in women who, in addition, had excessive uterine haemorrhage, the term "prolapse syndrome" was used. Usually two severe operations were required to deal with this syndrome. Mr. Palmer said that the combined operative treatment had been performed by him on sixty-two occasions. Urinary infection was common. It occurred in seventeen cases, but was less likely if a self-retaining catheter was employed. Secondary vaginal haemorrhage was seldom to be seen if the vagina was treated with a daily antiseptic douche. Before the operation was attempted the cervix should be mobile. The operation consisted of anterior colporrhaphy, hysterectomy, posterior colporrhaphy, and perineorrhaphy. He then illustrated the operation with a film to an admiring audience, who, if they were critical of its necessity and of the severity of the operation, were unstinting in their praise of the demonstration.

SECTION OF NEUROLOGY, PSYCHOLOGICAL MEDICINE, AND MENTAL DISEASES

Friday, July 27th

THE MECHANISM OF PAIN

With Mr. NORMAN DOTT (Edinburgh), a Vice-President, in the chair, Professor DAVID WATERSTON (St. Andrews) opened a discussion on pain.

Professor Waterston said that the mechanism of pain production was as yet unknown. We did not realize with certainty whether the thalamus was the centre—if indeed there was a "centre"—nor what the effective structures and end-organs in many structures were. Different structures had very different sensitivity to pain—for example, the skin and the alimentary canal. He believed the problem of the mechanism of pain in the viscera would not be solved until we knew more about its mechanism in the somatic tissues. He referred to his own experiments in which various tissues were tested with nerves and needles. The epidermis was well supplied with nerves and had many free nerve endings, yet it was not sensitive to pain. Its nerves might be injured or divided without pain resulting. The dermis gave an acute pain response; subcutaneous tissue was relatively insensitive; acute pain was caused by the passage of the needle through the fibrous aponeurosis of a muscle, but in the muscle tissue proper the sensation was a dull feeling of pressure. Pricking the wall of a vein usually caused little pain, but with arteries the pain was immediate, severe, and sickening. Pain arose from muscles which contracted without adequate blood supply, and Sir Thomas Lewis had discovered that there was produced locally in the muscle a chemical stimulus which he called the "p substance." Professor Waterston believed that some such substance was probably responsible for pain in other tissues too. "Referred," or, as he wished to call it, "heterotopic," pain might be abolished by the injection of local anaesthetics at its site, and it had been found that a similar result followed the injection of normal saline. This suggested that even "referred" pain might be due to a "pain substance" produced in the tissues.

Mr. JOHN MORLEY (Manchester), dealing with abdominal pain, said it was well known that while the gastrointestinal tract was insensitive to mechanical stimuli such as pin-prick, the peritoneum was very sensitive. He did not believe in the viscerosensory radiation of gastrointestinal pain in Mackenzie's sense. Every surgeon knew that in acute appendicitis the inflamed appendix would be found under the site of maximum tenderness, and this was variable, whereas the site of theoretical referred pain was fixed. He believed the pain was produced not from

the viscus but from the overlying peritoneum, and it was radiated to the more superficial sensory branches of the somatic sensory nerves which supplied the peritoneum.

Dr. MACDONALD CRITCHLEY, speaking of the psychological aspects of pain, said that preoccupation with the pain was constant, but other concomitants depended on circumstances. The sufferer's sense of time was disorganized. Depression was unusual. In rare cases there was stimulation of the special senses, especially the colour sense. He also spoke of the variations in susceptibility to pain. Refinement and education increased it, and on the other hand there were rare individuals who seemed to be devoid of all susceptibility to pain. One such man exhibited himself as the "human pin-cushion." These persons experienced at most a mild discomfort when needles were stuck into them, and they allowed their teeth to be extracted without anaesthetics of any kind.

Dr. H. CRITCHON-MILLER said that, while pain might be a definite form of sensation, different experiences, and the doctor's responsibility was to relieve whatever the patient complained of as pain. The fact that the patient confused a definite form of sensation with the subjective manifestations of mental conflict was not relevant. When a boy ate green stolen apples there might be both physical and mental resultant reactions—gastro-intestinal pain and fear of punishment—and confusion resulted in the boy's mind. It might be protracted subjectively, and similarly pain might occur as a reaction to any "shame unpublished." In other cases the complaint of pain was calculated—unconsciously—to secure an environment or promote a form of behaviour only appropriate to a less mature individual. Again, the evasive purposes of psychogenic pain might be very far-reaching.

Dr. T. GWYNNE MITLAND (Liverpool) said that as a result of conditioned reflexes neutral stimuli might be welcomed with signs of pleasure or received with signs of pain. This showed the adaptation of the organism, and there appeared to be no limit to the possibilities of "substitution phenomena." By frequent exposure to pain the threshold was apparently raised, as in the prize-fighter or the Indian fakir. The ecstasy of the martyr was explained by distraction, and this accounted also for the discomfort the football enthusiast would endure. Conversely, aggravation occurred. A mother's distress at a child's scratch or bloody nose made the child apprehensive. Soothing words and cuddling were not calculated to raise the child's endurance of pain. The Spartan mother made men of her sons, and this was not done by neglect. Those who had charge of children should give the hurt child merely what attention was necessary for remedial demands, and pain that was inevitable would then have its proper place.

Dr. J. PURDON MARTIN discussed the features and mechanism of certain forms of pain in organic nervous disease. There were no end-organs for the reception of pain stimuli in the central nervous system, and pain resulting from nervous lesions was apprehended pathologically as a result of lesions of the conducting system. The signs and symptoms in cases of lesions of the thalamus constituted the most remarkable pain syndrome in medicine. It consisted of spontaneous pain together with a peculiar over-reaction to pain stimuli. A similar reaction occurred during the recovery of divided nerves, and it began about ten days after the injury, which was roughly about the same time as changes might become apparent in the central cells. In trigeminal neuralgia we encountered pains that were excited by stimuli which were not "pain stimuli"—for example, light touch and muscular movement. The most intense experimental stimulation of touch organs did not give rise to pain, and he suggested that in neuralgia there must be an escape of impulses from one kind of nerve fibre to another.

In discussion, Dr. LIONEL WEATHERLY (Bournemouth), the President of the Section, described a case in which a woman committed suicide by covering herself with burning coals. Drs. MURDO MACKENZIE, J. S. MANSON (Warrington), E. FALKNER HILL (Manchester), and C. W. HUTT having spoken, Professor WATERSTON replied to the points raised in the discussion.

SECTION OF PATHOLOGY, BACTERIOLOGY,
AND BIOCHEMISTRY

ANTISEPTICS IN CONTROL OF BACTERIAL INFECTIONS

With the President, Professor J. W. BIGGER (Dublin), in the chair, Professor C. H. BROWNING (Glasgow) opened a discussion on the value of antiseptics in the control of bacterial infections.

Professor Browning said that so far as ordinary bacteria were concerned success could only be looked for at present when the drug could be brought into close contact with a localized infection in a wound or cavity. Lister had used antiseptics primarily to prevent the access of organisms to wounds, and, though he applied carbolic acid to the soiled tissues of a compound fracture, he fully appreciated the harmful action of the antiseptics then known on living tissues, and never applied them to abscess cavities. The need of new antiseptics which would not damage tissues was therefore manifest. Professor Browning described the curative value of antiseptics on artificially infected wounds in guinea-pigs. The antiseptic was applied three-quarters of an hour to two hours after the infecting organism, and for a very short time. Of twenty-two such animals treated with acriflavine all but one survived, while five out of seven treated with phenol died, and fourteen treated with normal or hypertonic saline all died. Similar results had been obtained by other observers in skin wounds in mice. Even artificial infection of the mouse's peritoneum had been treated with some success by intraperitoneal injection of acriflavine up to an hour after infection. Local suppression was difficult to produce in laboratory animals and human results were difficult to control, but Graham had shown, in a case of multiple burns in the human being, that those dressed with acriflavine healed more rapidly than controls dressed with wet boric lint. No known antiseptic would sterilize infected kidneys, but of acriflavine combined with alkalinization. Sterilization of bile passages and of the meninges by antiseptics had not yet been achieved, and attempts to modify the intestinal flora had also been unsuccessful. No success had been achieved in curing generalized infections, with the sole exception of pneumococcus septicaemia in mice, which had been cured by optoquine. Professor Browning then discussed the characteristics required in an antiseptic. Rapidity of action was not essential, and organisms, though still viable, might be modified by the antiseptic so as to become susceptible to the defence forces of the host. An important property of some of the new antiseptics was that they retained their full activity in the presence of serum, and were not fixed by the tissues. Some of the new antiseptics were also distinguished by the high concentrations which could be used without causing tissue damage.

Dr. R. J. V. PULVERTAFT said that success in chemotherapy was more likely to follow research into bacteriostatic than into bactericidal values of antiseptics. Bacteriostatic values varied with the phase of growth of the organism, and a concentration which was effective if added before inoculation might be almost without effect if added in the phase of positive acceleration. There was need of standard strains of a number of organisms against which antiseptic activity could be measured. There was salts were useless in generalized infection; and so-called pyelitis was rarely benefited by so-called urinary antiseptics. Dr. G. W. THEOBALD said that we knew very little about the virulence of organisms or the resistance of patients, nor did we know how antiseptics acted. Bolton and Brown's experiments with heavy metals made former views untenable. In the body quinine killed malarial parasites, and emetine the *Amoeba histolytica*, in concentrations far below those necessary *in vitro*. This suggested that the best results would be obtained when the antiseptic reacted with the tissues to make the environment unfavourable to bacteria. Neither life nor antiseptic activity was purely a matter of physics and

chemistry. Dr. Theobald believed that puerperal pyrexia could be stamped out by free use of 1 in 1,000 solution of mercury biniodide, and that intravenous mercurochrome was of value in blood infections with the coli-typhoid group of organisms.

Dr. M. SYDNEY THOMSON, after discussing the work of Selli, Cornbleet, Hill, and White on the antibacterial properties of the normal skin, referred to certain applications of dermatological interest. Trichloroacetic and salicylic acids, zinc oxide, and ichthylol were dealt with. He mentioned the possibilities of interaction between chemicals and of sensitization. He emphasized the importance of physical damage to cells as determining a *locus minoris resistentiae*, which not only delayed healing, but also formed a site to which organisms from within or without could gain access, thus nullifying the effects of antiseptics.

Mr. V. ZACHARY COPE said that Lister had claimed to keep operation wounds aseptic by treating with antiseptics everything that came in contact with them. He never claimed to be able to purify by antiseptics wounds which were already septic. Almroth Wright had shown the futility of applying antiseptics to the surface of deeply infected tissues, and of attempts to obtain a direct bactericidal effect by intravenous antiseptics. Flavine was an advance, as it retained its bactericidal activity in the presence of serum, but the problem of dealing with deep infections was still unsolved. Antiseptics were of value where aseptic operative technique was unreliable, and when applied to superficially infected wounds within four hours of infliction.

Sir ARNOLD LAWSON dealt with eye infections, and said that the conjunctiva had a mild self-sterilizing power and partly to the bacteriolytic ferment, lysozyme, and therefore tended to cure themselves. Conjunctival infections assisted by bathing with a bland lotion, while in severe infections powerful antiseptics, especially silver salts, were valuable. Lavage was, however, the important thing in both conjunctivitis and corneal ulceration, and much harm was done by too energetic antiseptic treatment. For prophylaxis—for example, in burns—flavine was ideal, but its lack of penetration restricted its value in active lesions.

Mr. J. S. WOOD (Parkstone) said that different species of animal showed marked differences in susceptibility to infection, in response to antiseptics, and in power of healing. Continental reports were favourable to acriflavine for treating mastitis in cows. He found glycerine unequalled for treatment of wounds. Powdered permanganate diluted with starch powder was valuable for foul, necrotic wounds. He used saline baths extensively for foot wounds in horses.

Dr. L. P. GARROD said that though the therapeutic value of antiseptics was open to argument experimental work had established their prophylactic value in aborting infections in recent wounds. Browning's work was insufficiently known and appreciated. The clinicians' disclaimers based on imperfect technique and partly to the lack of accepted standards for testing antiseptics. There were no generally accepted methods for judging penetrative capacity, power of disinfecting skin, or even killing power in the presence of blood or serum.

STAPHYLOCOCCAL INFECTIONS

Dr. H. J. PARISH (Orpington) read a paper on the specific prevention and treatment of staphylococcal infections. He said that opinion as to the value of staphylococcal vaccines was still divided, and that both Besredka's local immunization by "antivirus" and the use of bacteriophage had been found wanting. This left toxoid and antitoxin for consideration. He discussed the properties of staphylococcal toxin, and said that its haemolytic activity to rabbits' cells was proportional to its dermonecrotic activity and to its lethal effect on laboratory animals. The relation between leucocidins and haemolysins was still uncertain, but the therapeutic and toxic sera in this country contained antileucocidin. Antitoxin could protect animals against many lethal doses of toxin, and gave them some protection against live

Aug. 18, 1934]

THE SECTIONS: SUMMARY OF PROCEEDINGS

virulent cultures. Circulating antitoxin was present in variable amounts in normal human beings, and superficial infections caused little departure from the normal. High titres were recorded in pyaemia and deep-seated infections, and following immunization with toxoid. Several observers had reported good results from toxoid injections in acne, furunculosis, and syphilis; others had been less successful. Some good results were reported with antitoxin in acute infections, but there were many failures. Our attitude, both to toxoid and to antitoxin, should therefore be one of cautious optimism.

Dr. D. S. MURRAY (Richmond, Surrey) had found that toxoid injections usually caused a rise in circulating antitoxin; the optimum effect was probably obtained by the sixth dose. Of his first 100 cases eighty-six showed clinical improvement, and nine out of twelve cases of blepharitis were rapidly cured. Dr. L. P. GARROD had had less encouraging results, and found that a rise in anti-haemolysin titre might occur without clinical improvement. Antibacterial immunity was probably important as well as antitoxic immunity.

SECTION OF RADIOLOGY AND ELECTROTHERAPEUTICS

Friday, July 27th

RADIOLOGY OF STOMACH AND DUODENUM

Under the chairmanship of the President, Dr. J. H. DOUGLAS WEBSTER, Dr. C. COCHRANE SHANKS opened a discussion on the stomach and duodenum after operation.

Dr. Shanks said that radiological examination of the intact stomach was easy, but this was not so after operation, on account of the difficulties in filling the organ, sphincteric control being abolished. He overcame this by using a truss and pad, which was applied to the abdomen and compressed the jejunum. After posterior gastro-jejunostomy there was immediate passage of barium into the jejunum, most of it having left the stomach in seven to thirty minutes. If this did not happen there must be something wrong with the stoma. The complications following posterior gastro-jejunostomy in various loading of the jejunal loop, recurrent ulceration in various situations, jejunitis, narrowing or malposition of the stoma, and duodenal ileus. Dr. Shanks described the x-ray appearances in these conditions, illustrating his remarks by a series of films. After partial gastrectomy by the Billroth II method or the Polya type, recurrent ulcers were less common than after posterior gastro-enterostomy. In cases of carcinoma, the efferent loop, cause obstruction of the whole stoma, the efferent loop, or the afferent loop. Dr. Shanks described the radiological appearances after the various modifications of the Polya operation. Overloading of the afferent limb sometimes occurred in the Polya-Moynihan operation, but never in the Polya-en-Y type. In complete gastrectomy there was sometimes considerable dilatation of the jejunum near the oesophageal stoma simulating the fundus of the normal stomach.

Dr. A. E. PAYNE (Leicester) stressed the importance of noting every feature of preliminary and preoperative radiological examinations in cases of ulcer and carcinoma. Here diagnosis was not enough. The extent, fixation, and outside connexions of such lesions were important because they influenced the desirability of a subsequent operation and its nature. The fluoroscopic methods of "graduated compression and aimed picture-taking" advocated by Gregory, Cole, and Berg had contributed much to the diagnosis of gastric and duodenal lesions. The mucosal rugae had a definite anatomical arrangement, and abnormalities in these folds, combined with the diagnosis more sure than by other methods. It was rarely wise to pronounce an ulcer healed, but the disappearance of the niche and of localized deep tenderness, combined with the disappearance of occult blood from the stools, was fairly reliable evidence of healing. It was the disappearance, and not the absence of tenderness that was important. Mucosal relief methods would not help much in the

diagnosis of new growths. Such cases were almost always so advanced when first seen that they were difficult to miss by ordinary methods. This state of affairs would not be remedied until every patient over 35 with gastric symptoms was thoroughly investigated within a fortnight of their onset. Dr. Payne showed many films to illustrate his paper.

Dr. G. VILVANDRÉ said that melaena was not necessarily the result of recurrent ulcer after gastro-enterostomy. He had had two cases in which diverticulitis was the cause. Indigestion and flatulence were sometimes due to a too high position of the stoma, so that the stomach emptied slowly. Erosion of a jejunal ulcer might give rise to gastro-jejuno-colic fistula, which was shown by the immediate appearance in the colon of barium when the patient swallowed it. Great tenderness over the ulcer was usually a feature of such cases. He had never found it a barium enema was dangerous. He had never found it necessary to use special apparatus for gastric cases. Biloculation of the stomach was usually due to ulcer of the lesser curvature, but adhesions and carcinoma sometimes gave similar x-ray appearances. Diaphragmatic hernia of the stomach could also simulate biloculation. He disagreed with Dr. Payne when he said that gastric ulcers rarely, if ever, became malignant. (Dr. Vilvandré showed films of a case in which this, he thought, had actually occurred.) The use of alkaline powders in patients suffering from gastric symptoms was dangerous in that valuable time was lost if such symptoms were due to carcinoma. Duodenal diverticula, although their discovery was a source of great joy to the radiologist, did not account for the patient's symptoms. Duodenal ulcers could be healed by medical treatment, but he thought that few cases were healed permanently without operation.

Dr. H. W. A. POST, discussing the mucosal technique in the diagnosis of some lesions of the stomach and duodenum, described the anatomy of these organs with particular regard to the mucosal rugae. He said that patients were placed in any desired position for screening. The essentials of the technique were adequate compression and ability to change quickly from fluoroscopy to radiography. The exact stage of a gastric ulcer could be demonstrated, including its depth in the stomach wall and the degree of extension outside it. This technique was also an aid in the diagnosis of malignant ulceration. The diagnosis of gastritis was difficult, and should, he thought, be made with caution. Spasm of the duodenal cap did not necessarily indicate duodenal ulceration, and the latter should not be diagnosed unless seen. Small ulcers of the duodenal cap might not give rise to spasm or deformity. Dr. Post exhibited films illustrative of the mucosal technique.

Dr. G. R. MATHER CORDINER said that demonstration of duodenal ulcer by ordinary methods was often indecisive and always a matter of chance. The classical deformities only existed in advanced and contracting ulcers. He used Berg's "dosed compression" technique which revealed the details of the mucosal relief. Duodenal ulceration could be excluded in the presence of a normal mucosal picture. The ulcer niche—the only sign on which diagnosis was possible—could be consistently demonstrated, usually in two planes—*en face* and *en profile*—and very small ulcers could be demonstrated. He thought it would be agreed that fluoroscopic evidence should be confirmed radiographically, and in this technique films could be exposed at any time during the screen examination by a quick-change device. Ulcer deformity was produced mainly by cellulitis in the adjacent mucosa, and there were many conditions which tended to obscure it. Dr. Cordiner exhibited films illustrating the ulcer niche in the *en face* and *en profile* views.

Dr. G. B. BATTEN asked Dr. Cordiner whether his films were taken in the upright or in the prone position. Dr. CORDINER replied that they were taken in any position which seemed desirable. Dr. A. C. MOONEY (Plymouth) asked Dr. Cordiner what percentage of ulcers with a normal duodenal cap were demonstrated by this method when they could not be shown by any other. Dr. CORDINER replied that the percentage was probably 30 to 40. Dr. VILVANDRÉ said that, although Dr. Cordiner

scoffed at screen examination, most eminent radiologists used it with success. Compression in these cases was not a new technique. It was not enough to demonstrate an ulcer. The radiologist must say whether it was early or late, and what was the condition of the stomach. Cellulitis in connexion with an ulcer was a new term to him. The PRESIDENT said that he was surprised that the use of belladonna had not been mentioned in the discussion. He was convinced of the value of re-examination after its administration. Dr. C. H. C. DALTON (Ipswich) said that duodenal examinations were always difficult, but never more so than in patients who were too well covered. Dr. SHANKS said that he agreed with Dr. Payne that it was the disappearance of tenderness that was the important point as a sign of healing in duodenal ulcer. He did not believe that a barium enema was dangerous in cases of gastro-jejuno-colic fistula. He had never seen perforation occur, although he had seen it happen during ordinary barium meal examinations. He thought that partial gastrectomy was a better operation than gastro-jejunostomy. The mucosal relief technique was interesting, but the results were not yet sure enough to warrant laparotomy on the radiological findings.

SECTION OF TROPICAL DISEASES

Friday, July 27th

TYPHUS IN THE TROPICS

With the President, Professor WARRINGTON YORKE (Liverpool), in the chair, Sir JOHN W. D. MEGAW opened a discussion on typhus fevers in the Tropics. His paper was printed in full in our issue of August 11th (p. 244).

Dr. J. L. GILKS (Petersfield) said that the first description of typhus in East Africa was given by himself in 1920. It was then suggested that the vector was a tick, though it was puzzling that the disease was almost entirely confined to Europeans, only one or two cases having been noted in Indians and only one in an African. Tonking (1932) showed that the typhus of Kenya was a tick, Rickettsia disease, and in 1933 Roberts and Tonking proved that the tick *Rhipicephalus sanguineus* was the transmitter. Europeans only are attacked, owing to the fact that other races are not dog lovers. In Zanzibar and Tanganyika Territory typhus was not a problem, but recent observations in Uganda had shown that there resembled the European variety of the disease, transmitted by lice, but differing from the ordinary epidemic form in its lower mortality and in the low titre of the Weil-Felix reactions.

Dr. WILLIAM FLETCHER described the two forms of typhus met with in the Federated Malay States—rat typhus, associated with urban conditions and transmitted by the rat flea, and a scrub typhus which was transmitted by a mite, *Trombicula*, which inhabited certain species of palm trees. *B. proteus* X 19 was not agglutinated, but the "K" strain was agglutinated in high dilutions.

Dr. A. FELIX dealt with the serological reactions of various types of Rickettsia. There was a complete cross immunity only between Rickettsia containing the X 19 antigen. The importance of agglutinin production in the rabbit was emphasized. The different members of the typhus group fell into the same group, whether classified according to insect vector or agglutinin reaction.

Major G. R. McROBERT, I.M.S. (Burma), said that typhus occurring in the hot season in Iraq and South Persia was more severe clinically than the same disease in cold weather. Variations in climate and race were responsible for wide differences in the virulence of any particular variety of typhus. In treatment it was important to protect patients from heat-stroke, to which they were particularly liable. Intensive hydrotherapy, both internal and external, was of great value, and treatment especially. Adequate sleep was essential, and treatment must not be stopped too soon. Lumbar puncture was useful in cases of severe delirium. After-effects of typhus were frequently unemphasized—they consisted of lack of

concentration, irritability of temper, and defective memory. Major-General D. HARVEY suggested that, though strongly suspected, the transmission of typhus by the tick in India had not yet been definitely proved. Dr. R. C. ROBERTSON (Shanghai) said that in China typhus was apparently of the louse-borne type. Infections due to *Bacillus pyocyaneus*, which was not uncommon in ear infections and in the intestinal tract of Chinese, sometimes gave a false positive Weil-Felix reaction. Dr. C. M. WENYON suggested that larval dog ticks might possibly feed on small rodents such as rats, and thus become infected with Rickettsia, since they also apparently acquired trypanosome infections from rodents. Sir S. RICKARD CHRISTOPHERS, on the other hand, believed that larval dog ticks always fed on dogs. Dr. H. A. YENIKOMSHIAN (Beirut) stated that in Syria epidemic typhus occurred in the winter, sporadic cases occurring in the summer and autumn.

Sir JOHN W. D. MEGAW, in reply, said that though in India there was no laboratory evidence of transmission by the tick, yet the number of cases that had developed typhus after tick bites was too great to be accounted for by pure chance. On the other hand, there was no evidence in India of direct transmission of typhus from man to man, though it was quite possible that other forms of typhus than the tick-borne typhus might occur in India.

SPRUUE

Dr. N. HAMILTON FAIRLEY read a paper on "Sprue and its Modern Treatment." Although the essential cause of sprue was unknown, the syndrome was explicable in terms of malabsorption of fat, glucose, and calcium in the small intestine, and defective gastric secretion implicating the intrinsic factor. The intestinal features were best treated by rest in bed and a graded series of high protein, low carbohydrate, low fat, and adequate vitamin diets: meat or milk protein was equally valuable. The megalocytic anaemia responded specifically to liver extract by mouth in adequate dosage. Parenteral injections of liver extract were less satisfactory. Tetany responded to the high protein diet, especially when reinforced by calcium lactate. Under this regime patients recovered in from six to twelve weeks, and were allowed to return to the Tropics after remaining well with a normal blood picture for six months after ceasing treatment.

Major G. R. McROBERT, I.M.S. (Burma), emphasized the importance of the institution of treatment at the earliest possible moment after the establishment of the diagnosis. Response to high protein and liver therapy was quite satisfactory in the Tropics, and immediate invaliding to Europe was not essential, and in the case of Anglo-Indians impossible. Dr. Q. B. DE FREITAS (British Guiana) stated that he had seen a case of sprue in a negress, while Dr. R. L. SPITTEL (Ceylon) had also seen the disease in natives. He advocated alkaline treatment and frequent colonic irrigation.

SECTION OF ORTHOPAEDICS

Friday, July 27th

ACUTE AND CHRONIC SPRAIN

With Mr. HARRY PLATT, the President, in the chair, a discussion on acute and chronic sprain was opened by Mr. W. ROWLEY BRISTOW.

Mr. Bristow said that in hospital practice, particularly as seen by the medical student, a sprained joint was too often regarded as an uninteresting and unimportant condition. After qualification, however, he found that his reputation as a good doctor would be made, not by his knowledge and management of cerebral tumours, but by his handling of the sprained wrist and the Colles fracture. From every point of view a sprained joint was an important condition worthy of the greatest attention. When a joint was threatened with injury the muscles that controlled it formed the first line of defence. When the strain, and were therefore liable to injury. Partial rupture—the tearing of a few fibres—was far more common

THE SECTIONS: SUMMARY OF PROCEEDINGS

AUG. 18, 1934]

than a complete rupture. Diagnosis presented little difficulty, and it was only necessary to exclude fracture by adequate x-ray examination. Mr. Bristow then considered the general principles governing the treatment of acute and chronic sprain, illustrating his remarks by reference to lesions of the ankle, spine, knee, and shoulder. The breaking down of adhesions was shown to be a relatively simple manoeuvre in the treatment of chronic sprain well within the province of the general practitioner. Unless the profession took steps to practise manipulative methods more widely, patients would continue to go to bone-setters.

Mr. C. GORDON IRWIN (Newcastle-on-Tyne) drew attention to the great importance of sprained backs in the iron workers and pit men. It had been found that thirty-nine out of every 1,000 injuries encountered in the iron trade were sprained backs, and that the average time off work was twelve weeks; in the coal trade the incidence was 70 per 1,000, with an average period of disability of twenty-two weeks. If these cases were not dealt with promptly, permanent disability resulted, and the patient was awarded compensation, which practically amounted to an annuity. He had found that few workers came with an acute back sprain; most of them had already spent a number of weeks in bed hoping for the best. Definite adhesions were present in the erector spinae, which in most cases could be broken down by manipulation without anaesthesia, and the result of such treatment was often a dramatic cure.

Mr. T. P. McMURRAY (Liverpool) pointed out that a sprained ligament usually gave way at one of its bony attachments. An effusion of blood and lymph occurred at the site of rupture, and when healing took place scar tissue formed. The object of treatment was therefore twofold: first, to protect the ligament against strain while healing was in process, and secondly, to ensure that the scar tissue which ultimately formed should not lead to limitation of movement in the joint. The first was best accomplished by protective strapping and the second by encouraging careful movement of the joint at the earliest possible moment. In acute sprain pressure by a pad over the point of rupture did more harm than good; it could only interfere with the local blood supply and so retard the processes of repair.

Sir MORTON SMART reminded the meeting that the inter-spaces between the bones, ligaments, and synovial membrane of a joint were filled with delicate areolar connective tissue which carried the small blood vessels, lymphatics, and nerves supplying the joint. The most trifling sprain invariably injured this areolar tissue. In acute sprain it became infiltrated with blood and lymph, which later underwent organization, with the formation of fibrous tissue. Thus in both acute and chronic sprain the elasticity of the areolar tissue was interfered with, so that the rapid adaptive changes that occurred in it during normal movement of a joint were no longer possible. This was the most prolific cause of persistent discomfort and imperfect function in sprained joints, and was often the result of over-rest. There was no doubt that treatment by rest was dictated chiefly by the presence of pain; but prolonged rest, continued long after the original effusion had taken place, always led to rapid wasting of the muscles. As the circulation in the peri- and intra-articular areolar tissue was largely dependent upon normal activity of the muscles, abolition of movement must inevitably delay the absorption of the effusion into the areolar tissue. He submitted that muscle action, as a means of assisting the natural processes of repair after injury, had not received the attention that it deserved. The benefit derived from the physiological changes resulting from painless muscular action, produced either naturally or by the correct type of electrical stimulation, could not be too strongly stressed. In many cases the patient was quite unable to perform just those movements known to be beneficial, and this was the point at which controlled electrical stimulation was called for. A more radical form of treatment for large joint effusions was described by Mr. ELDON TUCKER. He used a small trocar and cannula to pierce the skin and, after withdrawal of the trocar, passed an aspirating needle through the cannula

into the collection of fluid. In this way it was possible to draw off the blood-stained serum without the slightest risk of introducing organisms from the skin. In some cases of so-called muscle hernia following injury the swelling was really due to intramuscular haemorrhage, giving rise later to an encysted collection of serum which failed to absorb. This condition could often be successfully treated by aspiration. Mr. G. R. GIRDLESTONE (Oxford) was convinced that manipulation was often employed too early in the treatment of chronic sprain. For many weeks after an injury a ruptured ligament was surrounded by young, active, and vascular fibrous tissue. At this stage manipulation could only stimulate this tissue to further activity with the ultimate formation of even more dense adhesions. If a patient with a sprained shoulder of several weeks' duration came for treatment, and marked limitation of movement was found to be present, manipulation under anaesthesia ought not to be performed for at least three months after the original injury. Mr. WHITCHURCH HOWELL recommended traction in acutely sprained joints where a position of flexion was the only one affording the patient any comfort; such a vicious position had to be dealt with promptly to avoid the development of secondary contractures.

SECTION OF DERMATOLOGY

Friday, July 27th

THE TREATMENT OF LUPUS VULGARIS

Dr. RUFERT HALLAM (Sheffield), the President, who was in the chair, opened the meeting with a welcome to Dr. Svend Lomholt, who had come from Copenhagen, and to Dr. Wettenhall of Melbourne. The latter, who is to be a secretary of the meeting of the B.M.A. in Melbourne in 1935, wished him to convey to dermatologists a cordial invitation to Australia. Dr. Wettenhall then himself put forward inducements compensating the time required for the long voyage, which, however, could, if necessary, be satisfactorily done in ten weeks.

Dr. SVEND LOMHOLT opened the discussion on the treatment of lupus vulgaris. This paper is printed in full at page 291 in this week's issue of the *Journal*.

Dr. J. E. M. WIGLEY expressed his admiration for Dr. Lomholt's technique. The administrative routine, and particularly its economic aspect, was a more difficult problem in this country. He agreed with Dr. Lomholt that the efficient treatment of lupus vulgaris could only be carried out on patients who were kept in hospital for at least several weeks. He hoped that the London County Council would see its way to the establishment of a number of light stations in which this specialized therapy, and the equally important general carbon-arc baths, could be given regularly in association with adequate feeding. He urged the importance of school medical officers being familiar with the appearance of lupus nodules, so that cases should come under treatment in the earliest possible stage. He considered erosion of the nodules and packing with powdered potassium permanganate a valuable method in certain cases. He had been using the Finsen-Lomholt lamp at Charing Cross Hospital for four and a half years, with results superior to those he had obtained with the Finsen-Reyn lamp. These results, however, fell a good deal short of those which Dr. Lomholt was able to get in Denmark, and this he ascribed to the administrative difficulties indicated above.

Dr. W. J. O'DONOVAN submitted statistical information showing that of the cases attending the London Hospital as many came from the provinces as from the London area. In order that the administrative questions raised by his friend Dr. Wigley should receive due consideration it was to be remembered that the removal of the London cases would not relieve the clinics of their responsibilities for the provincial ones, nor would it lessen their overhead expenses to set up a new lupus clinic. With lantern slides he demonstrated his belief that ectropion of the lower lids was most commonly the sequel of radium or

THE SECTIONS: SUMMARY OF PROCEEDINGS

[THE BRITISH
MEDICAL JOURNAL]

x-ray therapy, and he stressed the opinion that lupus cancer was known and rare, but that cancer upon lupus after x-ray treatment was not well known, but was far from rare. He mentioned the value of salvarsan and mercury in some cases of lupus affecting the muzzle area. He illustrated the lamentable results of plastic surgery on lupus of the face when not performed by experienced plastic surgeons, and the satisfactory cosmetic effect of painted aluminium noses. His last slide was of a woman, aged 89, with extensive lupus of the face, who had had both legs amputated for tuberculous joints. She had had x-ray carcinoma in the root of her nose, treated by radon. She had been a patient of Koch in Berlin and of Sir Stephen Mackenzie, and, with her lupus still active, had survived two generations of dermatological therapeutic experience.

Dr. WETTENHALL (Melbourne) pointed out the rarity of lupus vulgaris in Australia, and, on the other hand, the frequency of rodent ulcer, both of which facts were attributable to the prevalence of sunlight. Nutrition in Australia was also of a high order, which might account partly for the absence of lupus vulgaris. He agreed that antisyphilitic remedies were often useful in obstinate cases of lupus vulgaris. Dr. H. SEMON advocated the more general use of tuberculin as a supporting treatment among out-patient sufferers. Regarding local applications he wished to draw attention to "pyotropine" (Lupusan Berlin). Its particular attraction was the excellent and cosmetically pleasing scar tissue produced. Dr. J. BEATTY (Cardiff) agreed that pyotropine was a valuable remedy, and mentioned that he had introduced a substitute, details of whose composition he had given in the *Journal* some years ago, because pyotropine was obtained only with difficulty in this country. He was of the opinion that Dr. Lomholt had put the matter too strongly when he said that curettage and cauterization never cured. Dr. NORMAN BURGESS (Bristol) recommended the following substance allied to pyotropine: calcium carbonate, one part; solution of potassium hydroxide, 50 per cent., two parts; and a half parts; ac. carbol. liq., one part. Dr. A. M. H. GRAY was of the opinion that lupus vulgaris predisposed to cancer, even in the absence of x-ray treatment. Where the Finsen-Lomholt treatment was not available he thought it best to give a general anaesthetic, scrape well, and apply potassium permanganate or pyotropine, rather than make repeated applications of a caustic without an anaesthetic.

Dr. LOMHOLT, in reply, agreed that an artificial nose was often preferable to a graft. Tuberculin treatment had been tried extensively at the Finsen Institute, but it had been abandoned. He had seen cases of carcinoma on lupus; in all but one x-ray treatment had been given. Dr. RUPERT HALLAM hoped that the paper which they had just heard from Dr. Lomholt, and the remarks of the other speakers, would have a far-reaching effect. All were agreed that the treatment in this country was lamentably unsatisfactory. In spite of medical inspection of school children few cases presented themselves in an early stage. He was afraid there was little chance of improvement unless the treatment was organized and controlled by some central body. He believed that the Finsen-Lomholt treatment was the treatment of choice. Failing the facilities and funds for this method he advocated a general anaesthetic and scraping with a sharp spoon, followed by the application of powdered potassium permanganate.

FUNGUS INFECTIONS OF THE FEET

Dr. A. M. H. GRAY, opening a discussion on fungus infection of the feet, said that inflammation of the skin might occur in two ways: (1) by the growth of the fungus in the horny layer; and (2) by the transmission of the fungus or its toxins from a local infection to a distant site: reactions of this type were spoken of as dermatophytids. The common types of fungus infection of the feet were: (1) the intertriginous, (2) the vesicular, (3) the hyperkeratotic. In the first type, the most common, the skin between and under the toes was affected; in chronic cases it became thickened into a white layer—

the so-called "soft corn." In more active cases an eczematous eruption spread on to the foot. This might be bullous; secondary infection was not uncommon. In the vesicular form the vesicles were small and deep-seated. Frequently the fungus could not be demonstrated in these cases; some belonged to the group of the dermatophytids. A thickened horny layer, which was very liable to fissuring, was found in the hyperkeratotic variety. Cure was not easy, probably because the hyperkeratosis prevented the penetration of fungicides. Reinfection was very common; this he believed was because the nails were frequently involved. In the acute vesicular types he favoured baths of 1 in 4,000 potassium permanganate. When inflammation had diminished he, personally, strongly recommended Whitfield's ointment. In hyperkeratotic cases 1/4 B dose of x rays was very helpful. Treatment must be continued for some months after apparent cure. The salicylic acid in Whitfield's ointment tended to produce a sodden appearance of the skin; it was his practice on this account to substitute, for alternating periods of a fortnight, boric acid powder for the ointment. Where the nails were found to be involved, they also must be dealt with. Avulsion seemed the only effective procedure. Recurrence might be due to re-infection. When cure was attained all old socks should be destroyed. Shoes should be scrapped if economic conditions permitted. Failing this they should be swabbed out with 2 per cent. formalin. Discussing prophylaxis Dr. Gray said that there were two main methods of prevention of infection: first, by preventing the naked foot from coming into contact with the floor, and, secondly, by using an antiseptic after contact with a possibly infected floor. The use of rubber shoes in swimming baths might well be made compulsory.

Dr. H. CORSI reviewed some aetiological factors underlying Dr. Gray's intertriginous type. It occurred only where skin surfaces were in contact and usually in those whose feet were hot and hyperidrotic and whose footwear did not allow good ventilation of the toes. It was rare, therefore, in women. It was common in well-to-do males, because they wore thick socks and well-fitting shoes of relatively impermeable leather. Young adults of this class spent much of their time at games: hence the term "athlete's foot." With advancing years sweating of the feet was less common, and the disease tended to spontaneous cure. The condition, therefore, was primarily an intertrigo. The fungus had been found in a host of fomites; perhaps it was ubiquitous.

Dr. H. SEMON took a pessimistic view of the possibility of extirpating the disease in the more chronic types of infection. He was gratified to note that Dr. Gray had emphasized the concurrent nail infection. There was no reliable method of dealing with tinea unguium; even avulsion was usually unsuccessful. As regards local disinfection of interdigital spaces he recommended para-nitrophenol applied after decortication treatment with 12 per cent. salicylic acid in spirit. He shared Dr. Corsi's views on the prime necessity of rendering the soil unfavourable to the growth of the fungus, and it seemed rational, if at present unconventional, to urge a more widespread use of the sandal. Dr. M. J. FENTON recommended avulsion of nails under a solution of iodine in alcohol. The vacuum created on raising the nail drew the fluid into the infected parts of the matrix. Dr. J. T. INGRAM (Leeds) suggested that cases fell into two categories: (1) those in which the organism was of prime importance, and (2) those in which the soil was of more importance. The parallel to seborrhoeic infections was close. In the first group simple measures commonly cured the patient with ease. In the latter, when great difficulties were encountered, fractional doses of x rays were of undoubted value. Familial infections were not uncommon. These would be avoided if a child or youth who had tinea cruris also received treatment for tinea of the toes. In schools the associated infection of the toes was commonly overlooked. Dr. J. F. L. WHITTINGDALE (Sherborne) stated that tinea of the toes was a great trouble in schools. General practitioners were not well informed on the subject. Consequently numbers of boys came to school

suffering from so-called eczema of the feet; sometimes even with tinea cruris. He had made it his practice, therefore, to examine all boys at the beginning of each term. Dr. LOMHOLT said the trichophyton test was regularly used at the Finsen Institute. One must remember it was not proof of the mycotic nature of the lesion then present. He had found fungus in the feet of 25 per cent. male and 18 per cent. female students. He recommended treatment with "mycocten," an ester of oxybenzoic acid (Bencard Ltd., London), a substance used also in food preservation.

SECTION OF MEDICAL SOCIOLOGY Friday, July 27th

DEFECTIVE HEARING AS A NATIONAL PROBLEM

With the President (Dr. H. GUY DAIN) in the chair, Dr. G. P. CROWDEN (lecturer in industrial physiology, London School of Hygiene and Tropical Medicine) opened a discussion on defective hearing as a national problem.

Dr. Crowden estimated that there were in this country two and a half million persons suffering from acquired deafness or defective hearing into the causes of rejection years ago, on making inquiries into the causes of rejection of recruits for the Army, he found that the chief single medical cause was old and current middle-ear disease. The causes of acquired deafness were disease, employment, accident, and advancing age, and each presented its own peculiar problems of prevention or correction. He described the use of a gramophone audiometer, developed by the Bell Telephone Research Laboratories in New York, which he had found an ideal instrument for the group testing of children and the detection of early signs of deafness. In a preliminary survey made by this means on elementary school children in Hornsey it was found that 6.6 per cent. of the children had defects in one or both ears, as compared with 0.42 per cent. shown in annual returns for the routine medical inspection of elementary school children. The use of the gramophone audiometer enabled a practical scheme for attacking the problem of defective hearing to be defined, including examination of cases and measurement of defects, medical examination and diagnosis, medical or surgical treatment, retesting of cases, and decision by medical and educational authorities in regard to subsequent care. The experience of the school medical authorities in the borough of Tottenham, where this routine had been followed for the past three years, was most encouraging, for it had proved both possible and practicable, not only successfully to treat a very large proportion of cases of early disease, but to restore hearing to normal in many cases in which the defects were severe.

Dr. A. R. FRIEL, dealing with the problem as seen in a children's clinic, discussed the possibility of reducing the amount of deafness due to diseases of the middle-ear tract. It was nearly always secondary to disease of the nose, throat, or mouth, and it was important to prevent disease by paying attention to the common inflammatory disturbances in these regions. The two common ear diseases found in a clinic were suppurative otitis media and catarrh. When a clinic was newly opened a large number of cases of chronic otorrhoea of a severe type would come forward. In all of these sepsis was at the root of the matter, and in the majority it would be found that the area of sepsis was accessible. For this condition zinc ionization was efficacious. When the area of sepsis was not accessible the patient was sent to hospital for operation. Suppuration and catarrh of the middle ear were both inflammatory in nature, the former being more acute than the latter. When there was a state of acute inflammation rhinitis or tonsillitis would often be found, or, if the child was very young, erupting teeth. In chronic otorrhoea or chronic catarrh of the middle ear, inflammatory conditions of the mouth, nose, or throat would often be found to be absent; they had passed away, but their effects might be lifelong. Recently a method of treatment called "diastolization" had been introduced from Paris, where it was devised by Dr. Gautier. A hollow,

soft rubber bougie, shaped like a comma, was introduced along the floor of the nose between the inferior turbinate and the septum. This acted as a gentle stimulus to the tissues, which stimulus was transmitted to the central nervous system. The vessels contracted, and the glands expressed their secretion. When the bougie was removed the patient, whose nose had been swollen and blocked, was able to blow his nose, and after a few treatments the catarrh disappeared, and the Eustachian tube and nasopharynx were also relieved. Politization was also used to open the Eustachian tube and restore the position of the drum membrane. When tonsils were definitely inflamed and had lost their regular outline they should be removed; he preferred that adenoids be left alone unless they actually obstructed the tubes. In conclusion, Dr. Friel gave some particulars of work at Tottenham, where the medical officer of health, Dr. Kirkhope, had instructed the school nurses to go regularly into the schools and examine the young children to see if they had rhinitis, and send them for treatment whether their ears were affected or not. Children who had been detected in routine testing in the schools or had been tested by the audiometer after coming to the clinic, were examined, treated, and retested. In the report of the medical officer of health for Tottenham, published in 1933, the results of treatment in children over 8 years of age were given. Of 135 ears showing from nine to eighteen units loss, of which ninety-seven showed catarrhal changes and thirty-seven the effects of suppuration, 124 were raised to normal.

Dr. A. H. GALE (Board of Education), speaking of children of school age and adolescents, said that from the educational point of view children with defective hearing might be divided into three groups: (1) totally deaf (outside the range of the present discussion); (2) partially deaf (while not totally deaf, still coming within the definition of Section 69 of the Education Act); and (3) children with defective hearing whose defect was not so severe as to prevent their being educated with hearing children in an ordinary school. It was probable that ascertainment of the total number of the partially deaf might be made more complete by a more vigorous application of ordinary methods. In the third group the medical aspect of the problem was more important than the educational. Nearly all these cases were due to tubotympanic disease. There were two ways in which such children might be found—namely, at routine medical inspection and by routine audiometer testing. Routine medical inspection should include a brief examination with an electric audiometer. Even then cases of early tubotympanic disease might still be overlooked. For the detection of these routine testing with the audiometer was very valuable. All cases of ear disease found at routine inspection or by routine audiometer tests should be examined by an aural surgeon, and before the institution of routine audiometer testing it was essential to see that the provision for skilled treatment was adequate. The ideal solution of the problem lay in the prevention of the disease which caused hearing impairment, but until such prevention was practicable everything possible must be done to detect and treat ear disease in its earliest stages. If the ordinary methods of detecting hearing defects were more thoroughly applied something might be done to decrease the number of those who left school with their hearing permanently injured.

Professor A. W. G. EWING (Manchester) said that, thanks to very elaborate investigations carried out, especially in America by the Bell Telephone Research Laboratories, it was possible now to correlate hearing for pure tone and hearing for speech in a very exact way. In some instances deafness was reported as due to otosclerosis or some form of disease or injury arising after school age, but the evidence showed clearly that deafness originating during school life was a very serious factor. Deafness might not be noticeable by the subject himself, or by his family or teacher, until it seriously diminished his ability to hear speech at conversational loudness. There were many records of children sent to schools for the mentally retarded or defective who proved on further tests to be partially deaf and capable of good progress by

appropriate methods of education. The danger of judging by a very brief test, in which speech sounds or words were used, was that one tended to use very familiar words, and these, as a rule, could be followed under quite severe conditions by a patient with a very considerable degree of deafness. The great developments in the physics of sound of recent years made the time ripe for concerted advance in regard to auditory deafness in which the medical profession and the educational technician could join.

Major-General P. H. HENDERSON (Director of Hygiene, War Office), in giving some account of the problem from the Army point of view, explained that the nomenclature for recording ear troubles of recruits had been changed since 1912 from "deafness" to "diseases of the middle ear," the reason being the deafness was generally merely a symptom of underlying middle-ear disease. In examination of the recruit the drum had to be visualized in every case. Aural examination, therefore, consisted of auriscopic scrutiny and a hearing test. Deafness, from the Army standard, was regarded as inability to hear with either ear, at a distance of 20 feet, a series of numbers including, at random intervals, the figures 66 (high note), 25 (medium note), and 44 (low note), uttered in a strong whisper. The ratio per 1,000 of rejections for deafness or diseases of the middle ear during the decennium 1904-13 was only 3.05, and the ratio per 1,000 discharges on the same account within less than three months' service was 0.42. In the decennium 1924-33 the ratio per 1,000 rejections rose to 45.45, and per 1,000 discharges (now within less than six months', instead of three months', service) to 5.48. Taking the years singly, the ratio of rejections remained fairly constant from 1904 to 1911, but then showed an increase, and an increase was again shown from 1921, when records again became available, to 1928, since which time the figures had remained fairly constant. The cause of this increase was part of a general post-war decline in health and physique among the youths born in or shortly before the period of the war, and the incidence of nearly all the other disabilities which caused rejection had increased in a more or less similar way. He could not accept the view that it was not a real increase, but the result of a stricter and more thorough examination of the ears, the use of electric auriscopes, and so forth. He was forced to the conclusion that the reason for the high incidence of middle-ear disease among recruits was to be found in its prevalence in the young male adolescent population.

Air Commodore A. V. J. RICHARDSON (R.A.F. Medical Service) confined his remarks to the recruitment of aircraft apprentices who were entered at school age for a life career in the technical trades, and to adult recruits, skilled or unskilled, disregarding entrants of the officer class. An analysis of 5,750 candidates medically examined at Halton in half-yearly entries from September, 1928, to January, 1934, showed that only seven per 1,000 were rejected on account of diseases of the ear, including defective hearing; while during the years 1925 to 1932 a total of only five aircraft apprentices were invalided on account of diseases of the ear from an annual strength varying between 1,900 and 1,200. For adult recruits the rejection rate on account of diseases of the ear for the years 1931 and 1932 was eighteen per 1,000 examined, while the invaliding rates for the total force for those years were 0.25 and 0.5 per 1,000. The reason why the Air Force figures were so much lower than those for the Army was probably that the Air Force recruits were drawn from a better class of life and one more likely to take intelligent notice of any disability such as a discharging ear, in its early stages. In the Air Force an endeavour was made, by prompt and energetic treatment, to prevent the acute type of ear trouble from becoming chronic. Such cases were admitted to hospital or kept under the oversight of an expert otologist. Dressings were carried out under aseptic conditions, by sight, and not left to the patient. As to whether work in the Air Force caused deafness, it must be remembered that the personnel were not kept continuously on a particular

type of work; in flying, adequate protection of the ears by properly fitting helmets reduced the damaging effects of noise.

Dr. PHYLLIS KERRIDGE (London School of Hygiene and Tropical Medicine), dealing with the calibration of hearing aids, said that it had long been known that hearing loss was rarely uniform for all pitches. She had recently had the opportunity of examining the graphs of hearing loss with pitch of over 1,000 adults who applied for hearing aids to a commercial firm; 52 per cent. of these persons had maximum loss for high tones, 37.5 per cent. for middle tones, 5.5 per cent. for low tones, and 5 per cent. showed approximately uniform loss. The mean amount of hearing loss of these persons over the range of frequencies most useful for speech was 62.5 decibels—that is, about 50 per cent. of total normal hearing at these frequencies, resulting in an inability to hear loud speech at the ordinary distance, but an ability to hear very loud speech near the ear. The figure worked out the same whether both ears were considered or the data for the better ear only were taken. About three-quarters of the people had losses between 40 and 60 per cent. (50-75 decibels). The above figures might be taken to indicate approximately the amount and character of hearing loss in deaf adults who asked for some compensation. She had obtained similar data on seventy children in a school for the deaf. Prescription of hearing aids had been advocated for some years. The obstacle had been the difficult physical problem of calibrating the hearing aids under conditions comparable to those in which they would be used. It might be said that the physical properties of both horns and microphones were such that the type of deafness with maximum medium tone loss was the most easy to correct at present. Until more data on the magnification of sound by hearing aids over the whole range of audible frequency was available, no rational progress along this line of research could be made. Such calibration involved knowledge and expensive apparatus which neither hospitals nor instrument-making firms had at their disposal. It was satisfactory to know that the National Physical Laboratory was willing to undertake the testing of hearing aids.

Wing Commander STANLEY TURNER mentioned that in 1904 he devised an almost identical apparatus to the audiometer which Dr. Crowden had demonstrated. Dr. H. G. DAIN (from the chair of the Section) said that this was a disability of which the persons who suffered it were not always conscious. The figures which Major-General Henderson had produced suggested that the incidence had gone up far beyond the point at which it could be explained on the ground of improved methods of detection. One manifest duty was to prevent as far as possible the common infections and constant catarrhs.

Dr. CROWDEN, in reply, said that with the audiometer it had been noticed that numbers like three, one, and six tended to be confused in the hearing of some children. In America Dr. Harvey Fletcher, many years ago, showed the link between defective hearing for certain words and vowel sounds and the defects associated with certain high frequencies. Dr. A. F. FRIEL said that diastolization greatly reduced the necessity for the removal of adenoids. In reply to Dr. Ashcroft he added that the rubber bougie was left in position for five minutes.

The Achille Sclavo prize of 10,000 lire, founded by the National Ophthoepathic Institute of Pisa under the patronage of the National Institution for Research, is offered for the best essay on one of the three following subjects: (1) comparative investigations on the total endocrine extracts and their hormones in their physiological and therapeutic aspects; (2) experimental and clinical contributions to the pathology of the thymus; (3) relations between the hypophysis and somatic and metabolic activity. The first prize will consist of 8,000 lire, and there will be two consolation prizes of 1,000 lire each. Two copies of the essay should be sent not later than May, 1936, to the Consiglio Nazionale delle Ricerche, Ministero della Educazione Nazionale, Viale Del Re, Rome.

FACTORIES AND WORKSHOPS REPORT

The report of the Chief Inspector of Factories and Workshops for 1933 devotes short chapters to questions of employment and welfare, but the main portions of the report relate to industrial accidents and diseases. The Chief Inspector (Mr. D. R. Wilson), in his introduction, says that he is chiefly impressed, not so much by the frequency and severity of the industrial accidents incurred, as by the number of them that are avoidable. The contempt for transmission machinery, such as smooth shafting in motion, is responsible for an almost incredible toll of death and disablement, considering that its dangerous character has been continuously emphasized from the very start of factory inspection. Fortunately, safeguards, which make physical injury an impossibility, are now provided for many machines. It is found that particularly dangerous machines such as guillotines for cutting paper sheets and meat-mincing machines can be fully guarded, and steps are being taken, in conjunction with the trade associations, to extend the provision of such guards universally. The use of some of these dangerous machines is not confined to factories, and it was found that of 10,000 butchers' shops visited more than 7,000 failed to comply with the agreed standard of protection in their mincing machines.

ACCIDENT FIGURES

In addition to mechanical safeguards an enormous field is still open in the direction of education, such as is taken by the National Safety First Association. Through the introduction of safety committees at factories, the display of accident posters, and in other ways it has been found possible to reduce the frequency and severity of the accidents incurred in some factories to less than a half in the course of two years.

The improvement in accident rates in most branches of industry has been tested by the Factory Department by tabulating all reported accidents for two sample years, together with information concerning the numbers of workers employed. The data relate to about five million workers in each instance, and it was found that in 1932 the accident rate per 100,000 persons employed was 2,090, as compared with the rate of 2,780 observed in 1928. The fatal accidents decreased in like proportion, so it is evident that the improvement has been very substantial in recent years. The accident rate is naturally much heavier in some industries than in others. For instance, in metal extraction and conversion, shipbuilding, and constructional engineering it is more than ten times greater than in laundries, bakeries, and factories for wearing apparel.

INDUSTRIAL HEALTH

The chapter on health by the Senior Medical Inspector, Dr. J. C. Bridge, gives detailed statistical information about various industrial diseases which should prove of great practical value. For instance, about 150 cases of epitheliomatous ulceration are notified every year, of which about forty are fatal. The majority relate to cotton-mule spinners, but a substantial number occur at patent fuel works, where pitch and tar are the carcinogenic agents. By periodic medical examination of the workers in the fuel industry in one area, and suitable treatment when necessary, fatal results were entirely prevented in the year under consideration. Again, it is found that the workers in certain chemical factories, where intermediate dyestuffs are manufactured, have a mortality rate from cancer of the bladder which is thirty-eight times higher than that of the general insured population of the district. The early stage of the disease is a papilloma of the bladder wall, and if this is removed successfully a complete cure may be looked for.

Silicosis and Asbestosis.—The subjects of silicosis and asbestosis are dealt with at length, and 469 deaths from these causes, or from silicosis combined with tuberculosis, are tabulated. These deaths are a sample collected during the last few years, and do not represent the total deaths incurred, but judging from their number they appear to indicate a greater mortality than that induced by all the other tabulated causes of industrial disease put together

(lead poisoning, anthrax, epitheliomatous ulceration). The fatal termination of silicosis cases ensued on an average after thirty-three years of employment, while that of asbestosis cases ensued after only eleven years. All the asbestosis cases are attributed to exposure prior to the introduction of the Asbestos Industry Regulations, and a great reduction of fatalities may be expected in the future.

The most fatal of all the causes of silicosis is sand-blasting, a method of cleansing or etching surfaces by directing the abrasive on to the article through a nozzle by means of compressed air at a pressure of 30 lb. to 100 lb. per square inch. The operator is protected by a helmet supplied with fresh air, or the process is performed in an enclosed cabinet, but inevitably the air breathed contains an excess of sand particles. Exact information of the number of men engaged in sand-blasting in the Midlands area was obtained, and it was found that of the 441 men concerned no less than 5.4 per cent. died from silicosis in the space of three and a half years. In order to avoid the risk it is suggested that the sand should be replaced by some other abrasive, and it appears that steel grit can be substituted in many instances.

Dermatitis.—Of the non-fatal industrial diseases described dermatitis is responsible for about 1,000 reported cases per year, and it is pointed out that such cases could usually be prevented (a) by placing a protective film of ointment between the skin and the industrial irritants, and (b) by thoroughly washing the skin after work, but without recourse to cleansers (except in the case of contamination with oil). The workers' hands ought to be regularly inspected, so as to detect early signs of skin irritation.

CONDITIONS OF EMPLOYMENT

In the chapter concerned with employment it is pointed out that the recrudescence of industrial activity is, unfortunately, accompanied by an increase of illegal employment. In a number of cases young persons have been compelled to work disgracefully long hours. A boy in a dry-cleaning works was employed 156½ hours in eleven days, including spells of work of twenty-two and a half and thirty-seven and a half hours. Girls of 14 and 15 were employed from 8 a.m. to 12.30 p.m., and then during the night (when such work is absolutely forbidden by law) from 6 p.m. or 7 p.m. until 3 p.m. on the following afternoon. Needless to say, the employers were prosecuted and substantial fines inflicted.

As regards shift work, the two-shift system of employment is being used to an increasing extent, and 318 fresh Orders were made by the Home Secretary in 1933. These Orders covered a very wide range of industries, and they are likely to be extended greatly in the future, as they enable the employer to keep his plant running for eighty-two hours a week instead of the usual forty-eight hours. The overhead costs are so much reduced that it is possible to pay the workers as much for the shorter working week as for the longer one, and it is found that the majority of them, once they have settled down to the change of habits involved, prefer the system because of the gain in leisure.

It will be realized that this brief summary necessarily omits any reference to most of the vast body of inspections and other work carried on by the staff of 240 inspectors attached to the Department. The number of factories and workshops subject to inspection was no less than 285,284, and it is astonishing that so limited a staff are able to accomplish their work so efficiently.

The Association d'Enseignement Médical des Hôpitaux de Paris announces the programme of its course in cardiology, which will be held at the Hôpital Broussais from October 8th to October 20th, 1934. This particular course deals with the arrhythmias, and is directed by Dr. Ch. Laubry, with the assistance of Professor Doumer and Drs. Marchal, van Bogaert, and Aitoff. The fee is 150 francs. A time-table is issued covering the whole two weeks. Facilities are given for examination of cases daily at 4 p.m., and students may obtain a diploma at the end of the course. Further particulars may be had from Dr. Lemant, Hôpital Broussais, 96 rue Didot, Paris (14).

England and Wales

The L.C.C. Medical Staff

The establishment of medical staff at general hospitals under the management of the London County Council was fixed in January, 1932, but it is now found that developments have rendered an increase necessary. The type of case treated in the general hospitals is altering, and there is continually more acute and operative work to be carried out. The general standard of medical care, moreover, is steadily rising. The improved facilities for pathological work created by the new laboratory services encourage the more elaborate investigations required by modern hospital methods, and thus there is an increased demand on the time of the medical officers. The wider and freer use of consultants under the recently organized consultant and specialist scheme has had the effect of raising the standard of treatment and increasing the amount of care and time devoted to the cases. Further demands on the staff have resulted from the developments in out-patient work, as, for example, in the ante-natal and post-natal clinics and in diabetic and other special clinics. A careful survey has therefore been made of each hospital, and at the last meeting of the Council before the summer recess the Hospitals and Medical Services Committee brought forward proposals for an increase, as from October 1st, of the fixed establishment of medical staff by four positions of senior assistant medical officer (from thirty to thirty-four), twenty of assistant medical officer (from twenty-five to forty-five), and seven of house-physician, house-surgeon, or clinical assistant (from twelve to nineteen). Proposals for additional medical staff at Hammersmith Hospital have not yet been made, but it is stated that there is no doubt when the works of adaptation and enlargement at that hospital are completed, and the post-graduate medical school is opened, the medical staff will have to be strengthened. The medical staff employed at special hospitals was fixed in July, 1932, but here also it has been found that the number of permanent staff available cannot be considered adequate during periods of high incidence of various diseases, and it has been found impracticable during these periods to avoid having a higher proportion of temporary staff on duty than should be the case. At Colindale Hospital and King George V and Pinewood Sanatoria, where cases of pulmonary tuberculosis are treated, the staff has proved inadequate. The treatment of tuberculosis, it is pointed out, has undergone very great changes. The various forms of collapse therapy and chemotherapy, the greatly increased use of radiological examination and blood examinations in guiding treatment and estimating prognosis have made treatment more individual and intensive. The work of the medical staffs has been thereby increased to an extent which now throws an undue strain upon the medical officers concerned. It is proposed to increase the fixed staff at special hospitals by two positions of senior assistant medical officer (from twenty-one to twenty-three), and by making five new positions of assistant medical officer. The appointments of assistant medical officers (Grade II) are limited to one year only, in accordance with the recommendation of the Askwith Conference. This limitation has been found unsatisfactory to the Council and to the officers themselves, and it is proposed to renew their appointments for a second year, endeavouring to ensure that a large proportion of the second year shall be spent in another hospital, or that the officer's duties are varied if he is to be retained at the same hospital. It also appears that the Council's stipends do not attract, at the existing salaries, the type of medical officer for which the positions of house-

physician, house-surgeon, and clinical assistant are intended. These positions are to be maintained, but the rates of pay, which are £80 a year, with residential emoluments, for house-physicians and house-surgeons, and £100 a year, with meals on duty, for clinical assistants, are to be raised to £120 and £150 a year respectively. The financial effect of these proposals for increase of staff and of certain salaries will be £5,345 for the current financial year and £10,810 for 1935-6.

Radiotherapy at University College Hospital

A new appointment was made in 1933 in the radiotherapy department at University College Hospital, an assistant radium registrar being entrusted with the superintendence of the working of the 1-gram radium unit. Four beds in the surgical wards—two for male and two for female patients—have been set aside for those undergoing this form of treatment, which is now in almost continuous operation during the night as well as the day. Previously time was lost in transferring the bomb from ward to ward, and the number of those skilled in its use was limited. Each exposure lasts about two hours, and most patients tolerate this without great discomfort. When the treatment was given in bed constant supervision was required, since the patient tended to move and the alignment had often to be altered. The couch now employed is fitted with an adjustable head-clamp, and, if the patient is arranged comfortably at the beginning of treatment, he is relieved of the strain of voluntarily maintaining his position relative to the bomb. In the report of the work of this department for 1933 it is stated that the calculation of dosage of radium administration remains largely empirical, but the recent increase of dose has improved the immediate results. At present sixteen to eighteen hours' intermittent exposure is given to each field where two or three adjacent fields are employed, and twelve to fourteen hours each to four or more fields. An average dose for one side of the neck or one groin is fifty hours, or 100 hours to both sides. With this increased dosage a fairly severe skin reaction is generally produced, and moist desquamation occurs about two weeks after the cessation of treatment. The skin heals readily if protected with a greasy application. There is rarely any marked constitutional reaction. Of fifty cases treated with this 1-gram unit since August, 1932, twenty are recorded as improved, eight as not improved, and thirty-one as dead. In the period 1921-32 radium treatment for malignant disease was used in 937 cases. Of these patients 321 are still alive, ninety-six having survived for five years or more after treatment, and 225 for less than five years. A change has also been made in the distribution of the radium stock, an 11-mg. needle on loan from the Medical Research Council having been converted into the more useful form of ten small needles. To maintain the constant control of x-ray dosage the physicist has continued to standardize weekly the intensity output of the deep-therapy tube. The American deep-therapy Coolidge tube in Dean's twin coil unit was used only for a few hours, the stabilivolt unit being found to be both safer and quicker. The Siemens water-cooled tube worked 1,163 hours in 1933. The total working hours of this tube are now 2,056, which is considered to be highly satisfactory. In comparison, the lives of three air-cooled tubes used in 1931 totalled only 227 hours. A filter of 0.5 mm. of copper and 1 mm. of aluminium was employed with a kilovoltage of 150. The copper filter was doubled when the kilovoltage was raised to 190. An even darker erythema was taken as a standard for the U.S.D. With a kilovoltage of 190 and a filter of 1 mm. of copper and 1 mm. of aluminium this was found to be 1,000 international r units when esti-

ENGLAND AND WALES

AUG. 18, 1934]

mated with back-scatter. The intensive split dose method was used for nearly all malignant cases, the fractional dose method being confined to non-malignant conditions. The duration of treatment in the former ranged from one to five weeks. The single, or massive, dose was only used for carcinoma of the skin. In the arrangement of the statistical side of this annual report that of the summary of reports issued by the Medical Research Council is followed. The diseases treated are classified in fourteen groups, while a further subdivision of the sarcomata has been added. The new patients during the year totalled 321, 226 of whom had malignant disease. Of the malignant cases eighty-seven were treated with radium, seventy-four with x rays, fifty-eight with radium and x rays, and seven with x rays after treatment with radium elsewhere. Of the ninety-five non-malignant cases fifty-five were treated with radium and forty with x rays. The old patients at the commencement of the year numbered 103, of whom seventy-seven had malignant disease. Radium treatment was given to thirty-six of these malignant cases, x rays to thirty-three, radium and x rays to seven, and x rays to one who had had radium treatment elsewhere. Of the twenty-six old patients with non-malignant disease eight were treated with radium and eighteen with x rays.

Pathological Research in Leeds

The annual report for 1933 of the department of pathology and bacteriology of the University of Leeds has been compiled by Professors Matthew Stewart and J. W. McLeod, and is published with an abstract of a report on experimental pathology and cancer research drawn up by Professor R. D. Passey. There has been a large increase in the general routine work, chiefly in connexion with the General Infirmary, and of a bacteriological kind. No fewer than 30,000 examinations were made in the department, an increase of 2,000 over the previous maximum in 1931. On the research side, a report on the pulmonary fibrosis of haematite miners has been prepared and presented to the Industrial Pulmonary Disease Committee of the Medical Research Council. The sputum of asbestos workers is being examined as opportunity serves, and a growing body of evidence points to the presence of clumps of asbestos bodies as an important indication of a destructive lesion of the lung, and, *ipso facto*, of pulmonary asbestosis. A suitable procedure for urea-clearance determinations and their application to the investigation of renal disease has been devised, and is now in routine use in the General Infirmary at Leeds. It is believed that this offers the best available method of ascertaining the state of renal function. Some success has been forthcoming as regards the devising of a method of determination of the "non-haemoglobinous" iron of blood on the basis of the technique already in use for estimating the amount of iron in the blood, tissues, and urine. This technique has been adapted for use with haemoglobin-free blood plasma, and it is believed that it will soon be available for determination of the iron content of the blood plasma in the study of the various forms of anaemia. Two types of lesion of the epithelium of the cervical canal have been singled out for special study as being possible precursors of carcinoma—namely, leucoplakia of the portio vaginalis and squamous metaplasia of the cervical canal epithelium. The glycine-tolerance test for liver damage has been modified and applied to the human subject. It has been shown that the subcutaneous administration of 1 gram of glycine is innocuous, and capable of indicating sometimes the existence of hepatic disease. The use of higher doses is likely to prove more reliable, and is being investigated. The attempt to correlate bacterial type with clinical severity in diphtheria

has now been in progress for more than three years. The observations indicate that the *B. diphtheriae gravis* type is associated with severe diphtheria in all places where it predominates; it is the most constantly animal-pathogenic of all forms, and has been found to be definitely predominant in all definitely endemic diphtheria areas. The intermediate type of bacillus has been shown to be the predominant strain in both severe and mild diphtheria, but not to be associated with marked epidemics. The *mitis* form has only rarely been found associated with severe toxic diphtheria, the majority of fatal cases in which it was present having been complicated by obstructive lesions or bronchopneumonia. A wider fluctuation in animal pathogenicity was detected among *mitis* strains than among those of any other types.

Liverpool Psychiatric Clinic

The Liverpool Psychiatric Clinic was founded in April, 1924, in two rooms in a dwelling-house, and a review of the work accomplished in the last ten years has now been issued. In all 1,348 cases have been investigated, the number of patients' attendances being 13,728. After the first three years the clinic was removed to an entertaining hall, and in 1929 the present more commodious premises were obtained. While active psychological treatment was its primary aim, its functions had soon to be extended to include diagnosis and advice in the treatment of cases of advanced mental disorder and functional disturbances. The clinic only receives patients from medical practitioners or some responsible social organization after the presence of physical disorders has been excluded; the patient remains under his care or in that of a hospital while any such disorders are in need of treatment. In this way is preserved continuity of treatment on a team basis without the need for dispensary or laboratory departments. The clinic undertakes the preparation of detailed reports upon cases of delinquency and the investigation of problems peculiar to childhood. There has been a steady increase in the proportion of adolescent cases, indicating a growing tendency for patients to be sent for investigation at a relatively early stage in their neuroses, and at a time when the duration of treatment can often be shortened. Thus, in the first 1,200 consecutive cases, 114 out of 548 males and 175 out of 652 females were between the ages of 10 and 19. During the past twelve months lectures have been delivered to outside course of lecture—the medical staff, and an official course of lectures for social workers and other trained observers was held at the clinic during April and May of this year. The medical staff is entirely honorary, but it is hoped to engage upon a remuneration basis the part-time services of junior medical graduates who have undertaken to specialize in this work.

Mental Disease Research in Birmingham

In a prefatory letter to the annual report for 1933-4 of the Joint Board of Research for Mental Disease of the City and University of Birmingham the chairman, Sir Gilbert Barling, announces that there is a good prospect that the University will be able to provide accommodation for the research work of the Board in the new buildings when the medical school is established at Edgbaston. He also states that, in order to promote interest in the pathology of mental disease, there has been brought into being a new organization—the Midland Mental Pathological Society—to which it is hoped to attract especially the medical officers of the local mental hospitals, and by which should be advanced the projected formation of a strong board of research for the Midland area. The director of the

Board, Dr. F. A. Pickworth, reports that researches have been continued into the blood supply of the brain in mental patients, and that over 330 photographic records have been prepared of sections of brain stained to show the distribution of the capillaries. In continuation of the Board's work on nasal sinus infections residua of past infective processes were found in 54 per cent. of post-mortem examinations; in twenty out of fifty-nine cases actual pus was present in one or more of the sinuses. *Streptococci*, *B. coli*, and the influenza bacillus were the organisms most commonly recovered. Agglutination investigations disclosed responses to Aerttrycke and Gaertner infection in no fewer than ninety specimens; these represented seventy of 656 new cases (10.7 per cent.). This evidence of previous infection (mostly without clinical symptoms of enteritis) with organisms of the food-poisoning group in mental patients is considered especially important in view of the information published already by the Board with regard to the diminution in the oxygen capacity of the blood in Gaertner infections. A roughly quantitative method for the detection of minute amounts of blood in serum has been developed, and applied to the determination of haemoglobin in sera sent for routine Wassermann testing. Graphs constructed of the incidence of blood in the specimens obtained from Wassermann positive and negative sera showed no significant difference. The same test applied to the detection of corpuscular haemolysis by cultures has rendered it possible to isolate a number of haemolytic streptococci and staphylococci.

Scotland

Eradication of Bovine Tuberculosis

At the annual congress of the National Veterinary Medical Association of Great Britain and Ireland, which was held in the Royal (Dick) Veterinary College, Edinburgh, during the week following July 30th, several subjects bearing upon human medicine and public health were discussed. Major A. Douglas, M.R.C.V.S., Ayr, opening a discussion upon the eradication of bovine tuberculosis, said that free tuberculin testing and advice, together with a small premium on Grade A (T.T.) milk, would give the best results within the next few years. The report of the Cattle Diseases Committee had suggested that as an inducement to owners a higher price should be guaranteed for the tubercle-free cow, and that loans should be given to farmers towards the purchase of animals to replace those showing a positive tuberculin reaction. Mr. G. P. Male, Reading, said that the present policy aimed at the total eradication of bovine tuberculosis, at first by voluntary methods of free testing, advice, and bonus to induce producers to clear their herds; but in five years' time the local authorities should be given powers to pasteurize all milk except that coming into their areas from tubercle-free herds. In the meantime it was proposed that routine clinical inspection of dairy herds should be made compulsory. Dr. W. A. Lethem of the Ministry of Health drew attention to the financial benefit that would accrue to farmers if public confidence in milk was established and the demand for it increased. Great Britain was at present the second lowest milk-consuming country in Europe, and the medical profession could not conscientiously recommend the public to drink more milk, because ordinary milk, on an average of 5 to 10 per cent. of samples, contained living tubercle bacilli. The establishment of confidence would depend largely on the work of the veterinary profession, and then the demand for milk would increase and the farmer would benefit. Sir W. Dalrymple-Champneys, Senior Medical Officer to the Ministry of Health, said that the

veterinary practitioner must be the spear-head of the attack on bovine tuberculosis, and that pasteurization and eradication should go hand in hand. Mr. William Nairn, M.R.C.V.S., referring in his presidential address to the Milk Marketing Scheme, said that the interests of the consumer, as well as those of the producer, must be kept in mind; if the veterinary profession were successful in rendering milk free from infection, the producer would then be able to offer a safe milk at a cheap price. It was hoped that in dairying districts the payment of a bonus for tubercle-free milk would stimulate this movement. Various other subjects, such as the application of biochemistry to veterinary practice, the causes of mortality among calves, and the toxin of grass sickness, were also discussed by the congress.

Royal College of Physicians' Laboratory, Edinburgh

The annual report of the Laboratory of the Royal College of Physicians at Edinburgh for 1933 shows that there has been considerable development of relations on the research side of this laboratory with the Department of Health for Scotland, the Home Office, and the Health Section of the League of Nations. Research has been carried out in vital statistics and epidemiology, in industrial diseases, bacteriology, histopathology, chemotherapy, and carbohydrate metabolism. Twelve papers have been published from the laboratory during the year, and five more are in the press. Research has been conducted by eighteen workers upon twenty-two different subjects. In the reporting department 14,203 reports have been issued as compared with 13,988 in the previous year.

Public Health in Aberdeen

In his annual report for 1933 on the health and sanitary conditions of the county of Aberdeen, Dr. H. J. Rae, county medical officer of health, refers to a recent co-ordination of medical services which comprised: amalgamation of the county bacteriological services with those controlled by the Aberdeen Town Council; co-ordination of the veterinary services of the county and the town; and internal reorganization of the sanitary department, whereby the county has been divided into four sectors—similar to those of the Roads Department—each having a divisional sanitary inspector and an assistant. In 1932 there was a concentration of the institutional accommodation for infectious diseases, the number of hospitals being reduced from twelve to five. No inconvenience resulted, despite an abnormally high incidence of scarlet fever in the second half of the year under review. None of the abandoned institutions has yet been reopened for other purposes, but it is hoped that one or more may be found useful when it becomes possible to segregate more efficiently such different classes of the community as able-bodied poor persons, the sick, maternity cases, mental defectives, and lunatics, which are at present being dealt with collectively in public assistance institutions. The respective councils of Aberdeen county and town agreed in 1930 on a scheme of co-ordination, the county council of Kincardine being admitted, at any rate for the present, on a customer basis. The medical and lay team work which has resulted therefrom during the last three years has conduced to economy in time and money, as well as definitely increasing efficiency. Difficult cases which could not be properly treated in the county council's own hospitals are transferred to those of the town council, where specialist services in every branch of medicine and surgery are available. The transference of patients to central institutions is now rendered easy and safe by modern methods of transport. The scarlet fever outbreak was conveyed usually by direct contact, but the milk supplies were involved in some instances. Notification

AUG. 18, 1934]

CORRESPONDENCE

AUG. 18, 1934]

of cases and correlation of the milk suppliers concerned resulted on one of these occasions in the detection of a milker who was a carrier; the epidemic ceased at once when he ceased this occupation. Dr. Rae remarks that stoppage of the milk in such cases is never practised, the usual efficient method being immediately to change the milkers, and to retain the substitutes until such time as the previous ones can be certified free from infection. He adds that this increase in scarlet fever notifications during the latter half of last year, which was general throughout Scotland, was associated with an exceptionally fine summer, indicating that good weather and freedom from the ordinary infections do not necessarily go hand in hand. While ample evidence was obtained of the value of Schick-testing and of injections of toxoid-antitoxin mixture as a preventive of diphtheria, the efficacy of the similar scarlet fever prophylaxis was found to be more debatable. Dr. Rae thinks that it would ultimately be an economic proposition to have a small temporary

NDENCE

medical staff to Schick-test school children, and to immunize the susceptibles and the children of the pre-school age period. It is claimed that the Aberdeen Council has availed itself more than most local authorities of the advantageous provisions of the Housing (Rural Workers) Acts of 1926 and 1931. A progressive housing policy has been adopted, but new houses are only provided where there are adequate water supplies and drainage facilities. Through a judicious decanting process few cases have been encountered where real difficulty has been experienced in meeting increased rentals. Financial considerations have limited activities mainly to reconditioning or demolishing unfit properties, and the problem of overcrowding has hardly yet been tackled, but a survey is being made of overcrowded houses in the villages and hamlets. It is considered useless to make a survey of overcrowding in cottar houses, since many farm servants, irrespective of the size of their families, form a floating population.

Sodium Evipan Anaesthesia

Sodium Evipan Anaesthesia

SIR,—I have read with great interest the paper by Dr G. Slot and Mr. A. H. Galley in your issue of August 4th (p. 201) dealing with sodium evipan anaesthesia. There is one point, however, upon which I should like to join issue with the writers. This is with regard to its margin of safety, which they maintain is a wide one. I have now administered evipan on about seventy occasions, and this short series has taught me that, although undoubtedly of great usefulness in selected cases, it should not be regarded as a routine substitute for gas or gas-oxygen for operations of short duration. The comfort and ease of induction appeal most strongly to certain patients, and I foresee a very real danger of their demanding evipan and I foresee a very real danger of their demanding evipan narcosis for operations such as simple dental extractions, where nitrous oxide administered by the nasal route would be the anaesthetic of choice. After all, the mortality from gas is negligible, whereas that attributable to evipan already assumes rather alarming proportions. To this list I intend to add yet one more.

An elderly man, complaining of dysphagia, was admitted to the Royal Surrey County Hospital for an oesophagoscopy. He was in a very frail and cachectic condition, and had been unable to swallow fluids for some days. Five c.c.m. of a 10 per cent. solution of evipan were injected into a vein, and at once his pulse became thready and finally unperceptible. In spite of artificial respiration and the usual resuscitative measures he died. Post mortem his stomach was found to be solid with carcinoma, which involved the cardiac orifice.

Admittedly this was an extremely bad risk, but I have had two other cases which caused me much alarm on account of their pulse irregularity and deep anaesthesia with small doses. Conversely, there have been two patients in my series who were almost completely unconscious after the injection of 10 and 15 c.cm. respectively. One of these was for diathermy of the tongue, rendering the subsequent use of ether impossible, and as chloroform is contraindicated with evipan the operation had to be postponed. Three days later it was performed comfortably under gas-oxygen anaesthesia with a little chloroform, given by the endotracheal route.

Dr. Slot and Mr. Galley do not state in their paper on how many occasions they have administered evipan. But it is a drug of fairly recent introduction, and their series cannot total many thousands. Nevertheless they report six cases of respiratory failure or spasm (one patient

died); three cases of complete failure of anaesthesia; two cases of inflammation at the site of injection (one leading to abscess formation); and several cases of muscular twitchings, headaches, emotional crises, etc. Surely such findings must strengthen the opinion that sodium evipan should be used in selected cases only and with great caution, and, above all, must not be regarded as a substitute for nitrous oxide or ethyl chloride, the safety and convenience of which have been proved in thousands of operations.—I am, etc.,

A. BARNESLEY.

Thrombosis of the Penis

Thrombosis of the Penis

SIR,—In his paper in the *Journal* of August 11th (p. 249) Mr. Clifford Morson writes: "There are three diseases which may lead to clotting of the blood in the cavernous spaces. They are malignant disease of the left kidney, lymphatic leukaemia, and arteriosclerosis."

Personally, I can remember having seen only two leukaemic patients who had, or had had, "persistent priapism," and both of them were examples of undoubted myeloid, not lymphatic, leukaemia.

One of these patients was a boy, aged 11 years, demonstrated by Dr. Pearse Williams at the Royal Society of Medicine (Section for Study of Disease in Children) on April 25th, 1924 (*Proceedings*, xvii, 55). The spleen was greatly enlarged, and of the 643,000 leucocytes (per c.mm. of blood) 18 per cent. were myelocytes. The other patient I saw many years ago with the late Mr. E. Michels, F.R.C.S. He had typical myeloid leukaemia, and during the year preceding one in which I saw him he had suffered from "persistent priapism" for eighteen days—until a surgeon incised the penis. I referred to this latter case in a discussion (*Proceedings*, Royal Society of Medicine, Section of Medicine, 1912, v, 105).

I have not had time to look up references to recorded cases of persistent priapism in leukaemia, excepting that of E. C. Hadley (*Clinical Journal*, 1915, xlv, 141), in a miner aged 27, and that of H. O. Ruh (abstract in *Lancet*, 1913, i, 843) in a painter aged 36, both of these were examples of myeloid leukaemia. Mr. Morson would apparently prefer to term all such cases "pseudo-priapism," but I can see no reason (compare, for instance, definition in the New Sydenham Society's *Lexicon*) why they should not be still classed under "persistent priapism" (due to thrombosis.—I am, etc.,

London, W 1, Aug 17th

F. PARKES WEBER.

Asthma in Children

SIR,—In support of Sir James Dundas-Grant's moderate view of the importance of attention to the nose in asthma (*Journal*, August 4th, p. 231), two cases which have come under my care during the last month are good illustrations. As it happens, both are from London, and have been seen by specialists there and elsewhere.

The first, a young man of 26, asthmatic from childhood and with "pigeon" chest, has consulted about a dozen doctors, who missed the important facts that his right antrum was full of curdy pus and his septum so badly deviated as to cause mouth-breathing. The sinusitis has probably lasted from childhood. All treatment was hopeless without attention to these, especially to the sinusitis, which, however, was promoted by the septal obstruction. He is already much better.

The second case is a lady of 53. Her nose is normal and needs no attention. But she wears dentures, and has only three of her own teeth, grossly septic. Despite this she had been given as major treatment a vaccine prepared from her sputum—a comparatively useless measure in most cases, and certainly in this one until the teeth are extracted.

The lesson is that the nose should be examined in all asthmatics. In asthmatic children it rarely needs direct treatment, as they mostly become perfectly well with simple detoxicating measures and attention to hygiene, including diet—and this no matter what the history is as to allergy and heredity. If, however, they are mouth-breathers, this ought to claim early attention—usually for tonsils and adenoids—for asthmatic mouth-breathers are apt to be difficult to cure—further evidence of the importance of the nose in asthma.

The fact that asthma in animals—cats, dogs, horses, and canaries—yields to hygienic treatment without attention to the nose supports the view of those who hold that nasal treatment is often overdone. My latest case of this sort was a badly asthmatic dog—harsh pelt, spasms of cough, and dyspnoea when it attempted to walk across the floor, and 20 per cent. eosinophils in blood. In a month it was, as its owner said, "another dog," with glossy coat, lively, and free from respiratory trouble: eosinophils 4 per cent. The treatment was the same as for children—diet, mercurials, iodide, and belladonna.

Those who overemphasize heredity and allergy as important factors in asthma will find food for reflection in such cases in animals. On the other hand, those who minimize the nasal factor will find sane and penetrating statements on the subject in the writings of Sercey of Zagreb and of Hofbauer of Vienna. Finally, those who decry the toxic factor will be surprised at the dramatic results sometimes obtained in severe and constant asthma from the colonic douche as advocated by Dr. A. J. D. Cameron—a measure, of course, not needed for children.—I am, etc.,

Glasgow, Aug. 6th.

JAMES ADAM.

Increased Mortality from Diabetes

SIR,—I am much interested in the questions raised under the above heading in the *Journal* of July 28th and August 4th, especially as I was on the point of writing to the *Journal* commenting on the very noticeable increase in cases of this disease coming under my own observation.

Within the last few years, in a small scattered community, eight cases (excluding a young woman of 23 who died three years ago) have been diagnosed, only one of these being under 40 years of age. The oldest patient is 65. The cases are equally divided as to sex. So used have people become to what was hitherto very rare that the layman gossips casually of how many units of insulin So-and-so requires daily as compared with Mrs. X. The

patients' occupations are as follows: ex-service man 1, indoor worker 1 (aged 29), ex-hotel worker and farmer 1, estate worker 1, and housewives 4. All save two are on insulin; the remainder maintain fair health on diet. In striving to find a common factor in the lives of these people one characteristic stands out—they are all possessed of unusual energy, quick, restless, nervous people who are always doing things. They are not exposed to any undue strains, and there is certainly sufficient quiet and absence of rush in their surroundings. The women all have grown-up families (from one to four in number). None of them (the women) smoke, nor have they been excessively keen on sweetstuff.

Some time ago I read of an American surgeon who had derived excellent results in diabetes by damping down the action of the adrenals and pituitary body by means of x rays. It seems to me a fairly reasonable explanation that there is an increased hormonal excitability—of the adrenals particularly—which manifests itself in the restless energy of these cases, and that this excessive secretion swamps and exhausts the pancreas. Why this should occur is, of course, the problem. Exhaustion and strain are so much the portion of many people that there must be some other factor, probably toxic in origin, awaiting discovery. One world-wide toxin we do have in the epidemics of influenza which visit us in varying forms but with unflinching regularity every spring. It penetrates to the most remote hamlet, and the great majority succumb at some time or another. It is quite possible that these recurrent illnesses in susceptible individuals may exercise a selective toxic effect on the pancreatic island tissue.

I feel that there is a long slow mounting of the pathological condition which ends in the diabetic state, and that if we could recognize this in time the disease itself might be averted. There is always a vague history of long-standing absence of well-being, sometimes of some years' duration, not sufficient in itself to cause the patients to seek medical advice until the onset of the graver and characteristic symptoms. I await with great interest further observation and discussion on this subject.—I am, etc.,

FLORA L. MACDONALD, M.B., Ch.B.

Aros, Isle of Mull, Aug. 6th.

Injection Treatment of Complete Rectal Prolapse

SIR,—I should like to support Mr. Arthur S. Morley in his plea for a wider recognition of the method of treating prolapse of the rectum by injection (*Journal*, August 4th, p. 204). I would also recommend that its efficacy be invariably tested before resort is had to more serious operative procedures. I first learned of the method in 1919, from the late Professor D'Espine of Geneva, where it had evidently been in common use for many years. Since then I have had the opportunity of treating many cases in childhood, and comparatively seldom have I known it to fail. Although the principles of the operation employed by Mr. Morley and that recommended by Professor D'Espine are the same—namely, the introduction of an irritant into the perirectal tissues, so that adhesions are set up with an anchoring of the bowel—the nature of the fluid introduced and the route of injection are different. Mr. Morley employs carbolic acid in almond oil, and apparently injects through the rectal mucosa. Professor D'Espine recommended absolute alcohol, and injected it into the perirectal tissues via the perineum.

I have previously published the technique employed and the results obtained (*Brit. Journ. Child. Dis.*, 1921, xviii, 83; *Lancet*, 1923, i, 76; *The Clinical Study and Treatment of Sick Children*, 1934, p. 141). The following is a description of the operation from the last source.

"In order to avoid all straining the operation must be performed under full anaesthesia, and it is advisable to empty the lower bowel by means of an enema. The prolapse, if down, is reduced and the perineum washed and sterilized with iodine. With the finger in the rectum to act as a guide, 1.5 c.cm. of absolute alcohol are then introduced on each side into the perirectal tissues at a depth of two to two and a half inches. An ordinary exploring syringe is employed, the needle being inserted on each side about a quarter of an inch from the anal margin. The needle punctures are sealed with collodion, a pad placed in the perineum and kept in position by strapping the buttocks firmly together. Instructions are given that the child must move the bowels only while in the recumbent position, the faecal matter escaping by the side of the dressing. The pad and strapping are reapplied daily for a week; by this time it has been found, as a rule, quite safe to discard all appliances. Occasionally the operation has to be repeated once, or it may be twice. There would seem to be no danger with this procedure, as untoward after-effects have never been observed."

—I am, etc.,

London, W.1, Aug. 6th.

LEONARD FINDLAY.

SIR,—I was much interested in Mr. Morley's treatment of rectal prolapse (*Journal*, August 4th, p. 204), as for several years I have treated these cases by a combination of a similar method, which I once saw described in *Annals of Surgery*, with another which I saw described somewhere else. Though it is difficult to assess final results with Indian patients—who find little sense in seeing the doctor again if he has cured them, and still less if he has not—the method seems to have been successful.

One c.cm. of rectified spirit is injected submucosally at each of four points (3, 6, 9, and 12 o'clock) round the anus at a depth of $1\frac{1}{2}$ to 2 inches from the anal skin, the depth being proportionately less in a child. A silkworm-gut suture, with a large curved needle on each end, is now taken, and the rectum slung to the coccyx by a stitch passed on each side from within the rectum and out through the skin on each side of the coccyx, over which it is tied. The stitch is passed about two inches above the anus, and is left in place for about ten days. It holds up the rectum while adhesions are forming, and if any sepsis occurs round the stitch the resulting fibrosis is a help.—I am, etc.,

Dorchester, Aug. 7th.

H. WILLIAMSON,
Major I.M.S.

SIR,—Concerning Mr. A. S. Morley's valuable paper in the *Journal* of August 4th on the above subject, I was interested in his remark that many writers have stated "that cases of haemorrhoids with marked prolapse are unsuitable for any treatment short of operation except as a palliative."

In common with other physicians engaged in electrotherapy, I can vouch for the value of interrupted faradism with a sausage-shaped metal electrode, combined with rectal high-frequency, as advocated by my father, the late Dr. Samuel Sloan, a quarter of a century ago. For masses of protruding haemorrhoids ionization is a most reliable and satisfactory treatment. A zinc electrode is dipped into a 10 per cent. solution of sulphuric acid, immersed in mercury, and afterwards in water. The haemorrhoids are cleansed and treated with a solution of cocaine. The zinc electrode is attached to the positive pole, and the negative plate can be attached to the leg. A current of 6 or 8 milliamperes for six to eight minutes is applied to the pile, which should give no further trouble. Other haemorrhoids can be similarly treated every five or six days. Haemorrhoids recur after operation and after injections—or new ones appear. I have recently had a case of an old lady of 77 years whom I treated five years ago for prolapse and a mass of external

haemorrhoids. She had no pain or discomfort until a few weeks ago. Three or four treatments ought to ensure comfort for the rest of her life.—I am, etc.,

ELIZABETH SLOAN CHESSEY, M.D.

London, W.1, Aug. 8th.

Complete Prolapse of the Rectum

SIR,—I sympathize with Mr. A. S. Morley (August 4th, p. 204) in holding that the standard procedures in the treatment of this condition are far from satisfactory; nor do I feel that his method of injection will advance matters much. In India we see very many more of these cases—advanced cases—than are seen in Europe. In my early days I was orthodox, and very soon became gravely dissatisfied with orthodoxy on this question.

One morning, after returning a prolapse of six or eight inches, I observed that the rectum was a real rectum—that is, that the bend of the ampulla and anus were there no longer and that I could shove my fist up the opening in the breach. It was at once evident to me that the proximal cause of the condition was rupture of the posterior half of the perineum—that is, from the central point to the ano-rectal wall, and that there was no longer a floor of the pelvis for the ampulla of the rectum to rest upon, as in health. I thereupon incised from the central point of the perineum back to the anal margin, from which point I incised backwards around each side of the anus, well back, and dissected up to expose the levator ani, pushing the rectum well back out of the way. The floor of the pelvis was split forwards. (There is no laceration of the skin in these cases.) With a large curved needle threaded with silkworm-gut I entered through the skin, lifted the lateral connective tissue and the two borders of the levator ani muscle on it, and came down and out, lifting the connective tissue and skin on it. I inserted a sufficient number of such stitches to make the repair of the floor sound, and finished up with a few skin stitches, in all reducing the outlet so that it was rather smaller than in health.

The result was so good that I followed it in all other cases. I am convinced that the procedure is just as sound as is the repair of the ruptured perineum in the female. And why should it not be? They are both dealing with the causation, whereas the standard procedures in rectal cases do not. These cases of prolapse of the rectum are always cases of a ruptured perineum. I apologize to the orthodox.—I am, etc.,

HENRY SMITH,

Sidcup, Aug. 6th.

Lieut.-Colonel I.M.S. (ret.).

Thrombosis of Internal Saphenous Vein

SIR,—I have read with interest the letters of Dr. Stanley Parkinson (*Journal*, July 28th, p. 183) and Mr. A. Dickson Wright (*ibid.*, August 4th, p. 232) on treatment of thrombi of the internal saphenous vein. A few years ago I suffered from thrombus of this vein at the left knee. There was much swelling and oedema of the leg. A surgeon suggested rest; I asked him to remove the thrombus by ligature; he refused. I was confined to bed for over seven weeks. Then again, a few months ago I had a sudden pain in the calf of the same leg, and as the pain and hardness did not disappear in a few days I showed it to a distinguished surgeon. He told me to rest it and come to see him in three days. Under a local anaesthetic, he removed a large thrombus and ligatured the vein. The operation took about ten minutes. The surgeon told me to rest the leg and to get a locumtenent for a fortnight at least. I disobeyed his instructions, and carried on my work as usual, and had no trouble and no pain.

I thoroughly agree with the letters written that it is bad treatment to wait for a thrombus to disappear by rest, and that the ambulatory treatment after removal is

the best. The objection I have to Mr. Wright's treatment by bandaging is that you may not get rid of the varix. The vein may remain patent. In removal and ligation you get rid of the varix and prevent recurrence.—I am, etc.,
Walton-on-the-Naze, Aug 8th. J. P. DEE, M.D., D.P.H.

Treatment of Phlebitis

SIR,—In reference to the recent correspondence on thrombosis of the internal saphenous vein, may I say that for several years I have been treating phlebitis of the superficial veins of the lower extremities by bandaging and advising the patients to "keep about." An elastoplast bandage is applied from the toes to well above the upper limit of the phlebitis. All cases have been successful; the pain is quickly relieved, the patient's occupation is not interfered with, and so far there has been no instance of embolus. A doctor whom I treated in this way not only carried on with his practice, but actually played golf while under treatment. I think the above method is a great advance on the usual one of rest in bed with local applications.—I am, etc.,
London, W.1, Aug. 11th. J. D. P. McLATCHIE, M.D.

Action of Ultra-short Waves on Tumours

SIR,—At the International Conference of Radiology held recently at Zurich Dr. Reiter has reported that the ultra-short high-frequency waves of 3.4 metres have a specific action on tumours growing in experimental animals. The claims and observations he has described may be summarized as follows:

1. The ultra-short waves of 3.4 metres arrest and destroy the growth of the Jensen rat sarcoma tumour as tested *in vivo*.
2. A weak dose of ultra-short waves of 3.4 metres, applied to a growing carcinoma in mice, renders such tumours more sensitive to the lethal action of gamma rays of radium irradiated *in vitro*.
3. If a weak dose of ultra-short waves of 3.4 metres is applied to a small Jensen rat sarcoma tumour growing in living rats, the tumour is made more sensitive to the action of a weak dose of gamma rays of radium, and the growth of the tumour is arrested.

I do not agree with these observations. While Dr. Reiter has continued his work in this country at the laboratory of the St. John Clinic and Institute of Physical Medicine I have closely followed his experiments, for I have supplied him with rats and inoculated growing tumours, and also carried out biopsy and histological examination of the animals. During his experiments over 60 per cent. of the rats have died as the result of necrosis of normal tissues and sloughing of tumour, or as a result of secondary bacterial infection following ulceration and suppuration of the tissues. If the exposure to the ultra-short waves is sufficient to cause heating and necrosis of the normal tissues the tumour will also be damaged, and similarly undergo necrosis. This effect is in no way specific to any special wave-length, and the same effect can be produced by longer wave-length—4.5 metres—provided that the intensity and dosage is adequate. The same results can be obtained with the ordinary diathermy currents of 300 metres, as has been previously proved by Westermarck. If the site irradiated is thoroughly cooled, so that there is no local heating, and consequently no inflammatory damage to blood vessels or normal tissues, the Jensen rat sarcoma tumours will all grow in the normal way. The exposure to ultra-short waves causes a local hyperaemia, and stronger dosage produces inflammation and necrosis of the skin, followed by secondary infection and sloughing. The effects may penetrate through the

abdominal wall to the peritoneum or pleura, and areas of necrosis of the edge of the lobe of the liver, the kidney, and isolated areas of haemorrhage and necrosis of the intestines and duodenum are seen. The animals are collapsed and gravely ill following irradiation, and the majority die as the result of toxæmia or secondary bacterial infection following the tissue necrosis.

If it is true that ultra-short waves of 3.4 metres are specific in their destructive action on tumour cells the superaddition of gamma rays is surely unnecessary. The action of ultra-short waves is similar to other agents which damage the metabolism of cells. In this way, as Cramer and Crabtree have shown, the action of gamma rays of radium may be augmented and increased when tumours are treated with ultra-short waves are irradiated *in vitro*. However, so far as I know, the effects of ultra-short waves of longer or shorter wave-length than 3.4 metres have not been tested, so that the claim for any specific action of this wave-length remains unproven. Regarding the experiments with gamma rays carried out *in vivo*, it is possible that the hyperaemia produced may render experimental tumours more sensitive to the action of gamma rays. This fact has already been demonstrated by other means by Mottram and myself. It is, however, very premature to suggest that there is any scientific evidence to support the fact that the wave-length of 3.4 metres has any specific action on tumour cells. All the ultra-short waves appear to act in the same way as the diathermic currents of longer wave-length, and cause heating of the tissues. This view is supported by the researches of R. V. Christie and A. L. Loomis, and by Schereschewsky, who fully studied the effects of these wave-lengths on growing tumour cells.—I am, etc.,
London, W.1, Aug. 12th. ALBERT EIDINOW.

The Swab in Diphtheria Diagnosis

SIR,—One fears that Dr. James (*Journal*, August 4th, p. 230) cries in the wilderness. The practice of swabbing throats of patients seriously ill with diphtheria, instead of their immediate admission to hospital being secured on clinical grounds, has long continued to be the despair of physicians engaged in preventive medicine. Dr. James's suggestion that the opinion of one familiar with the disease should be available was also made by Dr. R. A. O'Brien (*Public Health*, August, 1934, p. 357), who, in a discussion on the control of the common infectious diseases, urged the appointment of "area diphtheria specialists," in diagnosis. Superintendents and medical officers of isolation hospitals are undoubtedly able to perform such a function, and it is to be regretted that their services are not in much greater demand in the areas which surround their hospitals.—I am, etc.,
East Ham, Aug. 11th. JAMES CRAWFORD.

SIR,—Does Dr. James seriously advise that the policy of swabbing sore throats should be abandoned? It is surely common knowledge that diphtheria may be, indeed often is, spread by "carriers," whose throats defy diagnosis clinically even by those most familiar with the "diphtheritic throat." In my experience the disease does not always follow the textbook laws of signs and symptoms. I suggest, therefore, that every sore throat is a "doubtful case" but that many do not require the expense and trouble of hospital observation or antitoxin, unless swabbing confirms their infection or infectivity. I do not wish to contend that swabbing is necessary in cases presenting the typical diphtheritic throat—it is the contacts

CORRESPONDENCE

Aug. 18, 1934]

who then require swabbing; but any policy not involving the free use of the swab is scientific heresy indeed. On the assumption, then, that prevention is better than cure, my advice to family doctors is to continue to swab not only doubtful cases, but also all contacts, and give large doses of antitoxin only to those typical cases, familiarity with which it surely did not take long in general practice to acquire.—I am, etc.,

ALISTAIR R. FRENCH.

Greenford, Middlesex, Aug. 10th.

SIR,—One question in the letter (*Journal*, August 4th, p. 230) under the above heading is most opportune. I would even go further and say that, if one is sufficiently impressed by the state of a doubtful case to take a swab, one should inject antitoxin at once. The time lost in waiting for the result of the swab examination, especially after culture, can be, and sometimes is, fatal.—I am, etc.,

PRESTON R. WALLIS.

Jersey, Aug. 7th.

Occupational Therapy

SIR,—I was much interested in Dr. A. S. Brock's comments on this subject (*Journal*, August 4th, p. 231). He states that it is not a new idea, it does not require a psychological specialist to study it, and that he referred to it in the *British Medical Journal* in 1910.

In a book which I hope will soon be published I mention it. When I became medical officer of Bradfield College in 1899, and started a country practice in the neighbourhood, I found that when a patient was on his "club" he was not allowed to do any work whatever, not even to draw water from the well in his own garden. I at once saw the necessity of getting rid of that trouble, and ordered my farm labourer convalescents to do two hours' work a day in their gardens. Also I saw at once the necessity of getting the boys some occupation when they were convalescing from measles and other complaints. That was one of the reasons why I started the Natural History Society there in 1899, and I am glad to know it is still going strong.—I am, etc.,

NORMAN H. JOY.

London, W 10, Aug. 4th.

Universities and Colleges

UNIVERSITY OF OXFORD

At a congregation held on August 4th the degree of B.M. was conferred on W. F. Fawcett.

UNIVERSITY OF CAMBRIDGE

At a congregation held on August 4th the following medical degrees were conferred:

M.D.—C. G. H. Campbell, J. K. Monro, W. G. Oakley, B. C. Tate, K. H. Uttley, J. M. Graham, A. W. Langford, M.B., B.Ch.—J. D. Ferguson, W. H. Lewis, K. Robson, A. Kekwick, A. C. Rumsey, M.B.—P. I. Cooper, C. M. Carr, R. C. F. Catterall, *A. H. Dunkerley, *M. K. Martyn, *J. Martin, W. A. Elliott, M. W. L. Owen, T. A. Ratcliffe, *C. J. Barrett, J. R. Chambers, J. G. Connell, T. B. L. Bryan, J. F. Edwards, R. E. K. Levick, C. G. Pantun, R. J. Sall, E. A. M. Halsted, L. A. Hawkins, J. P. S. Peck.

* By proxy.

UNIVERSITY OF LONDON

The following have been recognized as teachers of the subjects indicated in parentheses, and have been assigned to the Faculty of Medicine: Mr. J. H. Deggart (Ophthalmology) and Dr. G. W. Mitchell (Radiology), St. George's Hospital Medical School; Mr. M. L. Hine (Ophthalmology), Charing Cross Hospital Medical School. Probationary recognition as a teacher of bacteriology at the London (Royal Free Hospital) School of Medicine for Women, for a period of two years from July, 1934, has been granted to Mrs. Joan Taylor, M.B. B.S.

The Senate on July 18th resolved that University Readerships in Medicine, Surgery, Obstetrics and Gynaecology,

Pathological Chemistry, and Bacteriology, tenable at the British Post-Graduate Medical School, be instituted in accordance with the regulations on university titles (*Calendar*, 1933-4, pp. 235-46).

The following grants were made out of the Thomas Smythe Hughes Medical Research Fund and the Beaverbrook Fund for 1934-5 for researches to be carried out at the college or institution indicated in parentheses:

To Dr. R. C. Lightwood, the sum of £50 for apparatus, materials, and for histological and microphotographic expenses, for the continuation of haematological and pathological investigations concerning haemolytic anaemias in children, and the effects of erythrocyte stroma administration in dyshaematopoietic anaemias. (Research Department, Hospital for Sick Children.)

To Mr. T. W. Mimpriess, the sum of £34 for glass electrode apparatus, animals, etc., for an investigation into the relation of the growth of bacteria in the intestine to the hydrogen-ion concentration of the intestinal contents, in cases of obstruction in dogs. (St. Thomas's Hospital Medical School.)

The Ph.D. Degree in Anatomy has been conferred on A. A. Abbie (University College), and the Ph.D. Degree in Bacteriology on D. W. W. Henderson (Lister Institute of Preventive Medicine).

The regulations for exemption to students from other universities (*Red Book*, 1933-4, pp. 234-7), were deleted, and the following substituted therefor:

Exemption from courses of study for the First Examination for Medical Degrees and for the Second Examination for Medical Degrees, Parts I and II, in whole or in part, may be granted to students of other universities. All applications, which must be submitted on a form to be obtained from the Academic Registrar, will be considered on their merits.

Exemption from the First Examination for Medical Degrees and from the Second Examination for Medical Degrees, Part I, in whole or in part, may be granted to students who have passed all the examinations for a Science Degree of another university and to other applicants in exceptional circumstances only. All applications, which must be submitted on a form to be obtained from the Academic Registrar, will be considered on their merits.

The regulations relating to the award of a University Medal at the M.D. Examination (*Red Book*, 1933-4, p. 227; *Blue Book*, September, 1933, p. 273) and the M.S. Examination (*Red Book*, 1933-4, p. 232; *Blue Book*, September, 1933, p. 278), as amended in October, 1933 (*London University Gazette*, November 8th, 1933, p. 20), were further amended by the addition of the following words:

"or he may receive a replica of the Medal in bronze, and books to the value of the balance of the £20, selected by him and approved by the University."

It was resolved that the regulations relating to (a) the External Teacher's Diploma (*Blue Book*, September, 1933, p. 172), (b) the External Diploma in Public Health (*Blue Book*, September, 1933, p. 311), and (c) the External Diploma in Clinical Pathology (*Blue Book*, September, 1933, p. 323), be amended by the insertion after the word "Diploma" in the first sentence of each of these regulations of the words "of post-graduate standing."

Dr. F. D. Turner has been appointed governor of the Colchester Royal Grammar School.

Dr. L. W. Hackett, Assistant Director of the International Health Division of the Rockefeller Foundation, has been appointed Heath Clark Lecturer for 1934, the lecture to be given in December.

The Diploma in Public Administration has been conferred on Dr. W. E. Roper Saunders.

LONDON INTER-COLLEGIATE SCHOLARSHIPS BOARD

The following awards of Medical Entrance Scholarships and Exhibitions have been made on the results of the Board's examinations:

King's College
Warneford Scholarships: R. G. Evans (Bootham School, York); J. L. Lawrence (Sir Walter St. John's School, Battersea). *Sambrooke Scholarship*: G. T. E. Jenkins (Harrow County School).
King's College Hospital Medical School
Science Scholarship: R. P. Crick (Latymer Upper School, Hammersmith).
London Hospital Medical College
Price Scholarship: D. A. Miln (Alley's School, Dulwich)

ROYAL COLLEGE OF PHYSICIANS OF LONDON

On August 2nd licences to practise (additional to those granted on July 26th) were conferred on five candidates, whose names were printed at the end of the report of the meeting of the Royal College of Surgeons of England, in our issue of August 11th (p. 288).

Obituary

ROBERT LAWS, C.M.G., M.D., D.D., LL.D.

With the death, on August 6th in a London nursing home, of the Rev. Dr. Robert Laws—doctor, missionary, and statesman—is severed an almost distinct link with David Livingstone, but although the life-work of these two Scotsmen was centred in Africa they never actually met.

Laws was born in Aberdeen in 1851, the son of a cabinet-maker, and soon came under missionary influence. Paying his college fees with the money earned by his hands, he took the M.A. and M.D. at the University, and went to Edinburgh to attend the United Presbyterian Theological College, where he completed his course in 1874,

the year Livingstone was buried in Westminster Abbey. He at once offered for service in the mission field in Africa, but, like Livingstone, he had to wait before his opportunity arose. During this interregnum he joined the Glasgow City Mission and acted as resident physician at the small-pox hospital. In 1875 his chance came, when at the age of 24 he was chosen with seven others to go to Nyasaland and found the Livingstonia Mission of the United Presbyterian Church. After

navigating the Zambesi River in the steamboat which they had brought with them in sections from Scotland, the mission made its first station at Cape Maclear, at the southern end of Lake Nyasa, first reached by Livingstone sixteen years before. On the borders of this lake Laws spent most of his life, and for fifty-two years he was the moving spirit and head of the Livingstonia Mission.

Though he put the preaching of the Gospel before everything else, Laws found that his versatility and immense energy could also be directed into other channels. His knowledge of carpentry and building was of great use, as was his familiarity with medicine; he was the first man to administer chloroform in inner Africa, and the first to introduce coinage into Nyasaland. He was, moreover, a great advocate of education, industrial and literary. Immensely patient, the foundation of his success with the natives was systematic and thorough training, whether a man was to become a carpenter or a clerk—he was always content to wait for results. The first convert came after five years of hard work, and a year later the mission moved to the more central position on the western shore of the lake. It was at this time that Laws's activities were particularly directed towards grappling with the problem of the slave trade. It has been estimated that some 40,000 slaves were annually ferried across the lake on their journey to the coast, and the lives of those in the settlement were always in great danger from marauding Arabs as well as from the climate. The mission, however, prospered and extended westwards, until it now has 803 schools, with over 1,500 teachers and 44,000 pupils; there are also twelve hospitals and dispensaries registering 80,000 attendances a year. Industrial training has been provided for the natives in carpentry, ironwork, agriculture, milling, electrical engineering, forestry, and numerous other trades.

In 1879 Dr. Laws married Margaret Troup Gray, with whom he had been associated in his early training, and who laboured with him in Africa for forty-two years.

In 1908 Dr. Laws's missionary work was recognized by his being elected to the Moderatorship of the United Free Church of Scotland, the highest honour that this Church can bestow. The Great War caused an interruption in the mission work, which afterwards spread across Lake Nyasa into what had previously been German East Africa. In 1923 the C.M.G. was conferred upon him, and he also received the honorary degree of LL.D. from Aberdeen University. In the spring of the present year he published *Reminiscences of Livingstonia*, which contains an illuminating account of the characteristics, beliefs, and superstitions of the people in East Africa, as well as a valuable description of the flora, fauna, and physical characteristics of the country. His other publications include a translation of the New Testament into Nyanja, an English-Nyanja dictionary, and various school books in the latter language and in Tonga.

Dr. Laws was a great pioneer of Empire, and in the widest sense of the word a great doctor; his strong character and broad sympathies stood him in good stead, and his life's work was done for love of humanity at large.

[Photograph by Far and Near Press Bureau.]

WILLIAM EDWARD COLLINS, C.M.G., M.B.LOND.

Consulting Surgeon, Wellington Hospital, New Zealand

We regret to record the death, on August 11th, of Colonel the Hon. W. E. Collins at his home in New Zealand, where he had reached high rank as a surgeon and a legislator, been a pioneer worker for the Red Cross Society, and rendered valuable services to the British Medical Association.

Born in 1853 at Monghyr, India, the son of the late Dr. J. G. Collins, I.M.S., he received his education at Cheltenham and St. George's Hospital. In 1876 he obtained the diploma M.R.C.S., and in the following year graduated M.B.London. He played for England in five Rugby internationals between 1874 and 1876. In 1878 he went out to New Zealand and commenced general practice, specializing in surgery; two years later he joined the New Zealand Forces. The institution of the Volunteer Bearer Corps was in considerable degree due to his initiative. By 1896 he had reached the rank of surgeon colonel. For thirty years he was surgeon to the Wellington Hospital, and for many subsequent years consulting surgeon. Since 1904 he had been a member of the senate of the University of New Zealand, and was its examiner in surgery for three years. In 1914 he was chairman of the special committee on syphilis set up by the Australasian Medical Congress. He had been a member of the Legislative Council of New Zealand since 1907. Volunteering for service on the outbreak of the last war, he was placed in command of the hospital ship *Maheno* on her first voyage in 1915. He later commanded the hospital ship *Marama* on two commissions, and did not go on the retired list until 1920. He became president of the New Zealand Pensions Board, being awarded the C.M.G. in 1917.

An outstanding interest of his later life was the work of the Red Cross Society. He devoted many years of strenuous work to it, and contributed generously to its financial support. In recognition of his work he was elected in 1932 the first honorary life member of the New Zealand Red Cross Society. He joined the British Medical Association in 1888, and from 1901 to 1908 he was chairman of the council of the New Zealand Branch. On two occasions, in 1904 and 1916, he was president, and was elected an honorary member of the Branch in 1930. Physically strong above the average, he was a keen athlete and an enthusiastic supporter of various sports. Indefatigable and resourceful, he attained eminence in several walks of life simultaneously, his unusual breadth of outlook and capacity for co-operating with others fitting him well

for the high administrative positions he attained. He played a great pioneer part in New Zealand during its time of rapid but well-founded expansion, and leaves behind him a treasured memory.

SIR WILLIAM DONOVAN

Major-General R.A.M.C. (ret.)

We regret to record the death in London, on July 31st, of Major-General Sir William Donovan, K.C.B., late R.A.M.C., at the age of 83. Sir William was born at Killarney in 1850, the son of the late Staff Surgeon James Donovan, R.N., was educated at Fermoy College and Trinity College, Dublin, and took the L.R.C.P.I. and L.M., L.R.C.S.I. in 1871. He entered the Army as assistant surgeon in 1872, and became colonel in 1901 and surgeon general in 1904, retiring in 1909.

Sir William had a long record of war service. He obtained the medal during the Afghan War of 1879-80; he was in the Boer War in 1881, and took part in the Chitral Relief Force on the North-West Frontier in 1895, being mentioned in dispatches and obtaining the medal with clasp. In the South African War, 1899-1902, he acted as P.M.O. to the Cavalry Division, taking part in operations in the Transvaal, the Orange River Colony, and Cape Colony, including the relief of Kimberley and the actions of Paardeberg, Poplar Grove, Dreifontein, Karee Siding, Zand River, Johannesburg, Pretoria, Diamond Hill, Riet Viel, Belfast, and Colesberg. He was mentioned in dispatches in 1901 (Queen's medal with six clasps, King's medal with two clasps, and C.B.). Sir William was again P.M.O. in South Africa from 1905 to 1908, and in the Northern Command from 1908 to 1909.

In the Great War he served as D.D.M.S. of Embarkation at Southampton, during the tenure of which office he had to handle all the sick and wounded men who arrived at that port. It was his duty to allocate and dispatch them to the various hospitals having available beds, having to make up his ambulance trains from the reports received. During the battle of the Somme in 1916 he dispatched as many as 165 trains in seven days, which gives some idea of the pressure of work to which he was subjected. A contemporary describes him at this time as showing "an energy and a capacity beyond praise."

He received the K.C.B. in 1917, and also the rank of Commander of the Crown of Belgium. He was twice married, in 1909 to Anne, widow of the late Hopewell Morrell, who died in 1925, and later, in 1931, to Annie Becher, daughter of the late R. W. de la Cour, barrister-at-law. A requiem mass was celebrated at Holy Trinity Church, Brook Green, on August 3rd, and the burial took place at St. Mary's Cemetery, Kensal Green.

WILLIAM MACDONALD, M.D.

On August 3rd the town of Swansea and its neighbourhood suffered a great loss through the untimely death of Dr. William Macdonald, at the age of 55 years.

A native of Inverness, Dr. Macdonald graduated M.B., Ch.B. at Edinburgh University in 1909, and proceeded to his doctorate in 1913. His early appointments were as house-surgeon to the Queen's Hospital for Children, Hackney Road, and as resident medical officer to Queen Charlotte's Hospital. Early in 1914 he commenced practice in Swansea, and soon obtained a wide circle of patients, who also became his friends. Soon after the outbreak of war he joined the Forces, and served as a captain in the R.A.M.C. until the cessation of hostilities. On his return he was appointed to the medical staff of the Swansea General Hospital, and later he was made an honorary physician. His hospital patients were devoted

to him, and his energy and painstaking methods always won the admiration of his house-physicians. His death has interrupted a most efficient term of office as chairman of the hospital staff. Always a keen member of the British Medical Association, he made a most dignified and capable chairman of the Swansea Division three years ago. Socially he was deservedly popular, for, besides possessing a most engaging personality, he was a sound golfer and played an expert game of bridge. During the past twelve months his health had steadily failed, and those of us who realized that his condition was hopeless marvelled at his refusal to accept the inevitable, and at his remarkable attempts, even until a fortnight ago, to carry out both his hospital and his private work. He leaves a widow and two young children, for whom his colleagues and friends feel the sincerest sympathy.

Dr. CONSTANT GUSTAV LOGAN DAHNE, who died on July 28th, was born in 1866, the son of Captain F. W. Dahne and Mrs. Dahne of Clasmont, Morriston, Glamorganshire. His father was of Danish descent, and his mother came from an old Stirling family which had settled in Wales. Dr. Dahne was educated at Bishop Gower's Grammar School, matriculated at London University, and did his medical training at St. Bartholomew's Hospital, obtaining the L.S.A. in 1897. In his younger days he was a keen athlete, being a good boxer and Rugby football player, and a fine rider. Later in life he took up shooting and became no mean exponent of the art. He had practised at Pontardawe, near Swansea, for over thirty-three years, and was greatly respected there, both for his medical skill and his kind nature. He is survived by a widow and son.

Dr. SIDNEY BERNSTEIN, who died on June 30th, after a short illness, was born in Johannesburg in 1903. He was educated at King Edward VII School, Johannesburg, and afterwards entered University College, London, where he was awarded the Fellowes Gold Medal in 1925. He took his M.R.C.S., L.R.C.P. in 1926, later holding the posts of house-surgeon, registrar, and first assistant to the ear, nose, and throat department at that hospital. He was also house-surgeon and assistant registrar to the Central London Throat, Nose and Ear Hospital, and house-surgeon and casualty officer at the Royal Northern. At the time of his death he was surgeon to the ear, nose, and throat department, Gloucestershire Royal Infirmary, surgeon to the Gloucester County Mental Hospital, Gloucestershire Joint Tuberculosis Hospital, Gloucestershire Fever Hospital, Lydney District Hospital, and Gloucester District Nurses' Society. Dr. Bernstein was a member of the British Medical Association, in which he took a keen interest, a Fellow of the Royal Society of Medicine, and a member of the otology and laryngology section, on which council he had just been elected. He came to Gloucester in October, 1929, on the death of Mr. Smurthwaite, and by hard work built up the present ear, nose, and throat department in the new buildings of the Infirmary, which buildings owe so much to his valuable advice and foresight. He was a very hard worker, and this probably had much to do with his early death. He was a loyal colleague, loved by his fellow practitioners, and listened to with interest. He endeared himself to doctors and patients alike by his personality, charm, and kindness. He leaves a widow, to whom we offer our deepest sympathy.

The following well-known foreign medical men have recently died: Dr. CLEMENT CLEVELAND of New York, past president of the American Gynaecological Association and of the New York Obstetrical Society, aged 90; Dr. ARNANDO ANGELUCCI, professor of ophthalmology at Naples; and Dr. LOUINIÈRE HARWOOD, dean of the medical faculty of the French University of Montreal and professor of clinical gynaecology at the Hôpital Notre Dame.

The Services

THE SERVICES

[THE BRITISH
MEDICAL JOURNAL]

DEATHS IN THE SERVICES

Colonel John Garvie, K.H.S., Bengal Medical Service (ret.), died at Bideford on July 24th, aged 71. He was born on May 3rd, 1863, the son of William Garvie, manufacturer, of Perth, and was educated at Edinburgh, where he graduated M.B., C.M. in 1885. Entering the I.M.S. as surgeon on March 21st, 1887, he became colonel on March 24th, 1917, and retired on March 25th, 1922. He was appointed honorary surgeon to the King on June 20th, 1920. He served in the Zhoib campaign on the North-West Frontier of India in 1890.

Lieut.-Colonel George Speirs Alexander Ranking, C.M.G., Bengal Medical Service (ret.), died at Caversham on July 14th, aged 82. He was born at Hastings on January 9th, 1852, the son of Robert Ranking, Esq., surgeon, and was educated at Aldenham School, Herts, at Bart's, and at St. Catherine's College, Cambridge, where he was a scholar. He took the M.R.C.S. and L.S.A. in 1874, and graduated at Cambridge as B.A., with honours, in the Natural Science Tripos, in 1873, as M.B. in 1875, and as M.D. in 1879. I.M.S. as surgeon on March 31st, 1875, passing first out of Netley, where he won the Herbert prize; became surgeon lieutenant-colonel after twenty years' service, and retired with an extra compensation pension, on May 31st, 1905. During his first years of service he served for some time in the Bengal Cavalry; in 1892 he acted as professor of chemistry in the Calcutta Medical College, and as chemical examiner to the Government of Bengal; and in 1898 he held the post of surgeon superintendent of the Presidency European General Hospital, Calcutta. From early in his service he devoted himself to the study of Oriental languages, and from 1894 to 1905 held the post of examiner to the Government in Oriental languages, and assistant secretary to the Government of India. He was the author of many works on Oriental languages: *Hidayatu-l-Hukuma*, 1878; *Arabic and Persian Prosody*, 1885; *Tahm-i Zabani-Urdu Dictionary*, 1905; edited and translated *Tawarikh-i-Badaoni*, 1889; and one small professional work, *On Preservation of Health in India*, 1903. After retirement he settled at Oxford, where he was lecturer in Persian from 1909 to 1920. On March 15th, 1909, he was appointed lieutenant-colonel in the R.A.M.C. (T.F.), and commandant of the Third Southern (Oxford) General Hospital, a post which was probably considered a sinecure at the time, but became one of hard work and of great importance during the war. He was mentioned in dispatches in the *London Gazette* of July 27th, 1917, and received the C.M.G.; and later the Territorial Decoration in 1923. He retired from the Territorial Forces on September 19th, 1923. In 1875 he married Elizabeth Maunsell, daughter of John Duncan, Inspector-General, Royal Irish Constabulary. She died in 1927, leaving one son.

Lieut.-Colonel George Henry Baker, Bengal Medical Service (ret.), died at Bournemouth on May 22nd, aged 74. He was born on May 11th, 1860, the son of George Philip Baker of Portsea Island, Southampton, was educated at Charing Cross Hospital, where he was Golding scholar, and took the L.S.A. in 1884 and the M.R.C.S. in 1885. Entering the I.M.S. as surgeon on October 1st, 1885, he became lieutenant-colonel after twenty years' service, and retired on December 24th, 1913. Most of his service was spent in civil employ in the United Provinces. He served in the Burmese campaign of 1886-7, in the 6th Brigade, and received the frontier medal with a clasp; and in the Tirah campaign of 1897-8 (medal with clasp). After retirement he rejoined for service in the war of 1914-18.

Major Robert O'Kelly, R.A.M.C. (ret.), died at Crecon, County Limerick, on June 14th, aged 49. He was born on January 16th, 1885, and was educated in Dublin, where he took the L.R.C.P. and S.I. in 1907. Entering the R.A.M.C. as lieutenant on February 4th, 1908, he became major after twelve years' service, and retired, on account of ill-health, on March 30th, 1927. He served in the war of 1914-18.

Major John Hay Duguid, R.A.M.C. (ret.), died on May 27th, aged 57. He was born on July 13th, 1876, and was educated at Aberdeen, where he graduated M.B., Ch.B. in 1901. Entering the R.A.M.C. as lieutenant on January 31st, 1903, he became major on October 31st, 1914, and retired on February 10th, 1923. After retirement he was in practice at Walford. He served in the war of 1914-18.

Medical News

The annual dinner of the Chartered Society of Massage and Medical Gymnastics will be held at the Café Royal, Regent Street, W., on Wednesday, September 26th, at 7.30 p.m.

The programme for the fifty-third post-graduate course of the Medical Faculty of Vienna has now been issued. This course will extend from September 24th to October 8th, and will deal more particularly with recent advances in general medicine and therapeutics. Copies of the programme can be obtained from the office of the Medical Faculty in the University, Ring des 12 November, Vienna 1.

The next lecture-demonstration arranged by the Fellowship of Medicine and Post-Graduate Medical Association (1, Wimpole Street, W.) will be given by Dr. Clark-Kennedy, at 11, Chandos Street, W., on August 21st, at 2.30 p.m.; the subject will be asthma. The following lecture will be on August 28th, on loss of voice. Forthcoming courses include infants' diseases at the Infants Hospital, September 3rd to 15th; chest diseases for the specialities at the Westminster Hospital, September 17th to 29th. The Panel of Teachers provides daily instruction in various branches of medicine and surgery.

The Fellowship of Medicine announces that a course in infants' diseases, specially arranged for medical officers of welfare centres and others interested in nutritional disorders and dietetics, will be given at the Infants Hospital, Vincent Square, Westminster, S.W., from September 3rd to 14th. The fee for the full course is £3 3s., and the names of qualified practitioners wishing to attend the course (the number is limited to fifteen) should be sent to the Secretary, 1, Wimpole Street, W.1, by August 30th.

The first International Congress of Electro-radiobiology will take place from September 10th to 15th in the Doge's Palace at Venice under the presidency of the Marquis Guglielmo Marconi and Count Giuseppe Volpi di Misurata. The object of the congress is to hold joint discussions between physicists, chemists, biologists, and physicians, on biological actions of all radiations, in order to co-ordinate the respective investigations, in order to learn from the physicist the theoretical and experimental basis of physical researches on the vibratory and corpuscular phenomena. The physicist what are the influences that these phenomena have on cellular elements, on complex tissues, and on organic processes. The applications of radiations to medicine will not be examined and discussed. Further information may be obtained from the general secretary of the congress, Dr. Giocondo Protti, S. Gregorio 173, Venice, Italy.

The thirtieth congress of the Italian Society for Otorhino-laryngology will be held at Padua from September 6th to 8th, when the following subjects will be discussed: the surgery of the ethmoid, introduced by P. Carco, G. Lugli, and M. Silvagni; and the lymphatic tissue and its importance in the development of laryngeal tuberculosis, introduced by R. Motta, G. Salvadori, and V. Tanturri.

The fourth congress of the Latin Oto-rhino-laryngological Society will be held at Brussels from September 20th to 25th under the presidency of Dr. E. Buys.

The eighth congress of the French societies of otoneuro-ophthalmology, which was to have been held at Barcelona this year, has been postponed to next Easter, when it will probably be held at Nice.

The Industrial Welfare Society (14, Hobart Place, Westminster, S.W.1) has issued a pamphlet on the scope, administration, equipment, and staffing, etc., of works laundries.

Major-General D. J. Collins, C.B., C.M.G., D.Sc., M.D., has been appointed a deputy lieutenant for the County of London.

AUG. 18, 1934]

LETTERS, NOTES, AND ANSWERS

After providing for a bequest of £500, the will of Mr. Gerald B. Atkins, Brentmead Place, Hendon, who left £11,041 (net personalty £10,035), leaves the residue upon trust to pay the income between Guy's Hospital, St. Bartholomew's Hospital, Moorfields Eye Hospital, St. George's Hospital, and the Mildmay Maternity Nursing Association. If either ceases to exist or ceases to be supported by voluntary contributions by reason of its being taken over or run by the State or the L.C.C., or any local or other authority or public body, such interest is to cease.

An institute of public health has recently been founded in Rome, consisting of laboratories for chemistry, bacteriology, biology, and sanitary engineering, a library, and a museum.

By a recent ministerial decree every cinema in Spain has been ordered to exhibit films of a public health character, supplied by the Subsecretary of Health and Welfare, for at least twelve minutes at each performance.

Geh. Med. Rat Professor Emil Abderhalden, director of the Physiological Institution of Halle University, has been elected a corresponding foreign member of the Vienna Academy of Sciences.

Dr. J. L. Faure, professor of clinical gynaecology, and Dr. Brindeau, professor of clinical obstetrics, in the Paris Faculty of Medicine, have been elected members of the Académie de Médecine.

Professor Emile Gallemaerts, a former president of the Belgian Académie de Médecine, has been nominated an officer of the Legion of Honour.

that this can be induced to nail reactivity by fine, minute punctures of the scar tissue, stage by stage, and dressing with iodox?

Nail-biting

"LIBERTAS," in reply to "M.B.Ed." (August 4th, p. 240), writes: Let the child of 11 years old be shown daily that her nearest and dearest care. Let her be shown that the cure is in her own hands, and that the habit is her slave and not her master. Let her be told gently and in confidence that other habits—for example, masturbation, lurk ready for the uncontrolled. If still necessary, when much older, let her know that nail-biting is among the possible symptoms of mental deficiency.

Dr. A. G. BUCHANAN (London), in reply to "M.B.Ed.," writes: I have cured a large number of cases of nail-biting by hypnotic suggestion.

Major H. WILLIAMSON (Dorchester) writes in reply to "M.B.Ed.": I recently had a similar case, which was cured when the child's mother gave her a manicure set and taught her to take a pride in her nails. The set included "liquid nail polish," which particularly pleased the child, and a pair of nail clippers which could be used with either hand.

Insect Bites and Iodine

Dr. T. M. CUTHBERT (Gidea Park) writes: I can endorse Dr. Pringle's finding. All my cases of septic insect bites have been "first-aided" with iodine. One had commencing erysipelas when first seen four days after the bite—the patient died from septicaemia. I feel sure iodine ought not to be applied to insect bites, but it seems a universal treatment, probably originating in a newspaper article.

Spermatorrhoea when Bathing

Dr. ALISTAIR R. FRENCH (Greenford) writes in reply to "M.D., D.P.H.'s" inquiry concerning the above condition: I suggest that he might obtain some help from the perusal of Dr. Max Huhner's book *Disorders of the Sexual Function*, published by the F. A. Davis Company of Philadelphia.

Over-smoking

"A. K." (Gravesend) writes: In reply to your correspondent's inquiry on this subject, it may be of interest to record the following instance in which I was successful in effecting an improvement. Some time ago, having to meet an in-coming ship, I noticed on the bridge a bowl containing numerous cigarette ends. The captain, whose hands were very shaky, and who admitted that he should cigarette smoking, agreed to my suggestion that he should substitute caramels for the smoking of cigarettes. The next time I saw him on his ship the bowl was full of caramel wrappings instead of cigarette ends. His hands were steady and his smoking had been reduced to a very moderate amount.

Dr. E. N. SAYWELL (London, N.W.1) writes: Has "F. C. R.'s" patient tried complete abstinence from tobacco for forty-eight hours? I know of several cases completely cured of the craving by this means. If the patient wishes to continue moderate smoking, Paton, in his *Hormone Therapy*, gives a remedy which he has found efficacious, but I have not tried it.

G.P. Laboratory Equipment

"W. F." writes in reply to "Q. R. S.'s" inquiry (*Journal*, June 2nd, p. 1015): The following information may be of use to your correspondent. An egg incubator, which can be bought second hand, working with gas or oil, is perfectly efficient; regulators and lamp heaters can be obtained which keep a very good and regular temperature. For a sterilizer a "pentecon" may be used; size 5 is, however, too small. There is an efficient centrifuge, made in Germany, which is quite cheap; test tubes 1/2 in. by 5 in. are suitable, and smaller Wassermann tubes can also be used. Of dyes, the dried media are useful, and, if one only uses small quantities, cheap. The "tabloid" brand is again to be recommended. Storage trouble can be diminished by cutting slides into three and mounting temporarily on another slide for examination. Sedimentation tubes, which can be made at home, are cheap to buy. A home-made colorimeter can be made from plasticine with a screen of paper having slots cut in it. Suitable measuring apparatus can be obtained from Baird and Tatlock. As regards renal function tests, it is better to buy the tube. Bromine can be obtained in ampoules of 1 c.cm., and four samples can be examined with

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to The EDITOR, British Medical Journal, B.M.A. House, Tavistock Square, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication. Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111 (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are:

EDITOR OF THE BRITISH MEDICAL JOURNAL, Aithology Westcent, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate Westcent, London.

MEDICAL SECRETARY, Mediseera Westcent, London.
The address of the Irish Office of the British Medical Association is 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh).

QUERIES AND ANSWERS

Regeneration of Nail Tissue

F. F." (Bromley) has a case in which, owing to an accident some two months ago, the skin on the dorsum of the thumb was caught and wrenched up just above the nail matrix. The entire nail was pulled up off its bed and dragged up to the pulp of the thumb, the flap involved remaining attached. At this stage "F. F." saw it, and replaced the flap. Subsequently the entire remains of the thumb nail appeared to be fine scar tissue. The matrix is by what seems to be fine scar tissue. The matrix is proliferating a new nail from the proximal end of the scar tissue, or nail groove, and the nail is being reproduced from the sides of the nail groove (more so from the inner side). There is, however, a comparatively large area of the scar tissue in the nail groove which does not, so far, show signs of proliferating nail. Is it likely that there is a stratum of nail epithelial cells below this scar tissue, and

each ampoule. Capillaries made from broken test tubes are useful for doing coagulation times. Sugar estimations are easily done with a burette and Benedict's solution in a dish. There is a cheap blood nitrogen set on the market. Analysis of stomach contents is quite simple to do with indicators and the burette: solutions are easily made up. For the laboratory bench, a kitchen table, equipped with spirit-lamp and bought test-tube racks, suffices. Glass slides rubbed with sandpaper and turpentine give a good surface for writing labels. A sheet of glass should be fixed on the table, with paper, half white and half black, gummed underneath.

Pruritus with Jaundice

Dr. J. WATKIN EDWARDS (London, S.E.20) writes: I am interested in the inquiry made in the *Journal* of June 16th concerning the treatment, or relief, of pruritus associated with jaundice, and am reminded of a case which came under my observation some years ago in a patient who had been a medical student in London. This man had an attack of jaundice (after fish or pork, I forget which), very marked, and complicated by this maddening itching of the skin, which nearly drove him frantic. I tried the usual treatment for catarrhal jaundice, and soothing applications to the skin, with very unsatisfactory results. After a few days, finding no improvement, he expressed a wish to come to London to see one of his old teachers. I readily consented, and he chose that his old physician the late Sir William Broadbent. After an examination, Sir William assured him that the itching would have disappeared by the next day. Although it is now many years ago, I distinctly remember that the chief ingredient in the prescription (which definitely did remove the pruritus by the next day, and without any relapse) was sodium phosphate. This good old-fashioned medicine is rather badly neglected in these days. I have never forgotten its usefulness in the above case, and often find it valuable in liver troubles. I write this letter in the hope that it might be of some value to revive the use of a good medicine and to meet the needs of your correspondent "P. J. M."

Income Tax

Assessment in Excess of Return

"SENEX" made a return and has been assessed in excess of the amount returned. (Apparently the "demand note" to which he refers was a formal notice of assessment issued to give opportunity for objection to be lodged.) He has been requested to supply particulars of expenses—and presumably a statement of gross receipts—but the inspector will not say how the original assessment "made by commissioners" had been arrived at.

* There are two bodies of commissioners, who sit at infrequent intervals: (a) the additional commissioners, who are responsible for the making of assessments; and (b) the general commissioners, who hear objections thereto. If the former did not have the return when the assessment was made, or thought it inadequate, they would make an assessment on estimate. Presumably something of that sort happened. "Senex" was formally notified, and now has the alternative of coming to an agreement with the inspector or of appealing to the general or special commissioners, who will personally consider any evidence he may wish to put forward. We suggest that a personal discussion at the inspector's office will probably be the best way of reaching a proper settlement.

LETTERS, NOTES, ETC.

A Campaign Against Rats

An account of their campaign against rats in Beyrouth, where bubonic plague has been endemic for more than a decade, is given by L. V. R. JUDÉ and J. V. H. LUBER in *Arch. de Méd. et de Pharmacie Militaires* for February, 1934. In 1920 there were sixty-two cases, in 1921 there were twenty, and in 1932 as many as forty-nine cases. The campaign included all the measures hitherto advocated. Among 214 rats examined between May, 1932, and September, 1933, eleven were found to be infected. Although rats were destroyed by the thousand by trapping, etc., it was realized that for a town with a population of 200,000 inhabitants something more radical must be done. Preliminary tests were accordingly made with the Danish virus ratin, and with the highly toxic preparation of squill, known as ratin. The system adopted was to distribute the bait, impregnated with ratin, all over the town, and, after three weeks, to provide the survivors with bread, fish, or cheese impregnated

with ratin. A credit of 200,000 francs was provided for the purchase and distribution of these two poisons, and fifty persons were employed on the preparation of 12,000 baits every day. They were put down in the evening, and the few that were left untouched were removed next morning. In the course of one year three million such baits were distributed. The exploration of certain burrows revealed many dead rats, whose bodies had dried up without smelling of decomposition. Though no exact figures could, of course, be quoted, it was the unanimous opinion of the inhabitants that the rat population had been greatly reduced. During 1933 there were only four human cases of plague—a result which the authors are inclined to attribute to their vigorous campaign against Beyrouth's rats.

"Revue de Rhumatisme"

Recently a new periodical, devoted to the study of rheumatism, has been started in France, under the title of *Revue de Rhumatisme*. The policy of the editors is to include authoritative articles, by well-known specialists, on rheumatism, reports of societies and abstracts of articles on rheumatic subjects, and reviews of appropriate books. The first number contains a long article by Drs. Fernand Bezançon and Mathieu-Pierre Weil on the pathology of joints. This must prove a most valuable summary of recent views on the influence of capillary circulation and the autonomic vascular control are summarized, and the differences in the pathological process underlying osteoarthritis and rheumatoid arthritis are described. From these considerations the rationale of modern treatment held for the future success even in this chronic and disheartening disease. We welcome this venture, and hope that it will contribute to the relief of the social scourge which is its subject.

A Family Record of Hospital Service

There has recently been issued a revised list, alphabetical and local, of the old students of St. Thomas's Hospital, S.E.1. The compilation of this book has been the work of Robert S. Hopkins, School Bedell, and this number represents his last effort before retiring, on August 11th, after fifty-four years of service to the hospital. A London correspondent writes: Hopkins's family holds a remarkable record at St. Thomas's: in 1880 he himself was appointed as a messenger at the age of 14, his father served as porter from 1843 to 1880, while his grandfather, who worked in connexion with the medical school at the old hospital in St. Thomas's Street, was employed from 1823 to 1843. The combined services of the family thus cover 111 years. During his fifty-four years Robert Hopkins has worked for six medical secretaries, while a wealth of student material has passed through his hands. He is rightly credited with an almost infallible memory for names and faces, and he recorded that however much time may have elapsed since he last saw an old student he never fails to recognize him. One mistake is, however, alleged in the case of a tw brother, but even this has been denied.

High Carbohydrate Diets and Insulin Efficiency

A Correction

Dr. H. P. HIRSWORTH writes: In my article on the above subject, which appeared in the *Journal* of July 14th, 1934 (p. 57), I have unfortunately made a mistake in the references. The second reference, concerning the glucose equivalent of insulin, I attributed to F. M. Allen; it should really have been attributed to F. M. Allan of Lahey Clinic, Boston. Dr. Allan has drawn my attention to this error, and I should be grateful if you could publish a correction of my mistake.

Correction

Professor F. J. BROWNE writes: Will you please let me, in justice to the Central Midwives Board, correct an error that has crept into my paper "Are we Satisfied with the Results of Ante-natal Care?" published in your issue of August 4th, on page 196. The percentage of failures in the examinations of the Central Midwives Board is there stated as ten. This should be seventeen.

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 34, 35, 36, 37, 38, 39, 42, and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 40 and 41. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 148.

BRITISH MEDICAL JOURNAL

LONDON: SATURDAY, AUGUST 25th, 1934

CLOSED ANAESTHESIA*

BY

W. B. PRIMROSE, M.B., CH.B.

SENIOR ANAESTHETIST, ROYAL INFIRMARY, GLASGOW; SENIOR ANAESTHETIST, PRINCESS LOUISE
HOSPITAL FOR EX-SERVICEMEN, ERSKINE

Closed anaesthesia has lately been attracting considerable attention, and investigation shows that many workers have interested themselves in this method during the last few years. The present discussion of this method is entirely due to the thought and experiment of these workers, not all of whom have published their views and results. It may be as well first to state what is meant by the term "closed anaesthesia," for, as it stands, it does not convey very much in the way of definition or of special meaning. Most anaesthetists are accustomed to conduct general anaesthetics which cannot be described otherwise than as "closed," so that some definition of the term is required to indicate the special light in which this form of anaesthesia has now come to be regarded.

Closed anaesthesia is general inhalational anaesthesia maintained indefinitely by the continuous rebreathing of a relatively small fixed amount of anaesthetic gas, which is constantly kept in a respirable and life-supporting condition. This definition implies some special treatment of the gases in the closed system by which the anaesthetic gas is recovered in a state of purity for reinhalation. The closed system may also be called the "recovery principle," which term conveys the additional fact that the anaesthetic gas is recovered from the breath, is used over and over again by the patient, and is not allowed to escape into the general atmosphere during the anaesthesia.

Gas-recovery is not new, the absorption of carbon dioxide from the breath being well known as a method employed in physiological research, as also is the fact of the chemical stability of the anaesthetic gases. It is not remarkable, therefore, that the idea of applying these facts to the management of gaseous anaesthesia should have occurred to many workers both at home and abroad. What does seem strange, however, is that the principle of carbon dioxide absorption, which seems so simple and effective, has not produced more decided results and established itself as a workable and reliable method.

The idea presented itself to me originally less as a method of using the anaesthetic gases with improved effect than as a means of making gas-oxygen apparatus portable. The construction of apparatus of manageable weight had interested me for several years, but there seemed to be no means by which cylinder dead weight might be reduced until the recovery principle was thought of and tried. With this scheme working successfully, it should be possible to make a really portable apparatus, since it would no longer be necessary to carry about the large supplies of gases required by the "flow" principles.

There might also be other advantages from the working of a completely closed system.

Mechanical Difficulties of Administration

At the outset it was seen that there would be no great difficulty in making a machine that would be gastight, but would it be possible to get the necessary security of joint between the machine and the patient? This was a matter of great importance, for, if leakage could not be controlled, the system could not be kept completely closed, which is a condition demanded by the recovery principle. On reviewing the various instruments which have been described, I cannot help thinking that this joint between the machine and the patient has proved a great difficulty, and, from my experience in dealing with it, there seems to be little doubt but that this detail has held up the development of this method from the beginning.

A very early conclusion reached by me was that the joint could not be maintained for the purposes of the principle by any means applied to the face. A mask might be necessary for induction, but other means would have to be used to maintain the closure of the system upon which the recovery principle depended.

Gas Supply Connected Directly with Pharynx

The obvious solution to this problem appeared to be the fitting of some tubular device into the pharynx immediately behind the tongue, the tube having an inflatable cuff or tyre at its free end for making contact with the pharyngeal wall upon distension. Experiment at once showed this to be quite feasible.

It was found that such a device, when made to correspond with the general configuration of the throat, filled the cavity completely, and, by being made to expand laterally, did not open the oesophagus as might be expected. When connected with the instrument this gastight joint was capable of withstanding all the higher pressures used, even up to 30 mm. Hg without leakage. This throat tube therefore provided the means for joining up the patient with the machine, and so fulfilled the condition of complete closure.

An outstanding difficulty in connexion with the making of this tube was to find the rubber which, in a tyre of the small size required, would stand the inflation often needed for capacious throats. Elasticity of rubber is apt to be variable, with the result that a weak spot may develop with use, and soon rupture. This difficulty threatened failure for a considerable time, but ultimately a suitable rubber was found, which was more than equal to the conditions imposed upon this small tyre, and the tube is now manufactured successfully by the India Tyre and Rubber Company of Inchinnan. The rubber used is

* Read in opening a discussion in the Section of Anaesthetics at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

remarkably durable, and is capable of doing many dozens of cases; in fact, I have not yet reached the limit of durability of a single tube which is used for almost every one of my cases, and which is boiled after each occasion. This property of sterilization by boiling is unique for rubber, and of the utmost importance in the use of such an instrument.

Absorption of the Carbon Dioxide

Another matter requiring consideration was the most suitable method of absorbing the carbon dioxide. Generally speaking, there are two methods in use: (1) the granular or dry method, using a soda-lime compound, which operates most successfully as an absorbent in the various kinds of respirator, particularly those which have to be carried about on the person; and (2) absorption by means of a strong solution of caustic soda or potash. The latter method is impossible for use for most purposes, yet the special conditions of general anaesthesia make it the most suitable.

The solution is undisturbed during use, so that there is no danger of its escaping into different parts of the tubular system, and its avidity for carbon dioxide is high and very constant at all rates of breathing. It is also possible to apply a simple test to the solution to ascertain the need or otherwise for renewing it. This latter is a point of importance, particularly in hospital practice, where an anaesthetist may wish to use a machine, the absorbing capacity of which may be quite unknown to him. This estimation is a very uncertain matter with even the coloured granular absorbents when used occasionally as in the case with anaesthetic apparatus, and their use entails considerable waste under these circumstances.

Simple Method of Estimating Limit of Absorption

The devising of a suitable test for the limit of absorption of the liquid gave some concern, for the usual double titration method of estimating the increasing percentage of carbonate as it formed was quite unmanageable by the anaesthetist who wanted to use the machine without delay. The method also failed to operate after a little over 16 per cent. of carbonate was formed, for in the cold solution crystallization took up the excess over this figure. For the purposes of the anaesthetist it was necessary that a result be quickly arrived at by simply adding a sample of the absorbent to an indicating reagent of some kind. This was finally achieved by modifying the double titration method, and the test now consists of adding 1 c.cm. of absorbent to 1 c.cm. of 80 per cent. hydrochloric acid in water, using two drops of phenolphthalein as indicator. If the purple colour remains the solution may be used for at least two hours. If the colour is discharged the solution should be changed, although it is not actually exhausted.

This point of discharge was fixed arbitrarily by ascertaining when the absorbing solution allowed 3 per cent. of carbon dioxide to remain unabsorbed from exhaustion of the soda, and, considered along with the lowered metabolic activity of the average case during an anaesthesia, it provided a good margin against the point being overreached. The machine has also another means of dealing with such possible oversight. As the unabsorbed carbon dioxide accumulates along with the other gases the pressure in the system rises, and relief is given by the blow-off valve.

A Machine for Administering Closed Anaesthesia

A machine constructed according to the foregoing principles is exhibited here and known as "anaesthetor M 7." It represents the results to date of my investigations into the recovery or closed method of using the anaesthetic gases. It consists of a basal part, which is the absorbing tank, on the removable lid of which are

mounted the tubular and valve parts, sight-feeds, etc. In front are the two turret valves which interrupt the metal part of the respiratory tube for the purpose of diverting the breath through the ether chamber, absorbing tank, or both, or of directing it straight through to the breathing bag at the extreme left end of the tube. At this point also are seen the blow-off valve, which consists of a spring-loaded ball capable of adjustment, and also the nitrous oxide inlet. Behind are the sight-feeds for the anaesthetic gas and the oxygen; these are of simple design, for in the closed system there is no measuring or portioning of the gases, since they do not flow as in the other methods. The stable nitrous oxide is an atmosphere like the nitrogen of the air, and is therefore absolute; oxygen is merely added to the requirements of the patient as these vary. The other fittings are, the ports to the ether chamber and the absorbing tank placed at either corner behind, and the level and levelling screws seen in front.

The lid is removable from the absorbing tank by undoing the six straining clips, and, when removed, reveals the shallow ether chamber and the baffle, which is fixed to its underside, and surrounded by four limiting walls. The baffle divides this box-like space equally but irregularly into two parts, each of which communicates with one of the two passages seen to lead up to the turret valve above. The free edge of this baffle is deeply serrated throughout its length by triangular serrations. These, along with the surface of the solution into which they dip almost entirely, constitute a device whereby a series of apertures is formed through which the breath has to pass as it moves through the machine. These triangular apertures vary in their size with the volume and the strength of the breath passing through them, and, being open below, cannot become occluded with crystals of carbonate as happens with round holes. It is the need for the even dipping of this baffle into the solution that necessitates the use of the level and levelling screws.

The absorbing tank works with one litre of solution, which may be made up in the tank by dissolving the contents of a 1 lb. tin of caustic soda in a sufficiency of water, and, when cool, filling up with water to the line marked on the inside. The baffle is arranged to work only with this amount, as it ensures effective absorption with the lowest resistance to the breathing. This quantity of solution keeps the unabsorbed carbon dioxide down to 1.5 per cent. for about eight hours, after which it slowly rises until the test gives indication that the 3 per cent. point is passed. Ten anaesthetic hours represents the usual range of absorption of this amount of solution.

The apparatus is connected with the patient by the corrugated rubber tube, which ends in a swivel-valved joint. To the rotating part of this joint can be attached a mask for induction purposes at one point, and the throat tube for the maintenance of the anaesthesia at the other, with, of course, provision for breathing to the air. Attached to a small nipple on the inside of this valved joint is the delivery tube from the oxygen sight-feed, which is seen to enter the side of the respirator tube. By this means oxygen is supplied directly to the mouth of the patient. A mouth prop of oval tubular pattern keeps the mouth open during induction for the passage of the throat tube at the proper time. This prop is held in place by the sponge rubber covering of the mask, so that it cannot be ejected by the patient as he "goes under." The throat tube is in two parts: a rustless steel oval wire coil fixed to a coupling, and a rubber tubular covering which is pulled over the coil and also fixed to the coupling by a rubber ring. The free end of the rubber tube shows the tyre from which the small inflating tube passes along one side to end in the strong pressure tube, to which the inflating bulb is attached when in use.

Aug. 25, 1934]

The Machine in Use

From what has already been said certain preliminaries are essential before attempting to use the machine. In the first place, the absorbent must be tested unless it is known that this is unnecessary: ether should show on the indicator seen through the glass top of the filler cap, and the gaseous supplies must be adequate and under complete control. When placed beside the operating table the instrument must be levelled by using the screws at each corner in front. A bagful of gas may now be admitted, and then forced through the absorbing tank by hand pressure to remove as much of the air as possible, and also any ether that may have been left from the previous case. The swivel valve at the end of the respirator tube allows of this "washing through" when set to either extreme position, but when set to "air" the machine is closed, and may now be filled with gas ready for use.

With the mouth prop in position, induction is effected with the mask. Breathing on "valves" is secured by having the absorber "on"; the small resistance so set up to expiration causes the breath to escape through an expiratory valve on the mask. Closing this valve stops off a trace of ether when required, the throat tube, previously assembled, is fitted to the swivel valve, and, at a suitable moment, is swung round and inserted into the throat, where the small tyre completes the joint on being inflated. After this the nitrous oxide will be turned off unless raised pressure is required; the oxygen will be regulated to suit the requirements of the patient, and ether used to suit those of the surgeon; and in the average case the absorber will be turned "on."

When anaesthesia is established the first point to require attention will be the throat tube. It is necessary that the tyre be not over-distended, and to avoid this one finds the lowest sealing pressure. In one case over-distension which inadvertently occurred, and was allowed to continue, resulted in some pharyngitis, which, however, soon passed off, but the experience provided the lesson in its avoidance. The lowest sealing pressure is easily found by deflating the tyre until breath is heard to escape in the throat, when one pressure of the bulb will close the joint. The joint may be tested in this way once or twice during a lengthy anaesthesia; the muscles of the pharynx tend to relax as time goes on, and to accommodate themselves to the tyre more readily, so that combined with lower pressure in the instrument, less tension is required in the tyre. Attention of this kind ensures the complete absence of pharyngeal irritation, even after prolonged anaesthesia. A special soapy lubricant made by Allen and Hanburys facilitates the insertion of this tube, but no oily or greasy matter should ever be used, as these substances attack the rubber very quickly.

When the closed system has been established and the patient is breathing quite clearly, relaxation—for example, of the abdominal muscles—will call for the use of ether. Along with this the pressure of the gases should be raised by admitting nitrous oxide up to pressure indication. This pressure may be as great as 20 mm. Hg, or even more in the case of a very strong man suffering from an acute upper abdominal lesion. Pressure greater than this usually stops breathing, however, especially as the ether takes rapid effect, and embarrassment to the breathing must be removed by lowering the pressure. With the production of relaxation the ether is discontinued, and the pressure maintained at about 10 mm. If further effect is required, say, to close the abdomen, it is better to add a little more ether than to use raised pressure again.

The further use of much ether or pressure is rarely called for owing to a peculiarity of the closed system. The ether that has been added to it in the early stages of an operation mostly remains in it, except for a little that is absorbed into the tissues. In many cases the ether tension in the patient's circulation and in the machine would appear to become stabilized and to remain uniform. The patient's vitality in these cases does not remain constant but diminishes, and in so doing makes him more susceptible to the etherized atmosphere. Relatively to the patient, therefore, the original effective dose of ether now becomes an overdose, as shown by the depressed breathing with inspiratory tugging of the chin and the dilating pupils.

This situation, so easily seen developing in such cases, is as easily dealt with and corrected. The breathing bag is emptied by hand pressure through the blow-off valve, and filled with fresh gas. Ether is exhaled into this gas, which may be renewed once or twice more at four- or five-minute intervals. Normal conditions are soon re-established, and a more definite gas-oxygen anaesthesia supervenes until the end of the operation.

This relative overdosage makes its appearance slowly, as a rule, and some time after the ether has been turned off. It seems to occur in patients of the nervous type, whose reserves of nerve energy are not great. In the stolid types of patient the ether used is absorbed to a much greater degree, so that light anaesthesia tends to supervene, with its vigorous breathing and smallish pupils. This lightness of anaesthesia may also be detected by turning on the ether full for one breath or so, when its irritating effect on the larynx produces a kind of grunting on expiration. A few breaths of ether stop this noise, and restore the deeper state of anaesthesia. Occasionally a patient may phonate continuously throughout a long anaesthesia, in spite of other signs of adequate depth.

In using the instrument conditions may arise in the patient which call for the closure of the absorber in order to accumulate carbon dioxide for purposes of stimulation. It is interesting to observe the restoration of blood pressure under these conditions, and the general improvement in vitality in enfeebled cases. The pressure gauge on the instrument gives a remarkable amount of information about the patient after one has become familiar with it. It indicates the fact of clear breathing by its steady movement to and fro on either side of the zero mark. When the absorber is switched on the needle vibrates at either end of its excursion, owing to the passage of the breath past the baffle. If the instrument is level, this disturbance is equal on either side. At normal pressure good breathing imparts a swing of about 10 mm. to the needle, so that one can form an idea of the respiratory vigour under most conditions. If overdose with ether begins to appear the negative side of the excursion representing inspiration will increase and be more active than the expiratory or positive excursion. This corresponds with the jerky inspiration previously referred to.

As regards metabolism, a very good relative idea as to its changes in the course of an anaesthesia is obtained from the visible amount of oxygen required to keep the complexion well coloured. Metabolism inevitably diminishes as an anaesthesia and operation proceed, and, of course, some patients show this more than others. The machine shows it through the pressure gauge. At the beginning of an operation a given supply of oxygen maintains a steady anaesthesia with steady carbon dioxide absorption, but it may be noticed after a little that the pressure of the system is gradually rising. This is due to the fact that in the closed method the oxygen supplied for metabolic purposes is not all being used up by the patient. It collects, and thereby raises the pressure of

the system. On cutting down the supply a little, the pressure returns to the previous reading. The use of ether, with depressing effect on the respiration, frequently shows this rise of pressure in the system. Finally, pressure must rise when the absorbent becomes exhausted or is put out of action for any length of time, but the ball-valve relieves this as previously explained.

Experience with the Closed System

The true criterion of the success or otherwise of any method is the general opinion based on actual experience of the use of that method. My experience of the closed system is based entirely upon the use of the instruments with which I have experimented; it is therefore necessarily limited, and my attitude towards the system may not be quite free from bias. It is unfortunate that experimental conditions do not allow of the distribution of such instruments, even among anaesthetists, in order to get a collective opinion. On this account I have frequently felt the want of collaboration with some of my colleagues, particularly on clinical matters. However, the experience I have gained will, I think, be of interest, and may incline others to turn to this field the attention that is necessary to develop it.

My experience with this machine, and one or two of its less successful predecessors, covers about 350 cases of the usual surgical type. Owing to the convenience of "receiving nights" at hospital for trying out this machine with its innumerable alterations, a great many of the cases were the usual urgent abdominal conditions—appendix, strangulated hernia, perforation of gastric and duodenal ulcers (usually in strong men), and the other odds and ends of a receiving night theatre. The management of such cases very soon showed the capacity of the instrument for dealing with them, and also its limitations.

Positive pressure, one might imagine, would so increase the solubility of nitrous oxide in the blood that its anaesthetic effect would be correspondingly enhanced. This, however, only takes place to a limited degree, merely producing an increased steadiness of the gaseous anaesthesia. Positive pressure does not profoundly deepen the anaesthesia with gas, but let it be used with ether and the strongest man very soon succumbs to its influence. For ordinary work, however, a pressure of 10 mm. is quite sufficient, and this may need to be reduced in some cases. Positive pressure reduces the amount of ether required for muscular relaxation. With this control over ether, it will be understood that difficulty in managing any acute case such as may occur when using an open anaesthetic does not arise, and this is one of the great advantages of the closed system.

Many of the patients were seriously ill, and constituted definite risks with the usual open anaesthetic; with this apparatus, however, they revived, or appeared to do so, on the table under the influence of their own carbon dioxide, which was collected for them by closing the absorber. The stimulated conditions so produced are apt to give a misleading idea as to the patient's true condition, but they may make a desperate operation possible, and so extend the patient's chances of recovery.

Two such cases are of interest in this respect. One was that of a man of 92 with a perforation of a large simple duodenal ulcer. Owing to contraindications to other methods, gas-oxygen was asked for. It so happened that this apparatus with its throat tube was not available at the time; the ordinary apparatus was rendered useless owing to the patient having a profuse beard, and the usual open anaesthetic using some chloroform was resorted to finally. Everything went well with him for the first four days, when his heart began to fail. It was believed that here was a case in which this closed apparatus with its

throat tube would have turned the balance towards a more successful issue. The other case was of a woman of 53, acutely ill from gangrene of part of the small gut. After a rapid anastomosis, ten feet of bowel were removed, and in spite of the usual surgical experience of this condition, the patient survived. It was believed of this case that the patient would not have survived with an open anaesthetic.

The experience of routine surgical cases covers some of considerable length; two, each lasting two and a quarter hours, are notable. One was of a difficult gastrectomy, and the other of an extensive bone graft; both patients did very well. Other cases were of the usual duration—for example, gastro-enterostomies, gall-bladder cases, and the various operations of the lower abdomen, including an abdomino-perineal excision of the rectum. The instrument has also been used for operations on the kidney, breast, and thyroid gland. In toxic cases of the latter, reliance should not be placed entirely upon the anaesthetic, some infiltration being desirable. Nasal operations are successfully dealt with, as the throat tube occludes the pharynx and remains out of the operator's way.

So far as one can see the effects of the method upon the patient are not markedly different from those produced by the other methods. Recovery is quiet and remarkably free from sickness, especially when nembutal is used. It is to be noticed, however, that an opiate as a preliminary drug provides calmer respiratory movements than does the barbiturate, and so may be preferred by some abdominal surgeons. An excessive dose of an opiate should be avoided, for a general anaesthetic may develop its power to a toxic degree, as shown by depressed respiration and sighing, which may last from some hours to two or three days. Such extreme medication is quite suited to the use of spinal and local anaesthetics.

The other aspect of the closed system upon which I may comment is its economics. In this field the closed system is quite supreme. The use of gas-recovery makes it possible to carry out up to thirty cases with 100 gallons of nitrous oxide, as was found when the working costs of the principle were under consideration. Oxygen, of course, is used continuously, but as none can be wasted during anaesthesia on account of the closure of the system, only the smallest amount required for the purposes of metabolism is used. Taking the above thirty cases as generally representing twenty-five hours' anaesthesia, the oxygen required for them amounted to about ten cubic feet. The ether works out at about twelve cases to the pound, but this figure must necessarily vary. The other commodity required is caustic soda. One pound lasts about ten anaesthetic hours, as compared with granular absorbents, which last about half this time.

From these facts there can be no question as to the difference between the recovery principle and the "flow" principle, and with the greater flexibility of the former as a result of the use of the throat tube, a method of using the gaseous anaesthetics is now available which it will be most advantageous to develop.

Conclusion

The advantages of the closed system may be briefly summed up. As a method of using an anaesthetic gas such as nitrous oxide there is some improvement in the steadiness of the anaesthesia, and a little more oxygen is permissible in the average case. One cannot say that the anaesthetic effect of the gas is greatly exalted, even with positive pressure. The need for ether still leaves us with the desire for a more potent gas, and in this connexion we are beginning to hear of one, cyclopropane. The employment of positive pressure is a great advantage, but its use is limited.

X RAYS IN DISEASES OF THE GENITO-URINARY SYSTEM

THE BRITISH
MEDICAL JOURNAL 343

With the closed method less ether is required per case, since to a very great extent it is retained within the system, where it quickly becomes warmed. The use of the throat tube, while making the system workable, assures a clear and adequate airway in any position in which the patient may be placed, and also prevents saliva and other matter from reaching the lower air passages. The anaesthesia is conspicuously dry, even where atropine has been omitted and saliva has flowed profusely. The use of the tube extends the scope of surgery to the head and face, including the teeth. The apparatus used is compact and light, easily handled, and simply constructed. There are no fine adjustments to become deranged. The working costs are the lowest possible, as consumption of anaesthetic gas is independent

of the duration of the anaesthesia, being estimated at so much per case. Where working costs have to be considered, as in most hospitals, the recovery principle provides the usual gas-oxygen anaesthesia for less than the cost of open anaesthetics in cases of average duration. The necessary apparatus and supplies are easily portable.

Reviewing the position as it appears to me from a limited experience of this closed system of anaesthesia, I think we have gained access to a new field of anaesthetic administration sighted by others a long time ago. We must now set about its exploration by developing apparatus and technique, and, with the possibility of finding newer and more potent anaesthetic agents, no one can say what further advantages the closed system has to give.

X-RAY TREATMENT OF DISEASES OF THE GENITO-URINARY SYSTEM*

BY

G. HARRISON ORTON, M.A., M.D.

MEDICAL OFFICER IN CHARGE OF X-RAY DEPARTMENT, ST. MARY'S HOSPITAL

The x-ray treatment of diseases of the genito-urinary system is a somewhat wide subject, and one that cannot be dealt with adequately in the time at my disposal. It is a little difficult to decide where to begin, but it will be well perhaps, in the first instance, to say a few words about technique.

Unit Skin Dose

There is still a good deal of controversy and confusion as to what is implied by a unit skin dose—a skin erythema dose; the number of r units which represent these doses, etc., so many factors, and the grade of erythema produced varying considerably in different clinics. All this is too controversial to enter into in this short communication; nevertheless, it is advisable for me to give some idea of what I am talking about when I refer to an erythema dose. Personally, I mean a dose which, when applied to the skin of the abdomen of an adult, produces a slight redness within three weeks after the application, followed by some bronzing or pigmentation of the skin, but no desquamation. This is at least 25 per cent. less than that often given and described by many as an erythema dose, and may perhaps be described as the mild or minimal.

After some thirty years' experience, however, I have been much impressed by the importance of preserving the integrity of the skin, and would rather limit the skin dose and increase the number of ports of entry wherever possible than run the risk of causing damage. I am well aware that this is not always possible, and there are cases where the dose mentioned may have to be exceeded, but one must be careful not to produce a cure which is worse than the disease, many such having come under my notice. I know that those who advocate a so-called epidermicidal dose say that complete repair takes place; but is this permanent? I doubt it, as most patients so treated do not live long enough to tell the tale. There may be those here, however, who may be able to show that I am wrong.

The dose I have mentioned, if applied at a single sitting, in a certain time, at a certain distance, and at a certain kilovoltage, is a fairly definite one, and is what is implied when I refer to a unit skin dose in this paper; if spread over several days the total exposure required to produce the same effect will be greater. Levitt has stated that a 100 per cent. dose given in one day if spread over

one week would require 150 per cent., and spread over a fortnight some 220 per cent. to produce the same effect. From my own observations I would say that this is a fairly accurate estimate, and important to remember when mapping out a dose that has to be spread over an interval of time. Different diseases require different techniques in order to obtain the best results, and having decided on what is likely to be the most beneficial dose in a certain case, the next thing to consider is the best way to administer it, and we have various techniques to choose from.

Fractional Dose

This is by far the oldest method, and is still largely used, chiefly in the treatment of benign conditions. It consists in giving fractional doses of one-third to four-fifths or so of the unit skin dose at intervals of a few days, a week, or longer, and kept up, in some cases, for a considerable period of time.

Single Massive Dose

This method created a great stir when it was first introduced into this country, and some very exaggerated claims were made for it, which were not substantiated. Its aim is to apply uniformly throughout a malignant growth the largest dose which the tissues will tolerate, the whole dose being given in one day. I tried the method when it was first introduced, in a few cases of malignant prostate, but very quickly abandoned it on account of the practically constant, and often somewhat alarming, constitutional upset which resulted. It still has certain uses, as in the treatment of rodent ulcer, etc., but not, to my mind, in any disease of the genito-urinary system.

Divided or Split Dose

This is a modification of the preceding method. The dose, instead of being given in one day, is spread over an interval of time, at daily or two-day intervals, according to circumstances; and here it must be remembered, as I have already pointed out, that the actual dose given at each exposure will depend upon the time over which the treatment is to be spread. This is the method I consider to be the most suitable in the majority of cases.

Saturation Method

The saturation method is one I have never used. Its aim is, after a maximum dose has been given, to keep up the effect by giving further daily doses of some 15 per cent. of the unit skin dose for several days.

Protracted Fractional Dose Technique (Coutard)

This method is also one of which I have no personal experience. Malignant genital tumours so treated have been reported by Schumacher, who states that although

* Read in opening a discussion in the Section of Radiology and Electrotherapeutics at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

the bladder and intestine have received as much as 2,000 to 2,500 r when this procedure was applied to the lower pelvis, the reaction of these organs was astonishingly little. Possibly our president, who has had some experience of this method in the treatment of cancer of the larynx, may have used it in some genito-urinary case; if so, his experience and that of anyone here who may have tried it will be very interesting.

Various factors which influence the biological effect of a dose of x rays, such as the time taken, the interval between the doses, the quality of ray, etc., are still very controversial, and cannot be entered into in any detail. Generally speaking, it seems to be assumed by most radiologists at the present time that, in the treatment of malignant cases at any rate, the hardest rays possible should be employed—180 kV upwards—and the object aimed at should be to give uniformly throughout a tumour 100 per cent. of the unit skin dose without damage to the surrounding tissues. This, of course, in many situations is extremely difficult, but were it always possible I, personally, doubt if we should find that a cure could be effected—there are so many factors of which, as yet, we know nothing. I could quote quite a large number of cases of breast carcinoma in the early days of x-ray treatment, when a gas tube and 12-inch or 16-inch spark-coil were used, in which recurrences in the region of the scar completely cleared up. Needless to say, the kilovoltage here was nothing like 180; the lesions, true, were superficial, but they disappeared under this type of radiation. I am not one of those who hold that low kilovoltages should be employed in the treatment of malignant disease. Far from it, for various reasons; but I must say that I doubt whether the quality of the ray from high kilovoltage machines is as important as the fact that with such we are able to give a more uniform depth dose.

Another curious fact I have observed on several occasions may be exemplified by quoting two similar cases of bone metastases which came under my care at the same time. In the one the lesion was attacked by giving a unit skin dose through several ports of entry in an attempt to deliver as large a dose as possible; there was no good result—in fact, rather the opposite. In the other, only one erythema dose on the skin over the lesion was given, and the condition completely cleared up, as evidenced by x-ray examinations carried out before and after treatment. How are we to account for this if a 100 per cent. dose is necessary in all cases? And are we not inclined, in these days, to be too mathematical in our dosage, forgetting that the human body is a very variable factor, and that one man's food may be another man's poison? As you know, large doses of x rays are destructive and have an injurious effect upon the patient, the body being able to tolerate only a certain amount of what, for want of a better name, we may call the x-ray poison; small doses, however, have a stimulating effect, as I shall show later. There is one thing I am certain of, and that is that whenever large doses are considered to be necessary they should be so regulated as to avoid, as far as possible, any lowering of the general resistance of the patient, since there is no doubt that many who have received too big a dose go downhill rapidly. Therefore, the ports of entry should be as small as is compatible with efficient radiation; and if on a trial dose there is any upset, the intervals between the doses should be increased from one to two, three, or more days, regulating the dose accordingly, rather than risk this lowering of vitality. It should never be forgotten, as Dr. Gilbert Scott has humorously remarked, that there is a patient attached to the tumour!

Diseases Treated by X Rays

So much, then, for a short survey of general principles. We will now go on to consider the various diseases treated by x-ray therapy, and, in the first place, the kidneys. These organs, situated as they are in the upper abdomen in close relation to the liver, spleen, suprarenal capsules, and large and small intestine, present considerable difficulties, and quite often severe constitutional disturbances are encountered. On this account no attempt should ever be made to give a single massive dose, and the effect of divided ones must be carefully watched, since practically the only conditions radiologists are called upon to treat are growths. There is no doubt that the advance of pyelography and excretion urography has enabled the diagnosis to be made much earlier, such growths as hypernephromata giving a characteristic picture. If an early diagnosis is made x-ray treatment should never be recommended, barring some contraindication, in place of operation; but in advanced inoperable cases such treatment is to be recommended, for although, so far as I am aware, no cure has been reported, there have been cases where a marked reduction in the size of the growth has taken place and been maintained for some considerable time.

Growths of the Bladder

Here again operation is the procedure of choice. The only cases that have come under my care are those where diathermy or operation has failed, or where the growth is considered for some reason or other to be inoperable, and I must say that x-ray treatment in such cases has proved most disappointing. From the experiences published by Sir John Thomson-Walker it would appear that pre-operative radiotherapy, with the idea of reducing the size of the growth, is not to be recommended, as the bladder becomes spasmodic and contracted, and the limits of the growth difficult to define. Neither is immediate post-operative treatment to be recommended when there is an open wound, on account of the risk, a very great one, of increasing urinary infection. In the case of growths unsuitable for operation, or in recurrent growths, x-ray treatment should be tried, and a few good results have been reported, though, as I have said, they are as a rule very disappointing. The split dose method is the one to employ, and the effect of each exposure must be carefully watched; it is advisable, to my mind, to spread the dose over a period of ten days or a fortnight.

Simple Enlargement and Malignant Growths of the Prostate

In my experience simple enlargement of the prostate is very favourably influenced by x-ray treatment, but the results cannot be said to be certain or constant. In view of the fact that in skilled hands the modern operation for enlarged prostate is so successful, I would say that radiotherapy should not be recommended as against operation, unless there is some definite contraindication. Nevertheless, I know of several medical men who, when their own prostate becomes enlarged, preferred to try x-ray therapy rather than submit to operation, and in some cases the results have been most encouraging. One has to remember in these cases that, although the growth is non-malignant, quite a large dose is necessary, in the region of 90 per cent. of the erythema, if the best results are to be obtained. All my cases have been treated through six ports of entry—three anterior and three posterior.

In the case of the malignant prostate the operation is a very severe one, and the results not very encouraging, and in such cases x-ray treatment may be said to compete with surgery. The most usual result of such treatment is, I fear, a temporary improvement with some diminution in size and often reduction of the hardness.

X RAYS IN DISEASES OF THE GENITO-URINARY SYSTEM

THE BRITISH
MEDICAL JOURNAL 345

The latter, however, is not permanent; a relapse usually takes place quite early, but occasionally not for a year or two, or even longer; five years is the longest in my own series. At times, however, one gets a case where the growth appears to disappear completely. In such cases the question of incorrect diagnosis always crops up, but even if the growths are non-malignant, which I doubt, then we have some further proof of the good results in simple enlargement, and the existence of such cases gives ground for hope that with some modification in technique we may find a means of making our numerous temporary improvements permanent.

The bulk of the cases of malignant prostate which have come under my care have been treated by the six field method, sometimes supplemented by a perineal field, the dose being the erythema described on the skin of each area: size of ports, 6×8 cm.; distance, 30 cm.; kilovoltage, 180; filter, $1/2$ mm. zinc or copper + 2 mm. aluminium—the dose being spread over ten days to a fortnight according to circumstances.

In all cases of prostatic enlargement, and the same applies to bladder growths, great care must be taken to reduce urinary infection to a minimum, and if this cannot be done I would say that x -ray treatment is contra-indicated. There is no doubt that urinary infection is accelerated by x -ray exposures, and in not a few cases a general urinary infection following x -ray treatment has been the cause of death. The dose I have mentioned may be repeated after an interval of from six weeks to two months, preferably the latter. It must be pointed out, however, that reaction is generally more marked when a further series of doses is given; therefore the doses should be somewhat reduced and the results carefully watched. All patients should be kept in a nursing home or under medical supervision while the treatment is being carried out, so that any emergency arising from reaction, such as retention of urine, may be promptly dealt with.

Growths of the Testicle

Although some of these are quite radio-sensitive, they should, in my opinion be removed surgically, and x -ray treatment to the glands should follow. The results of such treatment are quite encouraging, and I know of one case where the glands were very definitely enlarged. This was many years ago, and the patient is still perfectly well.

Tuberculous Epididymitis

This condition responds very favourably to quite small doses of x rays, and one patient, treated in 1932, appears to be completely cured after four doses only of $1/2$ B.S.N., 120 kV, 1 mm. aluminium filter, ten days interval between the first and second doses, and three weeks between the third and fourth.

Carcinoma of the Cervix

We will now go on to consider the x -ray treatment of diseases of the female genital organs, and take malignant conditions first. Of these carcinoma of the cervix is by far the most common, and is undoubtedly favourably influenced by x -ray treatment. In quite a fair proportion of cases the disease appears to clear up completely, but here again a recurrence sooner or later, which is much more resistant to radiation treatment, is the rule rather than the exception, though one does occasionally see patients who remain in good health for years after x -ray treatment alone.

A good deal of controversy still exists as to the best form of treatment. There are those who hold that in suitable cases operation in the hands of a skilled surgeon is the procedure of choice; others hold that radium is superior to x -ray therapy; while others hold that a combination of x -ray therapy and radium affords the best

hope of success. At the moment I am against radiation treatment in any malignant condition where an operation can be efficiently carried out, but in cases where, for some reason or another, operation is contraindicated I would say that the combined x -ray and radium treatment offers a better prospect than either given alone. Most frequently at my own hospital radium has been applied in the first instance, and after a suitable interval the patient is sent down for x -ray therapy. I am of opinion that this order should be reversed, radium being applied some six weeks to two months after a thorough irradiation by x rays. I feel that such a procedure would reduce the number of cases in which a recurrence takes place after x -ray treatment alone.

Carcinoma of the Body of the Uterus

On the whole this condition is less favourably influenced by radiation treatment than cervix cases, though quite a number respond quite well. Failing operation for choice I consider that x -ray treatment is superior to radium, and the same applies to sarcoma. The divided dose technique is the best procedure to adopt, though I believe in cervix cases some radiologists still employ the single massive dose as originally worked out at Erlangen.

In the case of the ovary the type of growth met with is very variable, and some growths are undoubtedly radio-sensitive. Nevertheless, if the case is operable I would strongly advise surgical removal, followed by a course of x -ray therapy. In all inoperable cases x -ray treatment is indicated, and, in a few, very remarkable results have been obtained, the patients remaining well many years after. This, however, is the exception rather than the rule, and no doubt the results depend largely on the type of malignancy. It is advisable in all these cases to irradiate the whole pelvis by the divided dose technique.

Non-Malignant Conditions

We now come to certain non-malignant conditions, such as menorrhagias of the menopause, menorrhagias at other periods with no definite pathological condition of the uterus, menorrhagias associated with fibroids, and cases where, owing to dysmenorrhoea or other conditions, sterilization is considered advisable. I have put all these cases together, as the dose in each is practically the same, and may perhaps be called the sterilization dose; it is about 35 per cent. of the erythema dose to each ovary. In this class of case x -ray treatment is, in my experience, most successful, and if we omit certain cases of fibroids we may claim almost 100 per cent. of cures without any undue upset.

Personally, I give a rather larger dose than that mentioned—namely, 40 per cent. through four ports of entry, one anterior and one posterior over each ovary. In very obese subjects this has, at times, been supplemented by a postero-lateral field in each side. Since with efficient apparatus, one-third (or even more) of the dose applied to the skin reaches the ovary, it is evident that these results can be obtained without producing any skin reaction. There are two ways of carrying out this treatment: the total dose may be given at one sitting, in which case it is advisable for the patient to go into a home or to remain in bed for two or three days, or the dose may be reduced to some 25 per cent. and spread over three months at monthly intervals. This causes practically no upset whatever, and the results are excellent in both cases.

I would like to emphasize the importance of having every case thoroughly examined by a gynaecologist before commencing the treatment, and I make it a rule never to undertake a case that has not been so examined, for obvious reasons. As I stated early in this paper, small doses of x rays are stimulating, and this fact may be

made use of in the treatment of cases of sterility with ovarian hypoplasia, in amenorrhoea, and other minor menstrual disturbances. In a series of cases treated at St. Mary's Hospital and elsewhere the procedure has been to give one-tenth of the erythema dose to the skin over each ovary through an anterior port at intervals of one month, and repeated three or at the most four times. The treatment can do no harm, and has proved successful, so far as I can judge at the moment, in a little under 25 per cent. of cases; it is therefore well worth trying. I shall be very interested to hear if anyone present has tried the treatment, and with what results.

There is another minor, but sometimes most distressing, complaint, which frequently responds very favourably to small doses of x rays, and that is pruritus vulvae. A large number of patients get relief, and not a few are cured, but some, for reasons unknown, do not respond at all. My practice has been to give $1\frac{1}{2}$ B.S.N., $1\frac{1}{2}$ to 1 mm. aluminium filter, 120 kV, once a week for three doses, followed by a further dose of $4\frac{1}{5}$ B.S.N. through 3 mm. aluminium some three weeks later. This latter dose I have used also in cases of leucoplakia, but the results, on the whole, have not been very encouraging. Cases of carcinoma of the vulvae referred for radiation treatment are best treated, I think, by radium, followed by a thorough irradiation by x rays of the inguinal glands.

I realize that this communication is incomplete, and deals with the subject in a somewhat scrappy manner, but I hope some points have been raised which will lead to discussion.

THE DIAGNOSIS OF INTRACRANIAL TUMOUR*

BY

HUGH G. GARLAND, M.D. LEEDS, M.R.C.P. LOND.
HONORARY PHYSICIAN, LEEDS PUBLIC DISPENSARY AND HOSPITAL

There is no doubt that many members of the medical profession still consider cerebral tumour to be a rare disease which hardly ever occurs in the ordinary run of general practice, and that its manifestations are obscure and unlikely to be recognized. In fact, however, cerebral tumour is rather common, and gives rise to signs and symptoms which are often easy of interpretation. Although the exact localization of the tumour within the brain may be a matter of considerable difficulty, and indeed it may be impossible, the fact that the cranium does contain a tumour can often be diagnosed at an early stage.

Frequency of Cerebral Tumours

It is always difficult to arrive at a figure which expresses with any accuracy the incidence of a disease in the general population, as there are always so many variable factors which affect such a figure; but in conjunction with Mr. Armitage I have made an attempt to reach some conclusion as to the frequency of cerebral tumour, though these figures are still admittedly open to criticism. We have analysed the records of 13,000 necropsies performed at the General Infirmary at Leeds during the last twenty years, and this series consists of cases of all possible types. We have published a detailed analysis elsewhere,¹ but we were able to draw the following conclusions. There were 3,533 cases in which the brain had been examined (27 per cent.), and of these 264 contained a tumour. Now the brain is examined in any patient who showed cerebral symptoms during life, so that most of the cerebral tumours must have

been discovered; on the other hand, a certain number of symptomless tumours may have been missed. The percentage of brains examined which contained a tumour is 7.45 and the incidence of cerebral tumour in the whole series of 13,000 cases is 2.02 per cent. These figures relate to pathological masses within the skull, and of course a number of these were tuberculomata; the incidence of actual neoplasms is 1.34 per cent. Table I shows the number of cases of cerebral tumour compared with the incidence of other common lesions of the nervous system in the 3,533 cases examined.

TABLE I

Disease Condition	Number of Cases
Purulent meningitis	373
Tuberculous meningitis	356
Cerebral tumour	264
Cerebral haemorrhage	211
Cerebral abscess	165

For the figures contained in Table II I am indebted to Dr. Georgiana Bonser; they are taken from the same series of necropsies. In this table the number of cases of cerebral tumour is compared with the number of cases of other common tumours.

TABLE II

Cancer of colon	26 per cent.
Cancer of stomach	2.5 "
Cancer of lung	1.2 "
Cerebral tumour	2.0 "
Cerebral neoplasm	1.3 "

The conclusion one can draw from this table is that a mass inside the skull is almost as common in the post-mortem room as a cancer of the stomach or of the colon, and that 66 per cent. of these are true neoplasms. These figures, then, give some idea as to the frequency of cerebral tumour, and it is interesting to compare them with some clinical figures from the National Hospital, Queen Square, published by Walshe²: of 1,309 cases admitted in one year cerebral tumour heads the list of classified diseases with 163 examples, disseminated sclerosis being second with 133, and neurosyphilis, of all forms, third with 113.

The third table shows the relative frequency of the different pathological types of tumour compared with similar figures quoted by Walshe,⁴ which refer to cases operated on at the National Hospital and by Cushing at Boston.

TABLE III

Type	Leeds	London	U.S.A.
Glioma	35.9	40.5	41.5
Metastases	11.3	6.4	4.0
Meningioma	5.6	13.5	12.2
Neurofibroma	1.5	11.5	8.5
Pituitary	3.3	13.1	25.2
Tuberculoma	33.8	2.6	2.8

It will be seen that in all cases the glioma is the commonest type of tumour, but the most striking difference between the lists is with regard to the tuberculoma. The reason for this has been pointed out¹; it is because tuberculoma does not give rise to physical signs until it is complicated by tuberculous meningitis, and for this reason practically never reaches the surgeon's hands. It appears that tuberculoma of the brain cannot

* A lecture delivered to the Halifax Division of the British Medical Association, March 15th, 1934.

be diagnosed during life. I do not propose to discuss the other pathological types save to say that there was only one example of gumma, which serves to emphasize how uncommon this condition is.

Symptoms of Increased Pressure

The manifestations of cerebral tumour can be discussed under four headings—namely, those due to increased intracranial pressure, focal symptoms, epilepsy, and mental changes.

With regard to the first group I would like to mention briefly the reasons why a cerebral tumour produces an increase of intracranial pressure. Owing to the skull being rigid the volume of the brain must remain constant, and this volume depends on the mass of the brain, and the volume of the blood and of the cerebro-spinal fluid. The mass of the brain is increased by tumours, but in the slowly growing types this may be very slight. Pressure of a tumour on surrounding veins produces oedema as well as congestion of more distant veins, and, lastly, the circulation of the cerebro-spinal fluid may be obstructed directly—for example, by a tumour compressing the aqueduct of Sylvius. Now the pressure of the cerebro-spinal fluid can be measured very easily by means of a simple graduated glass tube and a lumbar puncture needle. With the patient lying on his side the pressure in a normal person varies from about 80 to 120 mm. of water; this figure, of course, represents the pressure within the skull, and in cases of cerebral tumour it may be 500 mm. or more.

Headache.—The commonest manifestation of increased intracranial pressure is headache, which occurs in nearly 90 per cent. of cases. The headache is paroxysmal in the early stages, being worse when the patient is lying down; it is particularly severe on waking in the morning, and often passes off during the day. The pain is increased by excitement, laughing, coughing, or sneezing, and as the condition advances the headache tends to become continuous. But there are other types of headache seen in cases of cerebral tumour; there may be a localized pain due to pressure of the tumour on the skull, and in this case there may be tenderness on pressure over the site of the pain. In pituitary tumours there is frequently bitemporal headache, and in posterior fossa tumours pain is sometimes referred down the back of the neck, but, on the whole, headache has little localizing value. Headache commencing in adult life which is severe and progressive should arouse suspicion of cerebral tumour, and it may be the patient's only complaint for weeks or months.

Papilloedema.—The next most common manifestation is papilloedema, which is seen in three-quarters of the cases. Papilloedema, which is a true oedema of the disk due to venous obstruction, shows itself as redness, blurring, and eventually swelling and haemorrhages; in the early stages there is little or no impairment of vision, but later the visual acuity diminishes, the visual fields contract, and blindness results unless the pressure is relieved. Papilloedema may start in one eye before the other, but this is of no localizing value. A patient may present himself on account of failing vision, but this is unusual, and by the time vision is impaired there are nearly always other signs and symptoms. Papilloedema is seen in conditions other than cerebral tumour; any cause of increased intracranial pressure will produce it—for example, meningitis or cerebral abscess—and I have seen a high grade of papilloedema develop within two hours of a severe head injury; it occurs, of course, in uraemia and in septicaemia, but the most difficult cases are those associated with arteriosclerosis of the cerebral vessels; in the past two years I have seen six cases with papilloedema associated with gross changes in the retinal vessels and raised blood pressure, but in each there was

a cerebral tumour as well as cerebral arteriosclerosis. One concludes, therefore, that if a patient has marked papilloedema and has no renal disease he is probably suffering from a cerebral tumour whether he be an arteriopath or not.

Vomiting.—The third most common symptom of increased pressure is vomiting, which occurs in some 60 per cent. of cases. Like headache and papilloedema, it may be the only symptom at first, and in this connexion I should like to say that the triad of headache, vomiting, and papilloedema is not seen in complete form in more than half the cases of cerebral tumour. Although vomiting of cerebral origin is said to be projectile and unassociated with nausea this is not true in many adult cases; there may be severe nausea and retching. The vomiting is usually worse in the morning at the time when the headache is most severe. Vomiting occurring in an adult without dyspepsia should always arouse suspicion of cerebral tumour, and if it be associated with headache the diagnosis is almost certain.

Vertigo is a less common symptom of increased pressure; it is usually little more than a feeling of unsteadiness and, though it may be severe in cases of cerebellar tumour, it has little localizing value. There are no changes in the pulse rate, respiration rate, blood pressure, or temperature which are in any way characteristic of increased intracranial pressure, but in the terminal stages the pulse is usually slowed.

Focal Signs of Cerebral Tumour

The second group of manifestations of cerebral tumour consists of the focal signs. In the greater proportion of cases a tumour presents pressure symptoms first and focal symptoms later; sometimes the focal symptoms appear at a very late stage, and sometimes never at all. But in some cases the patient presents himself on account of some disorder which is clearly due to a focal lesion of the brain, such, for example, as progressive hemiplegia, progressive speech defects, defects in the visual fields, or unilateral sensory changes. The exact interpretation of these signs demands a full knowledge of the anatomy and physiology of the brain, and forms too large and complex a subject to discuss here; further, when focal signs are associated with pressure symptoms, certain false localizing signs may appear, and an accurate diagnosis becomes increasingly difficult. But what I wish to emphasize is that when a patient shows evidence of an increasing localized lesion of the brain he is probably suffering from a cerebral tumour, despite the absence of headache, vomiting, and papilloedema. I have recently seen a woman who complained of pain down the left side of the body for many months; there were no symptoms of increased pressure, but she was suffering from a tumour involving the right optic thalamus.

The tumours which present themselves by virtue of their anatomical position more often than any others are, perhaps, the pituitary tumours, so that a word about their manifestations is not out of place. These tumours may produce symptoms either on account of diminished pituitary secretion, less commonly because of over-secretion, or from pressure on surrounding structures; an adenoma of the pituitary gland, unlike tumours arising from the pituitary stalk, rarely produce general pressure symptoms, at least not until the late stages. The changes associated with hypopituitarism are obesity, increasing smoothness of the skin, falling out of the hair, somnolence, fall of blood pressure and of metabolic rate, amenorrhoea, and impotence; any one of these may be the first symptom for which the patient presents himself. In addition, there may be great thirst and polyuria, the condition known as diabetes insipidus, and this again may exist for years as an isolated manifestation. Hyper-

pituitarism exhibits itself as gigantism in the young or as acromegaly in the adult. The type of pituitary dysfunction depends on the histological characters of the tumour, and this does not concern us here, but hypopituitarism is sometimes seen in cases of cerebral tumour remote from the pituitary gland. When there is a marked degree of internal hydrocephalus the third ventricle may be enormously distended; it bulges forwards and downwards, erodes the sella turcica and then compresses the pituitary gland. I have recently seen a case in which a girl complained of headache, failing vision, amenorrhoea, and increasing obesity; she had very large pupils, which were fixed to light, and a high degree of papilloedema; *x* rays showed that the sella had been completely disintegrated. At post-mortem examination the distended third ventricle presented at the base of the brain as a large cyst, which had eroded the walls of the sella. The tumour was a small glioma lying in the corpora quadrigemina.

Then there are the manifestations of pituitary tumour which are produced by local pressure, and the most important of these results from pressure on the optic chiasma; such pressure produces changes in the visual fields, the most usual being bitemporal hemianopia; less commonly homonymous hemianopia may occur; if untreated this condition progresses to complete blindness with optic atrophy. Then the enlarging tumour distends the sella turcica; this can be seen by *x* rays, when the sella is ballooned out, though it preserves its shape. As the tumour expands it may cause expansion of the root of the nose; there is often a complaint of mucous discharge from the nose or of epistaxis, and rarely of cerebro-spinal rhinorrhoea. These, then, are the manifestations of local pressure, and I would particularly emphasize the changes in the visual fields. There is one other common symptom of pituitary tumour, and that is headache; this is not the headache of increased intracranial pressure, and it is usually bitemporal and often very severe.

Epilepsy and Mental Changes

The third way in which a cerebral tumour may present itself is epilepsy. Epileptic fits are common in the late stages, when there is marked increase of pressure. There may be fits of the Jacksonian type when the tumour involves the cortex, such fits being of great localizing value. But perhaps the most important condition is epilepsy which antedates all other symptoms of a tumour for months or years. There is nothing about these fits which serves to differentiate them in any way from what we call "idiopathic" epilepsy, and the underlying tumour may lie in any part of the cerebrum. There have been cases in which epilepsy preceded other symptoms for as much as eighteen years,¹ and Walshe² considers that when epilepsy occurs for the first time in adult life cerebral tumour is the most likely cause of it. I have recently seen an adult epileptic in whom *x* rays revealed a large calcified mass in the substance of the right frontal lobe, almost certainly a tumour of some kind.

And lastly, there may be mental symptoms. A large proportion of cases of cerebral tumour exhibit mental symptoms at some time or other, although the proportion of cases in a mental hospital suffering from a cerebral tumour is small. The commonest cause of mental symptoms is the increased intracranial pressure, but there are cases in which mental symptoms depend on the anatomical position of the tumour, and they may antedate the symptoms of increased pressure. Tumours of the pituitary stalk are often associated with marked apathy and drowsiness, and tumours in the left hemisphere (in right-handed people), producing speech defects, often

show mental changes at an early stage. But the tumours most commonly producing mental changes are those of the frontal lobes and the corpus callosum. The pattern of the mental changes appears to have no localizing value, and the psychotic picture may be of various types. In the late stages, when pressure is much increased, the patient is usually drowsy and apathetic, and this often indicates the beginning of the end. But there may be lack of concentration, failure of attention, indifference, and loss of memory for recent events; sometimes there is incontinence of urine, with regard to which the patient is usually quite indifferent ("mental incontinence"), and this is often seen in cases of frontal tumour; in other cases there may be facetiousness and euphoria, and others may show depression.

Differential Diagnosis

We have to bear in mind that any condition producing a rise of intracranial pressure, or any localized lesion of the brain, may in certain circumstances simulate cerebral tumour. One of the first conditions to consider is renal disease, in which there may be headache, vomiting, and papilloedema, sometimes associated with transient hemiplegia or monoplegia; the diagnosis here depends on examination of the urine, the blood pressure (which is always raised in such a case), and the blood urea. Cerebral abscess does not often give rise to difficulty, as there is usually a history of recent ear disease; an important point to remember is that papilloedema is often absent in cases of cerebral abscess. Hydrocephalus following meningitis should not give rise to difficulty, but sometimes hydrocephalus complicates middle-ear disease; this condition, which is called otitic hydrocephalus,³ is associated with high-grade papilloedema, and is of doubtful origin. Cerebral aneurysm rarely simulates tumour, for the reason that aneurysms are usually small, and only give rise to symptoms when they rupture. Neurosyphilis may simulate tumour in several ways: the early mental symptoms of a tumour sometimes resemble those of G.P.I., and in both epilepsy may occur. As I have already said gumma⁴ is a rare condition, but there was an instance in Leeds recently where a gumma presented as a case of cerebellar tumour. Careful examination of the pupils, combined with serological tests of the blood and cerebro-spinal fluid, should prevent an error in diagnosis. Lastly, cerebral arteriosclerosis unassociated with renal changes produces an infinite variety of clinical pictures which may resemble cerebral tumour, and it is probably the frequency of vascular disease that makes the diagnosis of cerebral tumour much more difficult in middle-aged and older people.

Conclusion

In conclusion, then, cerebral tumour is a common disease which occurs at all ages and produces a variety of signs and symptoms, which may be equivocal in the early stages. But if cerebral tumour be always kept in mind careful examination of the nervous system, together with examination of the cerebro-spinal fluid, will suggest the diagnosis in the great majority of cases; it is very important to make a diagnosis at an early stage, as many types of intracranial tumour are now suitable for surgical treatment, but surgical treatment can never hope to be of much value when there has been great and permanent damage to the brain.

HEADACHE FOLLOWING LUMBAR PUNCTURE

BY

H. W. ALLEN, B.M., B.Ch. OXON, D.P.H.

ASSISTANT MEDICAL OFFICER, V.D. DEPARTMENT, ST. THOMAS'S HOSPITAL

The phrase "Post-punktioneller Meningismus" has been used in the German literature to describe the syndrome that may consist of headache, neck pains, giddiness, tinnitus, nausea, vomiting, and occasionally sphincter disturbances, following, with a certain latent period, lumbar puncture. The word "headache" will be used briefly to connote the above syndrome in this paper.

Historical

Von Quincke¹ introduced lumbar puncture in 1891, and it was soon recognized that headache was an occasional sequel and a definite drawback to its use. In cases of cerebral tumour headache might be succeeded by death, which was apparently the result of a low pressure in the spinal subarachnoid space allowing the high pressure in the cranial cavity to compress the medulla and cerebellum in the foramen magnum. Sicard,² in 1902, first assumed that these phenomena were due to leakage through the hole made in the spinal dura, and he found that rest in a bed with the foot raised obviated headache entirely.

Although the leakage theory is not generally accepted, it is supported by the experiments of Strecker,³ Ingvar,⁴ Weed,⁵ etc. It is well known that withdrawal of large quantities of cerebro-spinal fluid will in itself produce headache, and this, like post-lumbar puncture headache, can be relieved by injection of saline into the spinal canal (Jacobaeus and Frumerie⁶). The latent period before headache, together with an occasionally observed increase of cells in the fluid, have led some writers to postulate an aseptic meningitis at the puncture point. On either theory the use of a thin needle seems indicated, and a

FIG. 1.—Dattner needle ready for use. (Half size.)

FIG. 2.—Dattner needle. Inner cannula pressed forward; stylet of inner cannula removed.

double-cannula needle was advocated by Hoyt; it was first investigated by Antoni⁷ in Sweden, who took spinal fluid from thirty ambulant patients with no consequent headache. Dattner,⁸ using the same needle, found that out of 106 patients giving normal fluids only six suffered severe headache, while out of ninety-four with pathological fluids there were only two instances of it.

Investigation

On Colonel L. W. Harrison's suggestion the writer investigated, with the Dattner lumbar puncture needle, 127 cases of treated syphilis as regards the incidence of headache. This instrument consists of an outer cannula, diameter 1 mm., and an inner cannula, diameter 0.5 mm., the latter being provided with a stylet. The inner cannula may be fixed within the outer by means of a screw. It is of rustless steel, but platinum is possibly a better material for the inner needle. The instrument is made by Messrs. Down Bros.

So far as is known to the writer no similar investigation has hitherto been published in this country.

Note on Technique

The sitting or lateral lying position may be used. The advantage of the former is that, as the result of the higher pressure, the fluid flows relatively easily through the small-bored inner cannula, and thus quickly appears on the removal of the stylet when the subarachnoid space has been reached. A disadvantage is that syncope may interrupt the operation in the sitting position. In order to procure tranquillity in the patient during the entry of the needle local anaesthesia is recommended, but is not essential. The cutting end of the inner cannula should be orientated to separate rather than to transect the fibres of the dura or ligamenta flava.

The outer cannula enters to within a short distance of the dura, the screw fixing it is loosened, and the inner cannula is then pressed forward. If no fluid is obtained on withdrawing the stylet the inner cannula is brought back and the outer further advanced before another attempt is made to pierce the dura. When flow is established a syringe attached to the inner cannula expedites withdrawal of fluid. In cases of obesity, spinal curvature, calcification, or ossification of the ligaments, and where there is possibly some pathological change within the canal, it may be difficult or impossible to perform satisfactory puncture in one space while it is feasible in the space above.

Patients are rested face downwards for twenty minutes after the operation and given analgesics to be used in the unlikely event of headache supervening. In such a circumstance they are instructed to lie down if possible, or to come back to the hospital, where they may receive an injection of 40 c.cm. of distilled water intravenously, as recommended by Brain and Strauss.⁹

Results

The table below shows the results as regards headaches, contrasting two different methods of obtaining cerebro-spinal fluid. It may be noted here that the cell counts of fluid obtained with this needle are quite probably smaller than those obtained with larger-bored needles, for the inside of the inner cannula cannot be properly polished, and cells will tend to adhere to it.

Number of Cases	No Headache	Slight Headache	Severe Headache Causing Loss of Working Time
Using correct puncture with inner cannula:			
25 Pathological fluids	22	3	1
50 Normal fluids	75	15	1
Using incorrect puncture with outer cannula:			
1 Pathological fluid	—	—	1
10 Normal fluids	5	1	4
Total	103	17	7

Indications

The use of the Dattner needle is particularly indicated where fluid has to be obtained for qualitative examination from ambulant patients. Since it takes about ten minutes for fluid to fill the usual manometer, owing to the small bore of the inner cannula, pressure and its changes are not easily registered. The double-cannula needle is recommended by Dattner for cisternal puncture.

DEFECTIVE HEARING AS A NATIONAL PROBLEM*

BY

G. P. CROWDEN, M.Sc., M.R.C.S., L.R.C.P.

LECTURER IN INDUSTRIAL PHYSIOLOGY, LONDON SCHOOL OF HYGIENE
AND TROPICAL MEDICINE

I conceive it to be my duty in this opening paper to make it clear in what respects defective hearing is of national significance, to define the scope of our deliberations, and to indicate, in outline only, the many and varied aspects of the problem which will be dealt with in detail by those who have come here to-day to give to us the knowledge and information they have acquired by special study and experience.

Man is dependent on his special senses for his awareness of his environment and his appreciation of his fellow men, for the possession of sensitive and delicately balanced sense organs linked with the central nervous system enables him to pick up and interpret the varied physical stimuli of the external world, and to react in a way which we describe as normal. If his organs of reception of stimuli are less sensitive than those of his fellows he is at a disadvantage in the struggle for existence, the handicap being particularly severe if the special senses of hearing and vision are involved. Advances in medicine and surgery, the application of physics to the study of defective vision, and the routine inspection and care of the vision of the school child, have reduced the individual and national handicap of visual defects very markedly. The same, however, cannot yet be said of defective hearing, and therefore the Section of Medical Sociology of the British Medical Association is giving this subject special consideration in the hope that the lines of progress towards a solution of the problem will become clear, and that professional and public interest will be aroused to take action for the good of individual sufferers and of the nation as a whole.

At the outset, lest there be any misunderstanding, I must make it quite clear that the special question of the congenitally deaf does not fall within the scope of our deliberations, since this has been given, and is receiving, careful and detailed attention and study by those authorities and individuals who have made it their life-work to help such unfortunate sufferers. It is, however, our duty to concern ourselves with the problems which arise when we consider the incidence, causes, and individual handicap of acquired deafness and defective hearing; to appreciate the grave significance of the problem as a whole to the nation, and to define, if possible, ways and means and methods of prevention and alleviation.

While it has been computed¹ that in Great Britain there are at the present time approximately 40,000 totally deaf, the number of individual adults and children suffering from acquired deafness or defective hearing in one or both ears, and described as the deafened, the partially deaf, or the hard of hearing, is largely a matter of conjecture. We should not, I think, be underestimating the number if we placed it at 2,500,000, for reasons which I hope to make clear when dealing with the question of the detection, assessment, and incidence of defective hearing. It must not be assumed, however, that every man, woman, or child among these two and a half millions is seriously handicapped in everyday life, employment, or education by inability to hear satisfactorily. Many of them have impaired hearing in one ear only; others have such minor degrees of deafness that they themselves do not notice it; while in certain cases—for example, in some noisy trades—it may be a positive advantage to the worker to

be in a measure deaf to noises which cause distress to others with normal hearing. It is true, nevertheless, that a very large number of adults and children are severely handicapped by acquired deafness, which tends to isolate them more and more from their fellows according to the severity of the condition, to hinder them when seeking employment, and, in the case of the child of school and pre-school age, not only to interfere with educational progress, but to retard or prevent the development of normal speech.

It is clear even from this very brief examination of the position of the partially deaf that special problems of social life, education, and employment have to be faced, studied, and dealt with in detail in any comprehensive scheme for the lessening of the handicap to the individual. However, were our deliberations limited to the consideration of the hardship to the individual directly due to impairment of hearing function alone we should fail to see the wood for the trees, and should lose sight of that aspect of the subject which appears to me to be of grave national importance—I refer to the fact that in the majority of cases the cause of defective hearing is disease. In studying acquired deafness we are at once confronted with problems of disease, and in the interests of the health of the nation, therefore, it is essential that the subject should be approached from the points of view of both preventive and curative medicine.

The National Aspect

One has only to consult the statistics that are available for the routine medical inspection of recruits for the Services, and consider the causes of subsequent discharge of men from the Army during training, to become convinced of the seriousness of the present state of the health and physical fitness of the young manhood of the nation, and to have driven home to one's mind the grave significance to health of the widespread incidence of conditions of disease which find their first outward expression in impairment of hearing function in one or both ears. Five years ago I made inquiries into the causes of rejection of recruits for the Army, and consulted the official reports on the health of the Army which are compiled every year by the War Office authorities. It was a matter of some surprise to find that the chief single medical cause of rejection of men applying for service was old and current middle-ear disease. At that time the ratio of rejections per 1,000 men medically examined was 41.38, and the following table, taken from the Report on the Health of the Army for the year 1932, shows that in recent years the ratio of rejections for middle-ear disease, including deafness, has increased to over 50 per 1,000, while these same conditions head the list of causes of discharge within six months of enlistment.

Principal Medical Causes of Rejection and Discharge of Men from the Army during 1931-2 and 1930-1²

Diseases	1931-2		1930-1	
	Ratio per 1,000 Rejected on Examination	Ratio per 1,000 Discharged within Six Months of Enlistment	Ratio per 1,000 Rejected on Examination	Ratio per 1,000 Discharged within Six Months of Enlistment
Diseases of middle-ear (including deafness)	51.20	5.24	53.97	5.53
Defects of lower extremities	41.90	2.46	38.48	2.0
Loss or decay of manvteeth	43.24	2.18	35.04	1.50
Insufficient weight	28.77	0.15	25.57	0.22
Other diseases of heart	27.01	0.90	25.36	0.77
Defective vision	24.26	1.70	21.74	1.50
Valvular disease of heart	18.98	0.68	17.53	0.70
Flat feet	20.81	1.12	15.48	1.08

* Read in opening a discussion in the Section of Medical Sociology at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

The strain of Army training is not great, and, provided the individual is physically fit, the benefit which should be derived from such training is enormous. On the other hand, if some infection is sapping his strength, the recruit will prove unable to profit from the regular life, physical training, and open-air conditions associated with the healthy environment and life of the soldier in peace time; while on active service it has been found that men suffering from middle-ear disease are extremely liable to fall sick. In fact it has been proved to be a bad investment to enroll anyone showing evidence of middle-ear disease or defective hearing, although in civil life even such obvious evidence of infection as discharging ears is apt to be lightly regarded by individuals themselves, and, I regret to say, even by parents.

Reliable figures in respect of the state of physical fitness of the general population are not readily available, and it is therefore very fortunate indeed that the data obtained in the systematic and searching examinations carried out by the Services are published in their annual reports by His Majesty's Stationery Office. In 1928, out of 53,075 applicants for service in the Army, 2,568 were rejected as physically unfit on account of diseases of the middle ear and deafness. In 1932, 54,159 men were examined and 2,993 rejected for the same reason, while a further 290 were discharged as unfit on these grounds within six months of enlistment. It is apparent, therefore, that, even among the young men of the nation, between 5 and 6 per cent. show definite evidence of diseases which are associated with impairment of the hearing mechanism, and that these conditions constitute a major cause of physical disability in the nation.

I have emphasized this, the national aspect of the problem of defective hearing because, in the face of the indisputable evidence quoted from official sources, it is abundantly clear that the subject merits the immediate and closest attention of those who are concerned with the nation's health.

Causes of Defective Hearing

Although disease must be recognized as the principal cause of defective hearing, it must also be borne in mind that cases of material hardship due to acquired deafness without impairment of health are not uncommon among certain classes of industrial workers—for example, boiler-makers, in whom bilateral defective hearing is directly attributable to the nature of their employment. To a lesser degree also accidental injury to the hearing apparatus is a cause of deafness, but unless both ears are damaged the individual handicap is slight, and common experience teaches that in later years all of us must expect a progressive decline in acuity of hearing which, according to the severity of the condition, necessitates correction by appropriate electrical or mechanical aids, the scientific prescription of which is still in a very elementary stage.

From the medical point of view it is the incidence of defective hearing in one or both ears associated with conditions of disease which is significant. In the individual child of school age it is the presence of bilateral defects of hearing of varying degrees of severity which needs special consideration, for, provided the better ear of the child possesses good hearing, the educational handicap is slight. To the sufferer the health aspect is of first importance, but bilateral impairment of hearing function may occasion social hardship. From the point of view of industry the severity of the defect, the impairment of health, and the nature of the individual's employment are factors which determine the handicap to the worker.

Disease, employment, accident, and advancing age are causes of acquired deafness. Each cause and condition

presents its own peculiar problems of prevention, cure, or correction of the defect, or amelioration of personal handicap according to the individual or group of individuals concerned; and while I propose to deal with prevention in respect to the first and second of these causes, I am leaving it for those who follow to consider such subjects as medical treatment and care of partially deaf children, education, the correction of hearing defects, and questions of vocational selection and employment.

Prevention of Deafness Due to Disease

Diseases of the internal and middle ear and pathological conditions of the nose and throat predisposing to infection of the hearing mechanism affect the hearing and health of the individual, and therefore the preservation of both must be the objective of any comprehensive scheme of prevention. While the prevention of the occurrence of these pathological conditions may be a matter of great difficulty, the checking of the progressive impairment of hearing and of health by the early detection and appropriate treatment of cases and potential cases has already proved of value.

Before any steps could be taken in the direction of preventing and limiting the ravages of diseases affecting the hearing mechanism, it was essential to know the common age of onset of the pathological conditions in question, and to have a reliable routine method for the detection of the earliest signs of defect. Consideration of the figures given in the Army reports previously referred to led to an examination of the data published in the annual reports of the Chief Medical Officer of the Board of Education, in order to ascertain if the high incidence of defects of hearing and middle-ear disease in young men was present among children of school age. The returns of the routine inspections of school children appeared to show that this was not the case, for in 1928⁴ the incidence of defects of hearing was 4.2 per 1,000 children examined, and of middle-ear disease 5.4. Even when the defects found in special inspections were taken into account the incidence of these conditions in children of school age appeared to be only one-quarter or one-fifth as great as that found among applicants for service in the Army. Was it possible, therefore, that cases of minor impairment of hearing associated with disease in its early stages were passing unnoticed, for it has long been known that the common infections of childhood are frequently followed by middle-ear disease? A very cursory inquiry revealed the probability that, owing to the difficulty of testing accurately the hearing of school children, ear by ear, in the time available and by the methods then in vogue, it was highly probable that a number of children with minor impairment failed to be detected as needing special examination and treatment by the otologist for conditions of potential disease or actual early disease of the hearing mechanism.

Detection of Defective Hearing by Audiometer

On the occasion of the International Physiological Congress in America in 1929, by the courtesy of the Bell Telephone Research Laboratories in New York, I was given the opportunity of inspecting, and witnessing demonstrations of, various types of audiometers which they had developed, and it appeared that the 4A gramophone audiometer was an ideal instrument for the group testing of children and the detection of early signs of deafness. The American research workers introduced me to their English representatives, the American Telephone and Telegraph Co., and the Western Electric Co. in London, who had had one of these audiometers in their possession for a year or so, and who very kindly loaned the instrument for a preliminary test on children in the borough of Hornsey. It was apparent at once that we

could not obtain satisfactory results with a gramophone record of American speech, and on informing the Western Electric Co. of this they arranged for us to make our own record.

By means of the audiometer, speech sounds of known intensities are delivered to the ear by standardized telephone receivers, forty of which may be linked up without any diminution in the intensity of the sound from each. It is possible, therefore, to test the right ears and left ears of as many as forty children at one time, the record being played once for each ear. There is obviously no opportunity for lip-reading, and as the speech sounds used are numbers, which are written down by the child on a prescribed form, no difficulty of spelling is encountered, and a permanent record is made of what the child has heard. Numbers of two or three digits are used, each figure of which is spoken separately—for example, 526 is heard as five-two-six, and each successive group of digits is stepped down in intensity by a known amount. The level at which the child fails to hear and record the numbers accurately gives a gauge of the acuity of hearing for speech sounds. It is possible easily to test the hearing of 100 children per hour in groups of thirty-two or forty, so that as the whole of a class is dealt with at one time in the space of about 15 to 20 minutes, little disturbance of educational routine is occasioned.

Dr. A. H. Gale collaborated with me in the preliminary survey on the elementary school children in the borough of Hornsey, the results of which were published in the *Medical Officer* for September, 1930.³ That investigation showed that, by means of the gramophone audiometer, not only were all the known cases of hearing defects picked out, but a very large number of children, unknown to have any defect, also failed to pass the hearing test. Subsequent special examination by Dr. Friel showed that in these new cases there existed conditions which needed treatment. In brief, 6.6 per cent. of the children were found to have defects in one or both ears, as compared with 0.42 per cent. shown in the annual returns for the routine medical inspections of elementary school children. It is true to say that a number of these children had very minor impairment, which would pass unnoticed by the ordinary watch tick, whisper, or voice tests, particularly if conducted in the short time available for the individual in the routine medical inspection of school children. None the less, the cause of the impairment could be detected, diagnosed, and appropriately treated with a high probability of restoring the hearing to normal and eradicating the cause before serious damage had been done or a chronic condition had developed.

Subsequent to the initial inquiry in the elementary schools of the borough of Hornsey, further audiometer tests were carried out in the same area, which substantiated the previous findings. An analysis of the results of tests on 1,368 boys and 1,240 girls—2,608 children in all—ranging in age from 7 to 16, revealed a percentage incidence of defective hearing in one or both ears of 6.8.⁴ Independent use of the audiometer by the school medical authorities in the borough of Tottenham,⁵ where 10,000 children have now been tested, and the results of tests in some of the schools of the London County Council all point to the important conclusion that already among children of school age the incidence of defective hearing associated with conditions of disease is as high as that revealed in the medical examination of applicants for service in the Army, and that therefore, to be really effective, measures of prevention must be devised to include children of pre-school age.

From the evidence which has been collected it appears that if the general population of the country were systematically examined for impairment of hearing it

would be found that from 6 to 8 per cent. possess some defect in one or both ears, and that in the majority of cases these defects in young adults or children are directly due to early or chronic conditions of disease. Applying this percentage incidence to the total population of Great Britain, it is apparent that to estimate that two and a half million adults and children have some detectable defect of hearing is not unreasonable. Even if the number were half this figure it would be a formidable task to provide the medical attention which is called for on grounds of the physical disability caused, quite apart from the problems which arise when we consider the lessening of individual handicap.

Prevention of Deafness Due to Employment

It is well known that workers in certain noisy trades—for example, boiler-makers and riveters engaged on ship construction or other work—tend to become deaf, and in a recent investigation for the Industrial Health Research Board⁶ I was able to satisfy myself, by direct observation with the audiometer, that workers of fifteen or more years' standing do tend to develop a bilateral impairment of hearing which in some cases amounts to a material social handicap, though not affecting the man at his job. In employment of this nature, measures for the prevention of defective hearing are not concerned with disease but with the physical characteristics of the environment of the worker at his work; for the continuous noise, the air vibrations, and pressure changes caused by the rhythmic action of the pneumatic tools he uses frequently place too great a strain on the delicate hearing apparatus, with the result that the hearing mechanism ultimately protects itself and the individual by becoming less sensitive to the noises themselves as well as to the sounds which the individual wishes to be able to hear in ordinary life.

Among seventy-six riveters, whose duration of service ranged from about five to forty years, I found thirty-three with defective hearing in both ears. In some of these the impairment for speech sounds was of a severe degree. Among fifty-eight non-riveters, mostly fitters, turners, and machinists at the same shipyard, who had similar lengths of service, only four were found to have bilateral defective hearing. It is clear, therefore, that in the case of riveters we must either protect the hearing apparatus of the individual or control and limit the excessive air vibration and noise in the working environment so that the strain on the hearing mechanism is not too great. In both directions efforts are being made to protect the worker against this cause of deafness—namely, by protecting each ear of the individual by a suitable defender, and using silencers or less noisy tools for the work. Various ear defenders are available, and some of these I have tested under conditions of excessive noise between decks on a boat under construction in H.M. Dockyards at Devonport, and also in the boiler shops of the L.N.E.R. at Stratford. To be of use in practice, any ear stop or defender must be comfortable to wear for long periods. I place this condition first when we consider work in industry, for unless this is the case, however good a defender may be, the worker will naturally not use it if discomfort or pain is caused. Secondly, it must be easily fitted so as to give good protection; and lastly, it must not be costly, for frequent replacement will prove to be necessary. A very simple ear-stop of cotton-wool and wax, devised by W. R. Luxton, my technical assistant, fulfils all these conditions, and judging by the voluntary use of these stops by riveters, holders-up, and rivet boys, and their appreciation of the protection afforded, I feel sure that the workers in excessively noisy trades would derive material benefit from their systematic use.

Conclusions and Routine Measures of Prevention

In planning any general scheme for the prevention of defective hearing there is one fact of outstanding importance which must be borne in mind—namely, that certain conditions of disease arising in early childhood are commonly associated with very minor impairment of hearing function in one or both ears, and that in later life not only may deafness of severe degree develop, but serious injury to health will result if disease in its early stages is left untreated.

Measures of prevention must therefore be effective during pre-school and school age, for it cannot be too strongly emphasized that the evidence which has accumulated during the past five years proves that in a very large proportion of cases minor defects of hearing are among the earliest detectable signs of the existence of pathological conditions, which may, and in fact often do, remain unnoticed unless attention is drawn to them by refined methods of testing hearing and assessing the hearing acuity of each ear of the child in relation to some reliable physiological range or standard of normality.

The investigation on elementary school children in the borough of Hornsey in 1929-30 proved that the first essential step in prevention, the detection of early cases, could be achieved by the routine use of the gramophone audiometer, and enabled a practical scheme for attacking the problem of defective hearing in both its medical and educational aspects to be defined as follows:¹⁰ (1) detection of cases and measurement of defects by audiometer tests; (2) medical examination and diagnosis; (3) medical or surgical treatment; (4) retesting of each case by audiometer to assess the effects of treatment; (5) decision by medical and educational authorities in regard to the subsequent care of the child.

The experience of the school medical authorities in the borough of Tottenham,⁴ where this routine has been followed for the past three years, is most encouraging, for it has proved both possible and practicable not only successfully to treat a very large proportion of cases of early disease, but to restore hearing to normal in many cases in which the defects were severe. If this can be done in one area among a child population of some 25,000, it can be done generally, and is in fact being done in several other areas, and if our discussion to-day results in stirring the public conscience in the interests of the children of the nation, and in enlisting the co-operation of medical, educational, and scientific authorities, it will not be many years before there will be a material decline in the incidence of defective hearing, a lessening of the handicap to the individual sufferer, and an improvement in the health and fitness of the general population.

The University of Durham College of Medicine has arranged a special post-graduate course to be held at the Royal Victoria Infirmary, Newcastle-upon-Tyne, from September 10th to 21st (Saturday and Sunday excluded), from 9.30 a.m. The course includes demonstrations, etc., at the Babies' Hospital, City Hospital, and Princess Mary Maternity Hospital on the Monday, Tuesday, and Thursday afternoons.

Clinical Memoranda

PRESERVATION OF THE UMBILICUS IN THE RADICAL CURE OF UMBILICAL HERNIAS IN CHILDREN

The radical cure of umbilical hernia is very rarely called for in children, in whom the natural tendency to cure is very great. Nevertheless there remain cases which neither undergo a spontaneous cure nor respond to treatment by a truss, and consequently operation is indicated.

It is customary in this operation to make an elliptical incision around the umbilicus and remove it entirely. Such a procedure leaves an abnormal and unsightly abdomen, and in children especially may result in serious psychical symptoms in time to come. The absence of an umbilicus in a child at school must call for comments from other children which are apt to make the child self-conscious, resulting in its avoidance of all forms of sport in which this part of the body is liable to be exposed—for example, bathing, sun-bathing, and so on. This in time may make the child morose and shy, so that it will shun the society of other children, and this may be the origin of a "repression" which affects its entire existence.

The removal of the umbilicus in this operation is entirely unnecessary, and in the words of Victor Bonney—to whom I am indebted for the suggestion to apply it to this condition—"the best surgery is not only efficient, but constructive and artistic as well." When Bonney requires a long abdominal incision he makes it through the umbilicus in the mid-line, re-forming the umbilicus at the conclusion of the operation. I have applied his technique to the treatment of umbilical hernias in children and have found it entirely successful. He tells me that he has used this incision for a great many years, and has applied it to the treatment of umbilical hernias in adults, in whom, I think, it is very desirable, though not of such great importance as in children.

In cases where the umbilicus has been removed at some previous operation, and in which he has to reopen the abdomen, Bonney leaves a little tab of skin on either side, which is turned in to make a new umbilicus. He has not so far described this technique, but it will appear in the new edition of Berkeley and Bonney's book on *Gynaecological Surgery*, which will be published in the autumn.

Spitzzy's operation is designed to save the umbilicus, but I have not found the results so good as when I have followed Bonney's method. This consists in making a vertical incision in the mid-line which traverses the umbilicus, and dissecting the skin off the sac on either side. The sac is then cleared, removed, the peritoneum closed, and the rectus sheath sutured in the usual way. In suturing the skin of the umbilicus the needle is inserted at one edge, it next passes through the fascia in the mid-line, and finally through the skin on the opposite side. When this suture is tied it draws the skin down to the fascia, and as a consequence the depression of the umbilicus is re-formed as shown in the accompanying photograph. If there is redundant skin, some of it may be removed before the sutures are introduced, provided the line of excision follows the natural contour of the skin.

I would like to express my gratitude to Mr. Victor Bonney for prompting me to publish these notes, and I feel that if this technique is more widely practised removal of the umbilicus will come to be regarded as a surgical crime. I am also indebted to Dr. S. N. Varma, house-physician at the Herefordshire General Hospital, for his excellent photograph.

Reviews

LEPROSY

Professor JEANSELME, who was the president of the third International Conference on Leprosy in 1923, has published a sumptuous and comprehensive work, *La Lèpre*,¹ which seems destined to hold for long the first place in the world as an authoritative exposition of the subject. It opens with a very complete historical section with numerous references at the foot of each page, and the author critically examines the evidence and concludes that the oldest known references in the ancient literature of Egypt, Palestine, and India are all open to doubt, but he traces the spread over Europe and the Western Hemisphere from the fourth century B.C. The geographical distribution at the present day is dealt with in an equally comprehensive and up-to-date manner, and the recent knowledge that there are several early unrecognized cases for each typical advanced one is brought out. The next section deals with the leprosy bacillus, and here once more we find recorded all that is best in the literature of this difficult subject, from Hansen's to work that appeared only just before this book, including the evidence regarding the possibility of the existence of a filterable form of the virus. In a similar manner the serology, Wassermann reaction, Rubino's test and the diagnostic reactions of Mitsuda and Bargehr are fully dealt with, together with immunity and allergy. In the section on aetiology the critical acumen of the author is well displayed, and after weighing the evidence on both sides in all disputed questions he is rightly cautious in coming to any definite conclusion on points regarding which proof is still lacking. Thus, he records many examples pointing to infection by inoculation through the skin, but he does not accept any of them as furnishing conclusive evidence that this is the usual mode of infection, and wisely leaves the point open.

The longest section is devoted to a combined anatomical and clinical description of all the stages and forms of leprosy. In this Professor Jeanselme describes and illustrates the particular condition, and then gives its microscopical characters with drawings in the text, mostly taken from the author's own collection, together with fourteen beautiful coloured plates at the end of the work showing both the naked-eye appearances of the patients and the microscopical details of their lesions, commencing with the earliest signs and going on through the macules and the tuberculoid form of Darier to the advanced nodules in the dermal variety, the various lesions of nerve cases, and eye and other complications; the whole constituting a full descriptive atlas of the disease. After dealing with the evolution, prognosis, and diagnosis of leprosy, he describes the prophylactic measures in force in various countries of the world, many of which he has visited in the course of years of investigation. Here once more he gives an impartial survey of a very controversial subject. While he attributes the decline of leprosy in the Middle Ages in part to the rigid and cruel segregation then enforced, and rightly gives credit to the humane Norway system in reducing the disease in Scandinavia, he points out that improved treatment has led to the abandonment of rigid segregation as the one panacea in all countries except Japan, Venezuela, and Colombia, and records the adoption of treatment of early cases at hospitals and dispensaries, and the colony systems in Madagascar and elsewhere.

The section on treatment is equally well balanced, and although the results of the modern injection of chaulmoogra preparations are fully recorded, their limitations

are also brought out, and the place of general hygiene and diet is recognized. In short, this work is a monument of industry and erudition, and should find a place in every library and be indispensable to all serious workers on leprosy, in spite of its necessarily high price.

LEONARD ROGERS.

PULMONARY TUBERCULOSIS

Professor DIETLEN's short textbook on Tuberculosis of the Lungs² gives a well-documented and up-to-date account of the pathological anatomy of the countless forms of pulmonary tuberculosis in human beings, and of the various ways in which the different lesions found arise, or may be thought to arise. The number of the classes into which the patients may be divided is very large, and no doubt, from the point of view of the specialist in pathology and classification, is very satisfactory; the medical practitioner will find little to help him with their diagnosis in Professor Dietlen's pages. A short and generalized account of the treatment of phthisis is given at the end of the book, which is furnished with an index. The volume will be read with interest by all medical men and pathologists concerned with the progress of the theoretical pathology (if one may so call it) of phthisis.

Dr. MARIE's pamphlet on the Gold Treatment of Pulmonary Tuberculosis³ describes the more recent and successful forms of the gold treatment, noting that the claims originally made for sanocrysin (gold sodium thiosulphate) proved later to be excessive. There seem to be no contraindications for the gold cure, which is admirably suited to phthisical patients with pregnancy or diabetes as a complication, with the exception of infancy, cachexia, tuberculous enteritis, albuminuria, jaundice, and a tendency to haemorrhages other than haemoptysis. The gold salts employed are two in number: sanocrysin, given intravenously, and allochrysin (thiopropional sulphionate of gold and sodium), administered by intramuscular injection. With febrile patients the initial dose is of 5 cg.; one injection is given each week, the dose increasing weekly by 5 cg. to a maximum of 50 cg., and in the course of the treatment from 5 to 12 grams of the gold salt are given. If the fever is high two injections may be made each week, the dose being increased as before. In apyretic patients the maximum dose should be 25 cg. of the gold salt. Even with these relatively small doses complications may occur, such as pruritus, erythema, or stomatitis, which demand interruption of the treatment or reduction of the dose; nausea, a transient rise of temperature, abdominal pains, and diarrhoea may also occur, and are in general to be disregarded. Exceptionally such grave complications as oedematous desquamative erythrodermia, acute nephritis, jaundice, and a tendency to haemorrhages may result from the gold treatment. Dr. Marie quotes a number of cases in which the treatment has been successful, and he recommends it strongly to those who are responsible for the treatment of phthisical patients.

In his little book on Intrapleural Pneumolysis⁴ Professor SAYÉ of Barcelona sets out clearly and at length what can be done to increase the scope of the artificial pneumothorax treatment of pulmonary tuberculosis by dealing with the adhesions that so often limit its utility. More than twenty years ago Jacobaeus of Stockholm introduced

¹ *Medizinische Praxis*. Band xvii. *Die Lungentuberkulose*. Von Professor Dr. Hans Dietlen. Dresden and Leipzig: Theodor Steinkopff. (Pp. 141. RM 8; geb., RM 9.)

³ *Pneumolyse Intrapleurale*. Par Louis Sayé. Paris: Masson et Cie. (Pp. 242; 119 figures. 40 fr.)

⁴ *La Lèpre*. Par Ed. Jeanselme. Paris: G. Doin et Cie. 1934. (Pp 680; 259 figures, 14 coloured plates. 600 fr.)

the method of severing these adhesions by the use of the galvano-cautery, and in 1923 recorded 200 cases, with the occurrence of severe haemorrhage in three instances and serious pleural complications in about 11 per cent. of the cases. The method has been improved by Maurer of Davos, and Professor Sayé gives a full account of his own experience in the division of pleural adhesions in patients requiring the artificial pneumothorax treatment, with illustrative skiagrams. He also employs resection of the phrenic nerve and treatment with sanocrysin in suitable cases, with success. The book is well written, and should be in the hands of all surgeons practising the artificial pneumothorax treatment.

In their account of the Reactions of the Tissues of the Lung in Tuberculosis⁵ LEURET and CAUSSIMON describe how the lung acts as an excreting organ in getting rid of foreign bodies or tubercle bacilli brought to it either by the blood stream or the bronchi. The foreign body, whether a grain of lycopodium or a tubercle bacillus, is attacked in the lung by histiocytes and the cells lining the alveoli, and if all goes well is excreted into an alveolus for expectoration. Numerous admirable microphotographs illustrate the authors' argument, which is based on material obtained from experimental animals as well as from human beings.

RESECTION OF THE PROSTATE

In his Endoscopic Resection of the Prostate,⁶ Dr. E. PAPIN summarizes all that it is essential to know on this subject. Omitting any historical references, he begins by considering the anatomy and pathology of obstructions in the region of the bladder neck. The literature has now assumed tremendous proportions, and Papin's simple classification of lesions in this neighbourhood will be extremely helpful to those who have found the pathology of this subject confusing. The instrument he employs is the McCarthy resectoscope. The description of his technique has been considerably shortened by the inclusion of numerous excellent plates showing the resectoscope and the operating theatre with the patient on the operating table. The technique of cystostomy under local anaesthesia is also given, because Papin employs this as a preliminary measure in 25 per cent. of his cases. The mortality table at the end of his work explains this frequent use of suprapubic drainage, since it shows that the chief danger of the operation is sepsis. For anaesthesia he uses the epidural method, injecting 40 c.cm. of 1 in 1,000 percaine. In the majority of cases post-operative treatment consists of tying in a catheter for eight to ten days.

In order to give some indication of the risk of the operation, the author appends various statistics from American clinics. The discrepancy in the figures furnished from these different clinics is considerable, ranging from three deaths in 515 cases to eighteen in 125. In his own clinic he states that he lost three cases out of the first twenty-nine on which he operated, but that in a subsequent thirty there was no death. On the important subject of the indications for perurethral resection he comes to the conclusion that it is the operation of choice for minor enlargement of the prostate, for prostatic bars, and in patients suffering from marked impairment of renal function, cardiac and pulmonary lesions, and diabetes. It may also be used when the patient refuses other operations.

Papin's brochure, which contains only sixty-six pages, provides a masterly summary of this important subject. It is clearly written, well printed, and profusely illustrated.

⁵ *Les Réactions du Tissu Pulmonaire dans la Tuberculose*. Par E. Leuret et J. Caussimon. Paris: Masson et Cie. (Pp. 85; 55 figures. 30 fr.)

⁶ *La Résection Endoscopique de la Prostate*. Par Dr. Ed. Papin. Paris: Gauthier-Villars. 1934. (Pp. 66; 47 figures. 30 fr.)

EXTERNAL DISEASE OF THE EYE

There are few parts of the body where the effects of fatigue and of disease can be observed more readily, with such nicety, and with complete freedom from interference, as in the superficies of the eye and its associated structures. An observer with keen vision, mental and ocular, with or without the aid of suitable magnifiers, has a wide field of structures of the utmost delicacy under view. It is no wonder many have found the external disease of the eye a fascinating study and an opportunity for recording and portraying their observations. The latest and most industrious exponent is Dr. DONALD T. ATKINSON of Texas, whose book, *External Disease of the Eye*,⁷ is a noteworthy production. The title gives a somewhat limited idea of the range of the work, for of the 700 pages some 250 are devoted to the consideration of orbital growths, iritis, cyclitis, glaucoma, cataract, squint, and a variety of operative measures. It is not usual for all these to be embraced within the range of "external disease," though it is true that many of the symptoms of these diseases may be observed without the use of the ophthalmoscope.

The book is written from the personal standpoint, though there are ample references to the observations and researches of others, so that the reader is impressed with the feeling that the author is putting himself into his work with an enthusiasm that is captivating. Further, by means of his artistic skill with brush and modelling wax, he is able to present his impressions in a most vivid manner. We have met with few books so profusely illustrated, albeit some of the reproductions of photographs are somewhat gruesome. The author has given special attention to the various fungus diseases which are so common in the Southern States, and also to ocular manifestations of yaws and leprosy, with which the medical officer in the Pacific Islands must be familiar. Treatment, both medical and surgical, is considered in detail, and there are useful bibliographies. The book is sure to command attention in the United States.

MAN'S FOREBEARS

Although Dr. L. S. B. LEAKEY has named his book *Adam's Ancestors*,⁸ its chief subject is not the origin of man but the origin and evolution of stone cultures. No one has a better right than Dr. Leakey to instruct the public concerning the handiwork of prehistoric man.

Although only just escaped from his "twenties," this author has accomplished more than most men do in a lifetime. He has led three archaeological expeditions to East Africa and made discoveries there of a most surprising nature. Kenya Colony and Tanganyika Territory he found to be richer in deposits of the last period of the earth's history—the pleistocene period—than any other known part of the earth. As the pleistocene period, to which Dr. Leakey gives a duration of a million of years, covers the evolution and differentiation of humanity it is clear that East Africa offers great inducements to those who are in search of remains of early man. Dr. Leakey found evidence of the existence of man in East Africa throughout the whole of the pleistocene period; he discovered stone tools in the oldest as well as in the latest of the deposits of that period which exist in Kenya Colony and Tanganyika Territory. He found not only the stone tools but also fossil fragments of the men who shaped and used those tools. He assigns these fossil fragments

⁷ *External Disease of the Eye*. By Donald T. Atkinson, M.D. London: Henry Kimpton. 1934. (Pp. 704; 479 figures. 35s. net.)

⁸ *Adam's Ancestors. An Up-to-date Outline of What is Known about the Origin of Man*. By L. S. B. Leakey, M.A., Ph.D., F.S.A., F.R.A.I. Foreword by Sir F. Gowland Hopkins. London: Methuen and Co., Ltd. 1934. (Pp. 244; 30 figures; 12 plates. 7s. 6d. net.)

to men of the modern (neanthropic) type, and is of opinion that this type was evolved in Africa. He also holds the view that East Africa was a centre in which various stone cultures found in Europe were invented and elaborated.

Adam's Ancestors throws much light on the early stone cultures of the pleistocene period. Seeing that this period is supposed—and there are valid reasons for the supposition—to have lasted for a million of years, and that already man was a tool-maker at the very beginning of the period, it is clear that the various "cultures" invented and utilized during this long era cannot be grouped under the six or seven simple headings which do duty at the present time. Dr. Leakey shows that under the term "Mousterian" are grouped a series of distinguishable cultures. He deals, too, with the factors which bring about the evolution of new cultures. It is quite clear that the story of man's stone cultures, when fully told—as is certain to be the case some day—will be very long and very elaborate.

In the course of his student days at Cambridge Dr. Leakey prepared himself for his self-appointed task. In the field he continually added to his knowledge, experience, and equipment, so that now he is our leading authority on all that pertains to a scientific search for stone cultures, fossil remains, and prehistoric habitations of man. In this book he places a summary of his methods and of his views before the English-speaking world. The book is just what a young medical man requires—if he wishes to know the latest concerning the history of the evolution of early humanity and the methods which must be learned and adopted if he would join in the search for fossil human bones and crudely worked prehistoric tools.

Notes on Books

The second edition of WHITBY'S *Medical Bacteriology*⁹ only contains a few more pages than the original book, and has the same character and arrangement. The first part, entitled "Descriptive Bacteriology," has proved itself a useful guide for medical students preparing for their examinations, and the second part, dealing with applied bacteriology, has been a convenient source of information for doctors wishing to find out what bacteriological tests can be of assistance in different diseases. A new feature in the present book is a chapter on bacterial variation and its relation to immunity. It is advised that this chapter be omitted by the junior student during a first reading, and not many undergraduates are likely to disregard this warning. More serious students who are settling down to try to fathom the mysteries of flagellar and somatic antigenic structure and haptenes would be grateful for the addition to this chapter of a fairly extensive bibliography or reference to other books in which these questions are considered at greater length. The same criticism might be made of other chapters: without adding much to its bulk the value of the book would have been increased by references to additional reading. However, these are minor points. The great merit of Dr. Whitby's work is that it gives within a moderate compass a clear and reliable account of medical bacteriology, and, in the opinion of many who know it well, it is the best introduction available to the bacteriological section of clinical pathology.

By this time the little book entitled *Parenthood*, by MICHAEL FIELDING, is well known.¹⁰ A third edition has just been issued, and the book has been very carefully revised and somewhat enlarged. It is described as "a manual of birth control," and may be accepted as not only the most popular, but the best presentation and

exposition of the subject from the point of view of those who have no doubts of the propriety, advantage, and general effectiveness of the practice which it advocates. This is frankly the aspect from which the book is written, but it is by no means an extravagant or one-sided statement of the case. As Mr. H. G. WELLS says in a preface: "It gives very clearly and completely, with all the decency of a scientific textbook, exactly what is clearly known and what is not clearly established about preventive methods. It is never vague, sloppy, lyrical, nor shamefaced." There is another side to the question, from the moral standpoint, the strength of which the author does not seem able fully to appreciate; nor does the real danger of under-population appear to be thought worthy of any reference; but if these points are borne in mind, and information upon them sought elsewhere, the reader of this little book should be able to form a reasonable judgement on the subject, and, should he wish to apply this in practice, to do so with clear and reliable knowledge of the methods, successes, and limitations of birth control. The revision has brought the manual fully up to date, and there is an interesting chapter on "Methods of the Future."

In *The Lighter Side of the War*¹¹ Dr. A. CECIL ALFORD gives an account of his varied experience during the period August, 1914, to December, 1918, drawn from diaries and notes taken at the time. He was first in South Africa, and gives an interesting account of the rebellion there in 1914, which tells the reader much that is probably but little known, having been, naturally, so overshadowed by the European debacle. Then in the campaign in German South-West Africa, where he records how a colonel refused to have him as a medical officer because he did not play bridge. After a brief period of training at home he served at Salonika and in Macedonia, where he had an extensive experience of malaria in the Struma Valley, and wrote a book, published in 1919. Finally, he was a short time in France. This record, very frankly written, of personal contacts shows the reactions of an independent civilian to Army routine, and contains many quite fearless comments on men and manners.

Dr. FERRIER'S booklet on *The Cure of Tuberculosis*¹² connects the development of tuberculosis with phosphaturia and with the consumption of acid-producing diets. His treatment is dietetic; the food taken should be largely proteinaceous, and articles of diet that tend to produce acids in the stomach or intestine are not to be allowed. These include milk, fats, fresh fruits, and wine. There should be three meals a day, plenty of water should be drunk, and insoluble calcium salts are advised to combat the decalcification that results from excessive acidity. Dr. Ferrier has found treatment on these lines to be no less efficacious in leprosy.

MISS REYNARD'S *Institutional Management and Accounts*¹³ is a brief guide in matters of finance for the use of managers of residential institutions such as students' hostels, schools, residential clubs, and the like. It shows how the budget should be kept and what the ideals to aim at should be, as judged by the analysis of the accounts of a number of men's and women's hostels of various sizes. The forms in which accounts should be kept are considered at the end of the volume, which is well set up, clearly written, and thoroughly practical. It may be warmly recommended to those for whom it has been written.

The thirteenth edition of *How to Drive a Car* has been published by the Temple Press, Ltd. (2s. 6d.). As the title suggests, this handbook is intended primarily to assist the newcomer to motoring to acquire road sense, together with skill in the handling of a car. Details of how to take particulars after an accident are given, but, more important still, a chapter is devoted to the art of avoiding accidents.

⁹ *Medical Bacteriology, Descriptive and Applied, Including Elementary Helminthology.* By L. E. H. WHITBY, C.V.O., M.A., M.D., F.R.C.P., D.P.H. Second edition. London: J. and A. Churchill, Ltd. 1934. (Pp. 338; 74 figures. 10s. 6d.)
¹⁰ *Parenthood: Design or Accident? A Manual of Birth Control.* By MICHAEL FIELDING. Preface by H. G. Wells. Third edition, revised and enlarged. London: Williams and Norgate, Ltd. 1934. (Pp. 208. 3s. 6d. net; paper cover, 2s.)

¹¹ *The Lighter Side of the War.* By Dr. A. Cecil Alford. London: Hutchinson and Co., Ltd. 1934. (Pp. 290; 17 illustrations. 18s.)
¹² *La Guérison de la Tuberculose.* By Dr. P. Ferrier. Second edition. La Charité-sur-Loire: Robert Thoreau. 1934. (Pp. 125.)
¹³ *Institutional Management and Accounts.* By H. Reynard, M.A. London: Longmans, Green and Co. 1934. (Pp. 31. 5s.)

THE BATHING POOL AND DEAFNESS

BY

A. TUMARKIN, M.B., F.R.C.S.ED., D.L.O.LOND.
HONORARY AURIST, BOZLE GENERAL HOSPITAL

The rush to the swimming pools during the recent heat wave has brought in its wake the inevitable crop of infected ears and sinuses. The public is still unaware of the potential seriousness of these infections, and it behoves us all to stress the importance of prevention as well as of prompt treatment.

From the standpoint of ear infections patients fall into the following groups:

- (a) Those with healthy mid-ears and outer ears.
- (b) Those with a tendency to external otitis.
- (c) Those with old healed otitis media, with or without perforation.
- (d) Those with active middle-ear disease.
- (e) Those with so-called catarrhal mid-ear deafness.

It is highly desirable that bathers should be grouped and advice given to them in accordance with their conditions. Wherever impacted wax is found it should be removed, if necessary after soaking for a few days with guttae No. 1. Keratosis obturans is even more dangerous and obstinate, but perseverance with these softening drops will enable it to be evacuated by gentle syringing, and certainly no bathing can be permitted till the outer ear is quite healthy. In syringing use equal parts of saturated solutions of borax and boric acid, as hot as can comfortably be borne. Hot solutions are far more efficacious than colder ones, and never produce troublesome labyrinth irritations.

The danger of these conditions lies in the fact that, should otitis media occur, it is infinitely more difficult to treat.

Otitis externa has various clinical manifestations, but the commonest is a dry seborrhoeic eczema, commonly associated with a similar condition of the scalp. Treatment should always be in collaboration with a dermatologist. Unfortunately, the patient commonly presents himself after an infection has occurred, with swelling and weeping tissues and possibly even furuncle formation. In general, wetting the ear is to be avoided, but treatment may be instituted with gentle syringing. This should never be repeated unless excessive debris accumulates later. Much the most efficient treatment afterwards is to fill the ear with guttae No. 2 and then pack in ribbon gauze soaked in ung. hyd. ox. flav. This is repeated daily. When the acute condition has subsided a simple spirit and boric drop is useful, or in cases with much pruritus or a tendency to lichenification, guttae No. 3.

Mid-ear infections are, of course, far more serious, and patients with mid-ear disease, active or quiescent, should be made aware of the risks they run. Unfortunately, the practice of plugging the ears is regarded in general as sufficient prophylaxis. I believe this is a dangerous fallacy. Whilst admittedly the entrance of infected water into an unhealthy middle ear via a perforated tympanic membrane is clearly one method of infection, nevertheless I am strongly of the opinion that the commonest method is via the Eustachian tube. In those who dive or swim much under water, but above all in the indifferent swimmers who breathe at the wrong moment, there is always a liability to get a "noseful" as well as a mouthful. A swallowing action then takes place in an effort to inhibit further respiration (the physiologist's "respiration of deglutition"), and the opened Eustachian tube is liable to be flooded with infected water. Further passage

into the mid-ear can occur, more particularly if the tympanic membrane has a perforation to act as a bung-hole. If this is correct, it means that plugging the ears has little value. My own advice to such patients is to avoid diving and under-water swimming. However, if one does get a "noseful" he must on no account swallow or snort or blow. The best plan is to hold the head slightly forward and breathe gently through the widely opened mouth until the nasopharynx has dripped clear.

Patients in group (d) and, to a less extent, group (c) must realize that unless they are exceptionally good swimmers the utmost danger attaches to such strokes as the "trudgeon" or the "crawl." A simple breast stroke is the only one permissible, and actually I always attempt to dissuade them from swimming at all.

The progress and treatment of acute otitis media and its complications are well known, but it is not sufficiently realized that much deafness can occur insidiously as a result of a pathological process quite unaccompanied by the dramatic symptoms of pain, otorrhoea, and so on, and which is therefore allowed to progress unchecked. The underlying cause, I believe, is again the entry of brine into the middle ear. Normally an exudate in the tympanum should be evacuated via the Eustachian tube. Such drainage is very readily impeded by swelling of the mucosa lining the tube, or by interference with ciliary action. We have only to notice the congested eyes of so many bathers to realize what can occur in the much more delicate columnar ciliated epithelium of the middle-ear cleft. If at the same time some brine has become trapped in the tympanum, it will, by its hypertonicity, induce an exosmosis, so filling the ear more or less completely with an aseptic exudate.

Patients with this condition complain of "hearing through cotton wool." They have no pain, or at most an occasional stab or prick, and their temperature is not raised above 99°. On inspection, the drum is quite typical: congestion involving the lower half, distorting the cone of light, but hardly interfering with the appearance of the short process or of Shrapnell's membrane. Occasionally a fluid level is visible and more rarely actual bulging of the lower half of the drum.

Apart from the liability to infection, this condition is of supreme importance in that it aggravates and accelerates all forms of mid-ear deafness, and indeed it is probably the actual initiating factor in many cases. Treatment should clearly be preventive, but we must above all avoid such heroic measures as myringotomy. Of course, if infection occurs the case is treated on the classical lines for acute otitis media; otherwise twenty-four hours in bed in a cool airy bedroom will enable the insulted mucosa to regain normality and to absorb the exudate. The hearing should, however, be carefully tested subsequently, when it will be found only too often that some diminution has occurred. Theoretically one would expect it to show lowering of the upper tone limit, suggestive of round-window lesion, but I have no conclusive findings on this point. Treatment must, of course, be left to a competent aurist.

THE HEALTH SERVICES OF THE NATION
ANNUAL REPORT OF THE MINISTRY OF HEALTH

The annual report of the Ministry of Health¹—not to be confused with that of its Chief Medical Officer—is a matter-of-fact document presenting in their baldest form the manifold activities of a department which is not only the guardian of the public health, but has oversight of the local government in general, and shares with the Home Office the functions of Ministry of the Interior. How varied are the duties which the Ministry is called upon to perform is shown in outline in this report. They include the inspection and supervision of food, measures to deal with water shortage, flood prevention, sewage disposal, public cleansing, the welfare of the blind and of the deaf and dumb, the control of infectious diseases, national health insurance, health education and propaganda, local government finance, relief for distressed areas, town and country planning, and—a matter on which the Ministry has been much criticized during the year—housing and slum clearance.

Official intervention in housing is taken by many people to mean only the erection of new working-class houses in an unending procession. But a very important piece of work by the Ministry, or by the local authorities under its inspiration, is the inspection of existing houses, and action to make them fit for continued habitation. During 1932 one and a half million houses were inspected by local authorities in England and Wales, and as a result of action, formal or informal, by the owners or by the local authorities in their default, 559,000 of them were rendered fit. A prudent use of the powers of local authorities in this respect can prevent the gradual deterioration of houses and the formation of slums, and the Minister urges that inspections for defects should be carried out in a more systematic way. With regard to new houses, the number of houses having a rateable value not exceeding £78 (£105 in London) built since the armistice with State assistance is 1,177,863, and the number built without such assistance is closely parallel—namely, 1,150,522. There seems reason to believe that the Government's reliance upon private enterprise as the main source of supply in the future, as testified by the discontinuance of the housing subsidy, will be justified.

RESULTS OF LOCAL GOVERNMENT ACT, 1929

The most interesting section of this year's report is entitled, "Special Survey of Public Health Services." The Local Government Act, 1929, cloaked under its prosaic title a vast measure of social reform, which is destined to have yet more profound effect upon the public health services as time goes on. Its greatest operation was to abolish boards of guardians and transfer their duties and resources to the councils of counties and county boroughs. Services which could, as a matter of law, be performed by public authorities were thereupon to be separated from the Poor Law; means of co-operation were instituted between local authorities and voluntary hospitals; and, finally, a more active interest by county councils in public health matters was contemplated as a result of the new responsibilities which were placed upon them. The main intention of the Act was to concentrate the medical services of an area in the same hands, not merely to transfer certain functions to the local authorities, but to ensure that those functions, so far as they related to health, were integrated with the already existing public health side of the local authorities' work, especially by the appropriation of transferred institutions as general hospitals or for other public health uses, and by the association of the medical officer of health with the administration of the Poor Law medical services.

As a condition of the payment of block grants from the national exchequer to the local authorities in respect of health services, the Minister is required to satisfy himself that reasonable standards of efficiency and progress are being maintained. As soon as the Act was passed, therefore, general surveys of these services began to be undertaken.

¹ Fifteenth Annual Report of the Ministry of Health, 1933-4. H.M. Stationery Office, 1934. (6s. net.)

taken by the medical officers of the department as the best means of combining the enlarged local responsibility with adequate central supervision. These surveys of counties and county boroughs have now been practically completed, except for London, which is to be reviewed in the next annual report. For the first time, therefore, we have, in the present report, some authoritative general impressions of the early years of a new public health era. The old boards of guardians provided for the sick by a domiciliary service through district medical officers and by institutional services. For the domiciliary service the local authorities have at present no alternative statutory authority, so that it must continue to be provided under Poor Law powers. The most usual arrangement is to employ general practitioners as part-time medical officers, but in some areas the post of district medical officer is combined with that of officer of the institution, and in a few places the service is conducted by whole-time officers. A few authorities have desired, as an experiment, to adopt a panel system, enabling the patient to obtain the services of a doctor of his choice—a method suggested to local authorities by the British Medical Association. During 1933 the Minister sanctioned departures from the Public Assistance Order necessary for this purpose in the case of certain districts in the counties of Kent and Wiltshire and Newcastle-upon-Tyne, and it is stated that several other schemes of an experimental nature are under consideration. A number of local authorities have an open mind as to the most suitable method of administering these services, and the Minister intends to cause some special inquiries to be made by a medical officer of his department into the various methods of working. The surveys, however, have shown that the need for a liaison between the district medical service and the facilities available under other health services of the local authority has been insufficiently appreciated by a number of public bodies; and the Minister hopes that, as a result of representations he has made on the subject, action will be taken to remedy this defect.

APPROPRIATION OF INSTITUTIONS AS GENERAL HOSPITALS

Twenty-seven county borough councils have each appropriated one or two Poor Law infirmaries as general hospitals under the Public Health Acts. In the counties the position is by no means so favourable to early appropriation on a large scale, and up to the present only one county council outside London (Salop) has appropriated a transferred institution as a public health hospital, though it is understood that Middlesex is proposing to take steps with a view to the appropriation of its six Poor Law hospitals within the next two years. Where appropriation has been found practicable the problem of securing full association between the appropriated hospital and the public health work of the council has been greatly simplified. The Minister lays stress upon the need for associating the medical officer of health with the work of the transferred institution, whether appropriated or not. Indeed, the most striking fact which has emerged from the surveys is the predominant importance of the medical officer of health as a factor in the health organization of the local authority. "A capable medical officer of health," says the compiler of the report, "is by far the greatest asset which any health authority can possess." The number of medical officers of health in England, by the way, is 1,149, of whom 401 do not engage in private practice.

As for other medical officers, it appears to the Minister that, with the increasing use of the council hospital for "acute" work, and the increasing realization of the need for careful diagnosis and definite curative treatment, the amount of medical supervision necessary for these hospitals must continue to grow; but in some of them the salary paid to the part-time medical officer presupposes an amount of medical supervision which is inadequate for the proper needs of the hospital. On the subject of co-operation with voluntary hospitals, the Minister states that in some areas the provision for consultation by the local authority with a representative committee of the voluntary hospitals has been regarded as a somewhat unpleasant statutory duty which can

be discharged once and for all by a formal meeting, without any practical measures for consideration. The view of the Minister, however, is that there should be close and continuous co-operation, and a readiness on both sides to regard their respective resources as units in a single hospital service.

Broadly speaking, the surveys do not suggest that in the county boroughs any great or general expansion of accommodation to meet the immediate demands for hospital treatment is urgently required. In the counties, too, taking them generally, the surveys have not disclosed any great evidence of an actual shortage of beds, but there is a considerable amount of accommodation at present used for the sick which is not entirely suitable for the purpose. The need is felt for further institutional provision for advanced cases of tuberculosis, and the beds provided for sanatorium cases are frequently occupied by cases not likely to respond to such treatment. The surveys confirm the view that infant welfare centres have taken their place as an integral part of the health service, and it is also considered gratifying that county borough councils generally have appreciated the importance of including an ante-natal service in their maternity work. During 1933 the number of expectant mothers who attended at ante-natal centres represented 42.2 per cent. of the number of notified births. The number of such centres provided by public authorities in the county boroughs has increased during the last four years from 242 to 281, and by voluntary agencies from fifty-eight to sixty-three, and the number of women attending has grown from 93,000 to 126,000, while in the counties the increase, both in number of clinics and in attendances, is proportionately even more striking.

MATERNAL MORTALITY: INFECTIOUS DISEASES

After all this it is disappointing to find the rate of maternal mortality still advancing. For 1933 the rate per 1,000 live births and stillbirths was 4.32 (being 1.75 for deaths from puerperal sepsis and 2.57 for deaths from other causes). In 1932 the rate was 4.04, and in 1931, 3.94. The infant mortality rate for England and Wales was 64 per 1,000 births, almost the same figure as for 1932, and a little below that for 1931.

A slight diminution is noted in the proportion of the known tuberculous population dealt with under the schemes of the local authorities. An increase in the number of consultations between tuberculosis officers and practitioners is remarked as encouraging. A slight increase in the number of deaths from pulmonary tuberculosis is attributed to the prevalence of influenza during the first quarter of 1933. The number of attendances at treatment centres for venereal diseases continues to increase, the total in 1933 being the highest recorded since the institution of the schemes. The notifications of cases of infectious disease reveal an increase in the prevalence of scarlet fever in the latter part of the year, concurrently with a rather less marked increase in the prevalence of diphtheria. The decline in the incidence of small-pox continued, and in England and Wales only 631 cases were notified during the year, with two deaths. The tables, however, relate only to the calendar year, while the report itself carries the story to March 31st, 1934, and it is recorded that this year has seen the first outbreak of severe small-pox in this country since May, 1929. This occurred at Blackburn in January, where twenty-six persons suffered from the disease, and there were four deaths. There is some ground for suspecting the source of infection in cotton from Egypt. The number of vaccinations expressed as a percentage of total births (38.2) was the lowest recorded, and the declarations of conscientious objection (47.5) the highest.

The Welsh Board of Health, whose report is appended to the main document, comments on the decreasing mortality from pulmonary tuberculosis in Wales. On comparing the years 1931-3 with 1921-3, in only two counties (Brecon and Monmouth) has there been an increase, and in each case only slight, whereas in all the others, and in all the county boroughs, the mortality has decreased, in some areas very largely, as, for example, by 34.6 and 32.6 per cent. in the counties of Cardigan and Carmarthen respectively, and 20.3 per cent. in the

county borough of Swansea. The puerperal mortality rate in Wales was 5.75 per 1,000 births, compared with 5.91 for 1932, but infant mortality swung the other way, being seventy-four as compared with sixty-nine. Midwives attended 93.5 per cent. of the total births registered (73.6 per cent. as midwives and 19.9 per cent. as maternity nurses). It is mentioned that eight authorities in Wales have now made arrangements in their maternity and child welfare schemes for giving advice on contraceptive methods.

CLEAN RECORD OF NATIONAL INSURANCE PRACTICE

The delinquencies of insurance practitioners, of which much has been heard in the past (although they were never considerable when the magnitude of the service is borne in mind) are reaching vanishing-point. A few further figures, as they carry so admirable a moral, may be given. There were in England in 1933 some 15,500 doctors engaged in insurance practice, and the number of insured persons entitled to benefit was over fifteen million. Yet in only seventy-two cases (in the previous year the number was 109) was remuneration withheld on account of transgression, and the amount withheld—namely, £455—compares with £1,015 the previous year. The offence in eight of the cases was negligence, as defined by the regulations; in forty it was failure to keep or return proper records, or furnish required information; in fifteen it was infringement of certification rules; and in six the improper charging of fees. In two cases the doctor was absent from his practice for more than a week without notification, and in one other case there was an irregular issue of both prescriptions and certificates. Only one case came forward during the year on the representation of the insurance committee that the continuance of the practitioner's name on the list would be prejudicial to the service; this case had not been decided when the year ended.

In Wales there is a similar story. The 923 insurance practitioners in the principality accounted between them for no more than twenty-five breaches of the terms of service, for which amounts from £1 to £10 were withheld, and in no case was any representation made as to removal from the list. Similarly with excessive prescribing, just under sixty million prescriptions were issued in England during the year (the increase of 6 per cent. on the year before is attributable to influenza), and the regional medical officers paid 914 visits to doctors whose prescribing appeared to call for explanation, but either the explanation was satisfactory or a hint in time saved proceedings afterwards, for only two cases proceeded to penalty. Another remarkable instance of accord is that in every one of the 990 cases in which the question of range of medical service arose the local medical committee and the insurance committee were in agreement—in forty-nine cases that the service was, and in 941 that it was not, within the scope of medical benefit.

The *International Quarantine Directory*, published by the International Health Office, Paris, is a volume of over 1,000 pages, which contains information from one hundred countries, comprising almost every seaport in the world of any importance. It represents the second edition of the *Quarantine Annual*, which was published in 1930 on a smaller scale, and contains details of the sanitary services of the various ports; the methods ordinarily adopted in the case of arrivals from infected areas; the ports designated to undertake deratization and certification, and the actual work undertaken in this respect; ports which are open to infected ships; and the special arrangements made between individual countries in order to facilitate the working of the International Sanitary Convention of 1926. An English translation of the official French edition of the *Directory* is now obtainable from the Ministry of Health, price one guinea, post free. While it will be of special interest to port sanitary authorities and medical officers, it should also be found useful by shipping companies, masters of ships, and ship surgeons, who will be glad to have information conveniently to hand on port sanitary dues, costs of fumigation, quarantine anchorages, boarding stations, arrangements for medical treatment, and the various other matters relating to the health organization of the various ports at home and abroad.

"CLOSED" ANAESTHESIA

When during the later years of the last century the work of Clover and others demonstrated the markedly increased safety during administration of ether over chloroform, it was the common practice to employ methods which involved rebreathing to a greater or less extent, and this was termed "closed," in contradistinction to "open," anaesthesia. The "closed" method was evolved very largely in connexion with a preliminary nitrous oxide induction; and as oxygen was then seldom, if ever, introduced along with the nitrous oxide, it was always necessary to limit the amount of rebreathing so as to avoid the asphyxial element, and to admit air at frequent intervals into the closed chamber whose contents the patient was respiring. Although at the time the effects of carbon dioxide in stimulating the respiratory centre had not been fully studied by physiologists, in practice this result was attained by accumulation of the patient's own carbon dioxide in the Clover bag, and this partly contributed, in all probability, to the popular esteem which the method attained. In the early years of the twentieth century there was a swing of opinion towards "open" methods of administering ether, in which the rebreathing element was reduced to a minimum, and about the same time the work of Hewitt and many others drew attention to the great value of nitrous oxide with oxygen, which also was usually administered by methods devoid of any intentional rebreathing. Both these popular methods came into favour because they had definite advantages, of which increased safety for the patient was the most obvious and the most important; but they are both rather expensive by reason of the large consumption of ether, or nitrous oxide, or oxygen which is entailed.

In a paper read at the recent Bournemouth meeting of the British Medical Association, and published this week at page 339, Dr. W. B. Primrose sets up a new canon of "closed" anaesthesia, which differs a good deal from the conceptions of Clover's day. His definition draws attention to the economy which results by making the patient inspire over and over again a relatively small quantity of anaesthetic vapour, kept constantly in a life-supporting condition. This proviso is ensured by special treatment of the gases in the closed system, by which the anaesthetic gas is recovered in a state of purity for reinhalation. This would be impossible if in the process of producing anaesthesia the drugs used underwent any change in the metabolism of the patient. As regards ether, nitrous oxide, and oxygen, this is not the case: they are excreted through the lungs unchanged, and can therefore, if collected,

be used over again and so *ad infinitum*. The ingenious apparatus devised by Dr. Primrose for this purpose, and the way in which it is worked, are described in his paper. The description may remind some London anaesthetists of a cartoon which has long adorned the ante-room to the operating theatre of a well-known nursing home, depicting the anaesthetist of the future as a bored technician holding an oil-can in one hand and a lump of cotton-waste in the other, lolling against a complicated engine of dials, cranks, and levers: but actually this machine is of fairly simple construction. It obviously needs scrupulous attention to its working, but will not on that account fail to obtain careful consideration and trial at the hands of those interested in new developments in anaesthesia. In particular, the details of the methods employed to absorb from the closed system as much of the patient's own exhaled carbon dioxide as is deemed desirable by the administrator will receive close attention; and next after that the packing of the pharynx which is necessary to ensure that the "closed" system is really closed. Dr. Primrose realizes what some inventors of new procedures in medicine are apt to forget—namely, that the only just criterion of his method is the results of putting it into practice. He records his own experiences, as far as he has at present got with his researches; and he asks for an extended trial before a verdict is finally passed upon the usefulness of his machine. Clearly, great economy in the use of anaesthetic drugs is one of its advantages, and it is claimed that a greater steadiness of anaesthesia is also attainable. The metabolism of the patient, it is stated, can also be very carefully studied, through changes in the amount of oxygen intake and by watching the pressure gauge: the earliest commencement of overdosage is easily detected.

One passage in the paper raises issues highly interesting in themselves, but requiring much research before an answer can be given. The author notes that "relative overdosage"—a phenomenon long familiar to anaesthetists—which means, in a sentence, that a given saturation of the blood by anaesthetic agent produces a deeper level of anaesthesia in the later than in the earlier stages of an administration, occurs much more noticeably in nervous than in stolid patients. Dr. Primrose believes that in the latter type a larger proportion of the drug used is absorbed into the blood. Here, it would seem, lies ready to be explored a new field for research, if this view turns out after investigation to be well founded. Clearly, if the bloods of different individuals absorb, under similar conditions, differing amounts of vapours supplied to them there must be some physical differences between these bloods. If at the same time it can be shown that the classification of such bloods coincides, even roughly, with a classification of the temperament (which is merely reaction to environment) of the individual, new light might well be thrown both on mental health, on mental disorder, and on haematology. It would be premature and unwise to say more; but a vista for further research is patent to all.

HYPERPITUITARISM AND GRAVES'S DISEASE

The nature of exophthalmic goitre, first observed by Caleb Hillier Parry in 1786 and described by Graves in 1835 and von Basedow in 1840 and by others, has been regarded in various lights ; at first as a cardiac disorder or neurosis, then as an affection of the nervous system, a view endorsed by Grainger Stewart and G. A. Gibson and by Gowers in 1893, the year in which Greenfield gave the first convincing account of the characteristic microscopical changes in the thyroid. The thyroid origin had been previously advocated, especially by Möbius in 1886, and explained as due either to an excess of the normal secretion or to a secretion abnormal in quality (dysthyroidism), a discussion still going on, although there is not any proof of the existence of a thyroid secretion different from the normal. In this century H. S. Plummer has restated the dysthyroidism thesis, and the case against it has been clearly put forward by Harington,¹ who also discussed with scientific caution the rather widespread belief that the histological changes in the thyroid are not primary but the result of some as yet undetermined factor or stimulus. Among the possible underlying causes which have received attention and a considerable amount of experimental investigation are: (1) inadequacy of the adrenal cortex and the resulting loss of inhibitory influence believed to be thus exerted over the activities of the thyroid ; and (2) overactivity of the anterior lobe of the pituitary, and so an excess of the thyroid-stimulating principle called by Max Aron thyreo-stimuline, and now more generally known as the thyrotropic hormone. Experimental injection of an extract of the anterior pituitary has been found to produce in the cells of the thyroid the hyperplasia of the Golgi apparatus characteristic of Graves's disease (Krogh, Lindberg, and Okkels²).

Professor Drouet³ of Nancy has recently published an account of clinical work which points to the conclusions that overactivity of the anterior pituitary is responsible for the changes in the thyroid, and that Graves's disease is a combination of primary hyperpituitarism with secondary hyperthyroidism. It is shown that in a number of cases there was heterogeneous bitemporal restriction of the field of vision which was ascribed to slight pressure exerted by an enlarged pituitary on the optic chiasma. Examination of the urine by Collin and Drouet (1933) revealed the presence of the principle, found in the distal portion as well as in the pars intermedia of the anterior lobe, which contracts the pigment cells of frogs. Diminution of the thyreo-stimuline in the urine of patients with Graves's disease had been previously pointed out by Aron, who suggested that there are two forms of Graves's disease, one solely

due to the thyroid, the other, rare, caused by excessive activity of the anterior pituitary ; Drouet, who contests the validity of such a conclusion, discusses the rationale of a fall in the urinary thyreo-stimuline. In a later paper Etienne and Drouet⁴ lay stress on the persistence, after thyroidectomy, of the contraction of the visual fields and of the urinary reaction for the melanophor-contracting principle. Further, they record the benefit obtained, in four cases, by x-ray treatment alone of the pituitary, not only in the general state but also in special respects, such as a fall in the metabolic rate. The evidence, however, in these articles of structural change in the pituitary in Graves's disease is second-hand, and scanty at that. They recommend treatment of both the pituitary and the thyroid by x rays, and of the thyrotoxicosis by Lugol's solution and hématothyroidine.

Drouet also discusses the neuro-vegetative syndrome, or para-Basedowism, described by Marcel Labbé and his collaborators,⁵ who recognized two constituents in Graves's disease—namely, hyperthyroidism and a neuro-vegetative syndrome which does not respond to remedies potent against hyperthyroidism, but should be treated by sympatholytic drugs, such as the alkaloids of the yohimbin group. This condition may occur spontaneously or follow Graves's disease successfully treated by the established methods, such as thyroidectomy. Drouet, who has found contraction of the visual field and the melanophor-contraction principle in the urine, regards the syndrome as hyperpituitarism without hyperthyroidism. Treatment by x-ray exposures of the pituitary also reduced the blood pressure to normal.⁶

THE STUDY OF ANIMAL LIFE

At a recent educational conference at Oxford it was contended by the opener of a discussion on biology teaching that the dissection of animals by the pupils was an essential part of such instruction ; and the statement was made that " his own boys began cutting up animals as a regular part of the course at the age of 13." He declared truly enough that " biology was a subject which particularly required a practical method of approach. Immediately the teacher began to talk of a nerve, a cell, or a gland he ran the risk of being completely misunderstood unless the student had seen the objects to which the words referred." It may be doubted, however, whether actual dissection by the student himself during the stage of elementary instruction is necessary to this end, and whether demonstration from a dissection otherwise carried out would not be even more effective. Further, it may be argued with very great force that the consideration of anatomical detail is not the best method of approach to the subject ; and that, just as the demand is becoming more insistent that human anatomy should be taught

to medical students largely on the living subject and not mainly on the cadaver, so it should be the behaviour of living things and the relation of their active functions to their structure that should form the foundation of the study of biology. This thesis is not explicitly stated, but is very strongly suggested by Dr. E. S. Russell in *The Behaviour of Animals*.¹ The book is based upon lectures given at University College, London, last year; and its object is stated to be "to interest students and other people in the problems of animal behaviour, and to make clear the principles on which observations should be interpreted." Dr. Russell does not, of course, belittle the need for anatomical knowledge or the value of suitable laboratory experiments, but his main points are two: that it is the careful observation and study of animals in their natural environment which is not to be explained or interpreted as a purely mechanistic or physiological result of a bundle of specific responses to separate stimuli but as arising from the needs of the animal as an entity in relation to situations felt as a whole.

"The animal is regarded as essentially active, not as acted upon, as exhibiting directive activities in relation to its needs and under the guidance of perception, not as an automaton moved this way and that by the direct action of impinging stimuli. . . . The theory that all behaviour can be satisfactorily accounted for as a concatenation of reflexes, conditioned or unconditioned, receives little support from the facts of development. Early behaviour does not arise through the addition and combination of originally separate reflexes. . . . Separate reflexes can be distinguished by analytical artifice, but analysis lets slip the essential thing, the continuity and directness of the action taken as a whole. In the perceptual field, in the same way, we have to recognize a wholeness and unity which is destroyed by physiological analysis."

This point of view and method of approach are set forth with a clarity of statement and a wealth of illustration and reference which make the book not only important in its general thesis, but very helpful as an introduction to its subject.

FUNCTION OF THE SUPERFICIAL OCULAR BLOOD VESSELS

The June and July issues of the *British Journal of Ophthalmology* contain, in two parts, a fifty-six-page illustrated article on "Certain Clinical Features of the Normal Limbus," by Mr. Basil Graves of Bournemouth. The author describes various minute structural features which he has recorded in the past relating to this region of the living eye, the majority of which are only of specialized interest to the ophthalmologist. The article, however, contains an account of certain vascular features which, together with some of the conjectures based on them, may be of much wider interest when considered in conjunction with the fact that the observations were all made on the living human eye. A very detailed account of the capillary blood vessels of the limbus and of the conjunctiva covering the globe is accompanied by various diagrams under a linear magnification ranging from $\times 28$ to $\times 135$. These

¹ *The Behaviour of Animals: An Introduction to its Study*. By E. S. Russell, O.B.E., D.Sc., F.L.S. London: Edward Arnold and Co. (10s. 6d. net)

illustrations show that the "ordered complexity" of the vascular system of the ocular conjunctiva can, in principle, be reduced to multiple long loops springing from the region of both the limbus and the fornix. In the territory between these two sources the loops meet and interdigitate, and here the blood circulation may be seen to hesitate, reverse, or alternate in the direction which it takes in these "zones of equipoise." Each of these loops embodies a fine arterial afferent component—so fine that it can easily be overlooked—in which the blood flow is very rapid, and a coarser efferent channel with relatively dilatory circulation, to which, as the author suggests, the word "venous" should be applied only with reservation: he suggests the term "metabolic vessels" for the efferent components of these loops. At the limbus these long loops have reduced counterparts in the form of shorter and shorter loops—some being so short that they are only stump-like and sessile—accommodated in grooved and crypt-like contours of the basal layer of the surface epithelial cells. The epithelium which separates these conjunctival vessels from the air is only three cells deep, and the author suggests that the vascular system of the conjunctiva has become specialized to form a local primitive superficial "respiratory" mechanism. He mentions an acute affection of the conjunctiva, unrecognized except that it gets labelled "conjunctivitis," and characterized by great dilatation of the metabolic components of the conjunctival vessels, and alludes to a possibility of treating certain surgical and pathological conditions of the eye on the basis of these conjectures. He does not feel that the conjunctival vascular architecture is ideally specialized to facilitate aerial oxygenation of its blood to the fullest capacity, but rather that, among the factors which have contributed to the evolutionary specialization of the design, a partial subservience to this particular function may have contributed to the moulding of the phylogenetic material available. In the interpretation of various features in the conjunctival vessels, the author makes use of observations which he has recorded concerning the behaviour of pathological vascular invasion in the homologous plane of a neighbouring tissue—the cornea—in the course of their living creation. He shows some of the evolutions which vascular afferent-efferent loops undergo in the process of their advance, and, reasoning from these, makes various suggestions as to the correlated significance of features in the normal neighbouring vessels. Thus the arterial and metabolic components of the afferent-efferent conjunctival loops cross one another so frequently in the same relative rotatory sequence as to indicate a significance in this entwined formation, it being suggested that in the course of development these crossings occur when a "reactivation" in the process of advance follows upon a transient lull of the ingressive activity," and it seems probable that a determining factor in the direction of "twist" at these crossings lies in a balance between the two opposed factors of intravascular centrifugal force and the enveloping tissue tension. It is emphasized how the underlying factors influencing many of these simple visible processes are beyond present conception. While the article contains much that is conjectural, the hypotheses put forward are based on precisely defined original clinical observations.

CRYSTALLINE CORTIN

The existence of an active hormone of the suprarenal cortex is now well established, and its presence in any given extract can be more or less accurately standardized on the suprarenalectomized dog. The hormone is essential to life, and if administered in adequate quantities to the suprarenalectomized animal the latter can be kept indefinitely in practically normal health. Deficiency of the cortical hormone is the cause of the series of symptoms associated with Addison's disease, and theoretically the latter should be controllable by replacement therapy. Excess of the active hormone (cortin) may be associated with hyperplasia of the suprarenal cortex or with adenomatous (in some cases adenocarcinomatous) new growth. The series of symptoms due to an excess of cortical hormone is in many respects similar to that found in pituitary basophilism (Cushing)—namely, obesity, hirsutism, weakness, amenorrhoea, and hypertension. The analogy with the various derangements of the thyroid gland thus seems to be complete, definite syndromes being associated with hypofunctioning and hyperfunctioning of the cortical tissue. Surgical measures in cases of hyperfunction or tumour of the suprarenal cortex have met with great success in the hands of certain American surgeons. Replacement therapy in cases of hypofunction of the cortex is complicated by the facts that the amount of active hormone in a single animal (beef) gland is very small, and that the process of extraction is still costly. So much is this the case that, in the opinion of the Mayo Clinic workers¹ in this field, "no method of extraction from the gland will solve the financial aspect of the problem." These workers therefore set out to prepare the hormone in a pure form, to determine its composition and structure, and to prepare it synthetically. Three years' work has led to the crystallization of the hormone. After passing through a period in which they thought that their results indicated that the cortical hormone contained a derivative of adrenaline, the authors established that all traces of adrenaline and its derivatives could be removed from the extracts and the effects upon the survival of adrenalectomized dogs still be retained. They conclude finally, therefore, that the cortical hormone cannot contain adrenaline as a part of its structure. After a series of washings and extractions the active principle can be taken up in ether, then in acetone water, then in water. Traces of xanthine are carefully removed, and the hormone is again taken up in ether. Crystallization is carried out from a water solution to which is added sodium bisulphite and saturated with sulphur dioxide. The crystals appear to have the formula $C_{20}H_{30}O_5$, and its properties point to its being an α -hydroxyaldehyde existing in two forms: a monomolecular form soluble in water and having aldehydic properties, and a polymeric form insoluble in water and not possessing aldehydic properties. The authors find that the compound thus obtained will keep suprarenalectomized animals in normal condition, and that the composition is constant, so that they were not dealing with an adsorption compound. Both forms of the hormone appear to have the same physiological activity. It thus

appears that we are not far from the realization of the task set themselves by these authors—namely, the identification of the structure of the hormone and its synthesis.

THE TREATMENT OF FRACTURES IN THE NEWBORN

At a recent meeting of the Section for the Study of Disease in Children of the Royal Society of Medicine, Drs. Eric Pritchard and Jean Smith presented a paper, now printed in the *Proceedings*,¹ which contains some unorthodox views on the treatment of fractures of the long bones in newborn infants. The authors' interest in the matter was aroused by the example of an infant in whom there were more than a dozen fractures, involving the ribs and limbs, where surgical methods of splinting were clearly inapplicable, and yet at the age of 18 months, following entire liberty of movement and general hygienic measures only, with special addition of vitamin D and calcium, there was apparently complete cure, so that no evidence of bony disease was to be discovered clinically or radiologically. As a result of this experience several infants with fracture of the femur have now been treated on similar lines and carefully followed by x-ray examination. Usually showing severe degrees of deformity at first, skiagrams have demonstrated the throwing out of abundant callus followed by a straightening of the bone and the gradual appearance of a united, perfectly straight femur without any obvious shortening. In the cases recorded crawling and walking have occurred at the normal expected age, and in a cinematograph film, shown at the meeting referred to above, a child of 18 months was seen walking about actively without any limp. As was pointed out on this occasion Nature has been healing fractures ever since the appearance of man on this planet, and the tissue culture experiments demonstrated in Dr. Ronald Canti's now famous film, include one striking illustration of how a piece of cartilage, taken from an embryo chick, will develop into a perfectly shaped bone under proper nutritive conditions. Dr. Pritchard's essential point is that perfect anatomical reduction is not necessary for complete functional recovery, and the restraint imposed upon the infant by complicated apparatus leads to such restrictions of liberty of movement that nervous irritability and possibly secondary nutritional disturbances may easily follow. The traditional method of dealing with neonatal fracture of the femur is to bandage the thigh up against the abdomen in the "foetal" position. Nursing becomes very complicated in these circumstances, and it is doubtful whether much is to be gained by the use of the body as a splint. The application of plaster-of-Paris splints to a rapidly growing baby also presents practical difficulties, and if, as is claimed by Dr. Pritchard and Dr. Jean Smith, entire liberty of movement is not followed by shortening, then there seems nothing in favour of retentive apparatus. This is the crux of the matter, and there were certainly some surgical doubts expressed at the meeting on this point. One of the illustrations in the published paper (Fig. 6) would seem to bear this out, but the clinical observers maintain that no shortening is present, nor is there any

¹ *Proc. Roy. Soc. Med.*, May, 1934, p. 835.

limp. The method certainly has the merit of simplicity, and is worthy of more extended trial. Careful x-ray control, however, is essential, or the practitioner lays himself open to an obvious action for negligence in which orthodox surgical evidence might possibly triumph over Dr. Eric Pritchard's appearance as an expert witness for the defence!

EFFECTS OF X RAYS ON THE LUNGS

Medical literature contains records of many cases in which the lungs of human beings have been injured by long exposure to the action of x rays, conditions such as pleurisy, pneumonia, "Roentgen pleuropneumonitis," and fibrosis of the lung being among those recorded. Engelstad¹ has recently investigated the action of x rays in different doses on the lungs of rabbits, and describes in detail the analogous lesions produced thereby. He finds that doses that do no or but slight injury to the skin usually leave the lungs almost unaffected. Doses causing inflammation of the skin lasting up to six weeks produce grave and often fatal disorders in the lungs, such as bronchitis, bronchopneumonia, generalized inflammatory changes, the production of cartilage, and fibrosis, and these may not all have come to an end six months after the exposure to the x rays. Still larger doses often produce pneumonia, which may be rapidly fatal or may result in extensive fibrosis. Full histological details of the pulmonary changes are given, and they are illustrated by a number of excellent microphotographs. The pleura is more resistant than the pulmonary tissue, and Engelstad finds that fractionation of the dose lessens the injury done to the lungs.

A TREATMENT OF HAEMOPTYSIS

Haemoptysis in pulmonary tuberculosis may broadly be classified into three types. Associated with an early exudative lesion, and loosely said to be due to capillary congestion, it is often fairly copious, generally single, and never fatal. Caseous lesions causing ulceration of small vessels frequently produce small haemoptyses which are sometimes repeated, and, also, never directly fatal. On the other hand, bleeding arising from the aneurysms of unsupported vessels in cavities are copious, repeated, and not uncommonly lead to death. In all cases, however, the symptom is alarming, injurious to the general condition of the patient, and, particularly in the last group, dangerous because of possible dissemination of the disease. Drugs have little or no effect on haemoptysis, and an artificial pneumothorax may be impracticable owing to bilaterality of disease, to difficulty in determining the side of bleeding, or to the presence of adhesions. Moreover, rigid walls of a cavity may fail to collapse. In a recent article Courcoux² describes a method of treatment based on a case reported by Ravana, Benzaquen, and Bibas,³ who obtained arrest of a repeated and very copious haemoptysis after causing extensive subcutaneous emphysema of the chest following failure to induce

an artificial pneumothorax. Courcoux has treated thirty-four successive cases of haemoptysis by injecting 300 to 600 c.cm. of oxygen in a single dose under the skin of the thorax, preferably on the same side as the source of the bleeding—if known. In twenty-five patients the haemoptysis, "often abundant," ceased "immediately and definitely" without recourse to any other form of treatment. In six the injections had to be repeated on several consecutive days in order to obtain a result. The bleeding was unchecked in seven patients (the figures do not appear to tally). The injections, which may be carried out by means of an artificial pneumothorax apparatus, are said to be well supported by the patients, in whom, even when they are ineffective in arresting the bleeding, anxiety is relieved and a "state of euphoria" may even be produced. The method was most efficacious in recent progressive lesions (*poussées évolutives*). No theory is brought forward to account for the beneficial effect, which appears to be found only in those cases in which one would expect the haemoptysis to be in any event a self-limited single episode. It is instructive to note that Pierre-Bourgeois⁴ claims, on the basis of a total of five cases treated, to have obtained equally good results by injecting the oxygen subcutaneously in the thigh.

THE EDUCATIONAL NUMBER 1934

Our next issue, dated September 1st, will be the annual Educational Number of the *British Medical Journal*. Its contents, as in previous years, will include a full account of the requirements of the General Medical Council and of the universities and other licensing bodies in Great Britain and Ireland, as well as information about the opportunities offered by the various medical schools and other teaching institutions, and the fees charged by each. The details given have been revised and brought up to date by the authorities concerned. These sections, the object of which is to furnish a handy guide to intending students of medicine, are supplemented by articles intended for newly qualified practitioners on such matters as post-graduation study in Great Britain, the public medical services, tropical medicine, psychological medicine, and the various special diplomas. The opening article for this year's Educational Number is by Sir Henry Brackenbury; it is entitled "The Training of the Medical Practitioner."

The King has renominated Sir George Newman to be a member of the General Medical Council for five years from October 9th, 1934.

The Harveian Oration will be delivered on Thursday, October 18th, at 4 p.m., before the Royal College of Physicians of London, by Dr. James Collier, whose subject is, "Inventions, and the Outlook in Neurology."

As we go to press we learn that Professor G. Grey Turner, professor of surgery at the University of Durham, has been appointed to the university chair of surgery at the British Post-Graduate Medical School at Hammersmith.

HEALTHY LONDON CHILDREN

HEALTHY LONDON CHILDREN

THE L.C.C. REPORT

London is a problem of the first magnitude. Nowhere is there such an aggregation of people; nowhere are there such problems in health; and nowhere might mistakes or sins of omission be fraught with such disastrous consequences. The report of the School Medical Officer for London, Sir Frederick Menzies, shows what is being done for the betterment of the health of the host of children who are being trained in the numerous schools. The report is a record of almost unbroken successes in every department of school activity. There is no page in it that is not a condensed account of strenuous endeavour and achievement. To the Council and its small army of doctors the work is a great credit, only measurable by those who know what the conditions were among children of these schools thirty years ago. It is convincing evidence of the good that can be done by the earnest, thoughtful, and continuous application of scientific health methods.

PERIODIC EXAMINATIONS

There are some 380 doctors and ninety-seven dentists engaged in the work, many of whom are specialists in their own departments. The work needs to be highly organized and, at the same time, elastic and human, and the association of voluntary agencies is found to be of the highest benefit in this regard. Under the Education Act local authorities must make provision for the medical examination of children at entrance to school, and at such other time as the Board of Education prescribes. Thus there is a routine examination at the ages of 8 and 11. In London there is a further examination in the term before the children leave school. More than 80 per cent. of all children are examined each year. The Council finds there are some disadvantages in the year ages selected, and it is experimenting with examinations at the ages of 7 and 11. Refusals on the part of parents to allow their children to be examined are so few as to be negligible; there were only seventy-five such last year, and of these independent medical reports were obtained in the cases of twelve children.

NUTRITION AND CLEANLINESS

Unremitting attention has been given to the state of nutrition of the children. The long-continued depression with its attendant unemployment has produced acute anxiety lest the children should suffer. A special inquiry was made of 10-year-old children in schools selected as likely to be those where influences of malnutrition might be manifest. In this group 93.5 per cent. were considered well nourished and 6.5 per cent. poorly nourished. The work was undertaken by a skilled observer, and his findings in this *ad hoc* examination compare very well with the results of general medical inspection.

The general examinations have revealed an excellent maintenance of the high standard of cleanliness. Dirty heads are few, and body vermin are found in only one in a thousand. While bad clothing and bad footwear are distinctly less frequent than formerly, there has been a transfer from the "good" column to the "fair" column of from 1 to 8 per cent. The indications from this survey are that while indigence has been alleviated, things are "tighter" among those above the poverty line, and clothing has suffered to some extent in order to provide sufficient food.

The year was one of overflowing sun; this, no doubt, contributed to the healthy state of the children. Fewer defects than ever before were reported. Further, the last has been seen, so far as the elementary schools are concerned of the weakly children of the war.

N. 3084 London County Council Annual Report of the
C. 1933 Vol. III (Part II), Public Health. Report for the
Year 1933 of the School Medical Officer. London. P. S. King and
Sons (18 6d)

DENTAL CARE

There has been a slight falling off in the number of children brought for dental treatment, and this despite the excellent propaganda work of the Dental Board's demonstrations in the schools, which are highly appreciated. A new experimental dental centre has been established in an East End school financed by the Manor Charitable Trust. The work is mainly prophylactic and conservative; no general anaesthetics are used. The idea of the Trust is to demonstrate that the most efficient and economical method of dealing with the problem of dental treatment is to form a small clinic at each school, where most of the children can be dealt with on the spot. By such means a complete oversight of the whole school with a healthy condition of the mouths is obtained. But even this scheme has not overcome the apathy of the parents and the repugnance of the children to the dental chair!

CHRONIC INVALIDITY

The school attendance department reports each month the names of children who have been absent from school for three months or more on account of illness. The number absent on account of rheumatism, chorea, and heart disease still forms a very high proportion of the total, and proves how largely this group of diseases is responsible for ill-health in childhood, especially among girls. On account of the greater incidence of the rheumatic disease among girls (386 as against 222 boys), the total invalidity of girls to boys is 1,007 to 813. Ringworm, formerly the chief cause of prolonged absence from school, accounts for four cases only, compared with 129 in 1919. This is due to the success of x-ray treatment.

EPIDEMICS

Scarlet fever was epidemic in London during the latter half of the year, and this is reflected in the number of cases (11,357) reported. At one centre a number of cases occurred after operation for tonsils and adenoids, despite every care exercised by the staff. Thereafter the children were immunized against streptococcal infection and diphtheria before operation, and no cases either of scarlet fever or of diphtheria have been reported since this procedure was inaugurated.

There were 531 cases of small-pox notified in London in the year, of which 170 were in school children. All cases occurred among unvaccinated children. Facilities for vaccination on the school premises were granted whenever applications were received, and, at the written request of the parents, about 400 children in four schools were vaccinated. The special arrangement, which has now been in force for some years, whereby home contacts of small-pox are allowed to attend school if in a healthy condition has been continued; contacts are kept under daily supervision.

DIETARY OF BOARDING SCHOOLS

An important section of the report deals with the dietary of children in residential schools and homes. The diet was altered in 1932, and superintendents and medical officers were asked for criticisms after a trial of eighteen months. There were practically no adverse criticisms, but complete unanimity in praise of the diet as a whole. Suggestions for slight alterations were made and adopted. The medical officers all remarked on the improved condition of the children, and the absence of skin eruptions, which used to be so prevalent in Poor Law homes, was especially noted. This is important, as unhealthy skin conditions are associated with a diet which, though ample in bulk, is deficient in quality. One of the Council's consultants made a special investigation into physique, and observed the general improvement in stature during the past year as being especially gratifying, since the children as a whole appeared formerly to be stunted in growth compared with normal children. Full details of the "Standard Dietary Tables" are given in the report.

HOSPITALS AND COUNCIL

Special note is made on the arrangements of the school service. It is said that the general care of the children in the London elementary schools is carried on by a social service, consisting of voluntary workers organized in school care committees, assisted and directed by paid organizers. This system prevents the work of medical inspection and treatment and the wider work of general physical care of the child becoming stereotyped and bureaucratized, a fault which might otherwise be difficult to avoid. Friendliness and co-operation with the parents are the keynotes of this service. The teachers, whenever possible, give much assistance, and in many cases it is entirely owing to their help and devotion that the care committee work in the schools is possible.

London is abundantly rich in voluntary hospitals which provide extensive services for the poor, and it has been the aim of the school medical service to work in co-operation with these. In a number of hospitals a member of the Council's Care Committee attends regularly and keeps the hospital in touch with the social services of the schools. This association makes a great difference in the results of hospital treatment.

A warning is attached to the report. Great national disturbances have effects which are both immediate and remote. The remote effects of the war on children born during that period are known. Similarly, though the immediate effects of the prolonged depression appear from a consideration of the massed statistics to be surprisingly satisfactory in comparison with what might have been expected, yet there may have been some undermining of the health of the children which will show itself in insidious ways in the future.

PORT SANITATION AND COMMON SENSE

BY A SHIP SURGEON

It is generally agreed that in no sphere of human activity is tradition stronger than on the sea. Sailors are everywhere, and rightly, regarded as ultra-conservative beings who cling to old-established ways and customs, and are very slow to adopt new ways of doing things. This attitude of the seafarer has affected those who control him, resulting in the continuation of methods which, it is the purpose of this article to show, are now obsolete.

This obsolescence is particularly marked in the health aspect of ships and ports. Consider first the present basis of port sanitation in regard to an in-coming ship—the bill of health. One can well understand the need for this in earlier times, when means of communication were slow, and ships might visit ports subject to no sanitary control. Nowadays, with almost instantaneous spread of news regarding epidemics, and with universal isolation of infectious diseases, the bill of health, with its archaic phraseology, is surely out of date. Nor is it a case of one bill of health. Take the case of a ship proceeding from Liverpool to Palma (Balearic Islands), calling at Gibraltar en route.

THE BILL OF HEALTH

A British bill of health must be obtained at Liverpool certifying that "Whereas the ship — is about to proceed over-seas . . . know ye that the plague, cholera, or yellow fever does not prevail in this port, etc." This must be endorsed (for a consideration to his Government) by the Spanish Consul at Liverpool. At Gibraltar another British bill of health must be obtained, and also a Spanish one, issued by the Spanish Consul at Gibraltar, who presumably has knowledge of Gibraltar's public health inaccessible to the British authorities. Moreover, the Spanish Consul must endorse (again for a consideration to his Government) the British bill of health. From this it will be seen that one arrives at Palma with quite a sheaf of much-vised and stamped documents

(hardly looked at, by the way, by the authorities), and all this so, that a few healthy innocent passengers may disembark and a few others may have a look round the town. The reader will easily imagine how this process multiplies on itself with visits to further ports. As a source of revenue to the countries concerned it may be valuable; as a method of port—and ship—hygiene I maintain it is cumbersome and anachronistic in the extreme. Indeed, I have never been able to see the object of a bill of health at all, save as a possible reflection on the public health authorities of a port. Suppose plague or cholera *did* prevail in Liverpool. Surely the said authorities would take immediate steps to isolate cases and confine the outbreak sufficiently to prevent ships' crews running any appreciable risk of infection. In any case, what large port is there in the world which has not a permanent isolation hospital containing, it may be, cases of typhoid, small-pox, or other infectious diseases? But no ship is thereby prevented from entering or leaving such a port.

One can envisage here a new system altogether. Medical science knows no frontiers, and small-pox or plague is the same disease at Singapore or Southampton, Bombay or Birkenhead. The Health Organization of the League of Nations, or perhaps preferably the Office International d'Hygiène Publique, placing health officers in every large port of the world, might issue a sanitation card to each ship at its original port of departure, the sanitary condition of each port subsequently visited to be stated thereon by the respective health officer. This may be a Utopian ideal, but it is not beyond the bounds of possibility. By international agreement an excellent system now prevails whereby a seaman suffering from venereal disease can continue his course of treatment by applying at the various clinics established for this purpose in all large ports, the details of each treatment being marked on a card supplied to the seaman and presented by him at each clinic.

SHIP HYGIENE

Consider now the question of ship hygiene. By long-established custom a ship is still regarded as an infectious thing, either potentially or actually so. This feeling is particularly strong among the Latin races, perhaps for reasons not unconnected with the personal habits of their nationals. A glance at the form to be filled up at any Mediterranean port (for example, Marseilles) will show this. It refers to disinfection of cabins, disposal of the effects of sick persons, deaths, and coffins. To Latin eyes, too, all illnesses occurring in a ship appear as infectious disease, an extraordinary attitude which rises to its height in South American ports. I have seen a port doctor at Rio de Janeiro hesitate to come on board on being told that one passenger on board was "seek." Apart from the absurdity of this behaviour, it is a sad commentary on local medical ethics. It is incredible that any British doctor would hesitate to enter a house on the ground of its containing infectious disease.

If ships are such dangerous potential carriers of disease, why, may I ask, is no attention paid to trains and aeroplanes? The Orient Express, on its return journey from Constantinople to Calais, passes through many countries on its way, yet no sanitary control whatever is exercised over the passengers, the staff, or the train itself. It certainly does not obtain a bill of health on leaving Constantinople, hardly to be described, I think, as a very salubrious city, certainly no cleaner than Liverpool. A person, too, sickening for small-pox or yellow fever might well travel from the East to this country by aeroplane; yet, so far as I know, no sanitary control is exercised over aeroplane passengers either.

Surely it is time this absurd attitude towards ships and their inhabitants was dropped. The days are now long past when, as a matter of course, a ship returned from an oversea voyage with half or more of the crew dead or dying from scurvy, plague, or small-pox. A modern ship is an eminently hygienic affair, with her regular inspections of quarters and crew by commander and medical officer, her constant washings and cleansings, her exposure to the

AUG. 25, 1934]

ACCIDENTS IN SEWERS

antiseptic action of sunshine and ozone, her periodic fumigations of holds, etc. Indeed, she is a much more hygienic affair than many a house is ashore. Moreover, it should be remembered that sailors spend by far the greater part of their lives in ships. It follows that they are liable to almost any of the diseases found in general practice ashore, and that they may occasionally die of one of these, of pneumonia, heart failure, typhoid, or some serious accident.

PORT AUTHORITY AND SHIP SURGEON

May I then plead for a somewhat more common-sense attitude on the part of port sanitary authorities (especially foreign ones) to such illnesses (and possibly, deaths)? After all, the surgeon on board knows at least the fundamentals of his job; indeed, in these days of enhanced status and increased pay for ship surgeons, as like as not he will be found to be highly efficient and trustworthy. (The day of the old-time ship surgeon, rarely sober, whose main duty on board seems to have been that of jester and entertainer, is now past, though he has left a nasty taste in the mouth of the travelling public.) He is therefore quite capable of distinguishing prickly heat from measles, domestic collywobles from yellow fever. Do not, therefore—I suggest to port authorities—ask of him that most aggravating of all questions for a ship surgeon, "Have you had any cases of illness on board, whether of an infectious nature or not?" What sort of reply is expected to this question? Are details desired of the bo'sun's lumbago, the carpenter's rheumatism, the chief mander's indigestion, the fireman's whitlow, the chief engineer's boil, the stewardess's debility, the third officer's cold in the head, the steward's diarrhoea, the A.B.'s bronchitis, etc.? It is inconceivable that the authorities should have either the time or the patience to peruse such a recital, even if their health declaration form gave sufficient room for its insertion. Personally, I decline to attempt a reply to this question, and simply state—"A few cases of minor illness." Nor can I see what possible bearing such maladies can have on the public health of a port or country.

I trust I shall not be misunderstood. The important point at issue is the early detection of infectious or contagious disease, and on this the interests of port authority and ship surgeon coincide. I am therefore all for the tightening of regulations and examinations, in so far as these serve this end. But I desire to protest strongly against the *futilities* which are everywhere apparent in foreign ports: the deep suspicion with which every case of minor illness is regarded; the answering of questions which suggest that a ship is necessarily a hotbed of filth and corruption; the needless reduplication of health declarations—for example: Why should a ship be obliged to fill up a health declaration form at both ends of the Suez Canal,* whether north- or south-bound? Why should a ship which has made a complete health declaration at Capetown be required to repeat this at all ports on its way round the South African coast, so that at Durban one may be giving particulars of the illness during the outward voyage of some person who has long ago disembarked and reached his home in the interior of the country? Surely, having made a declaration at Cape town, all that should be subsequently required is notification of any further contagious or "prohibited" disease. Why should the same thing occur at British ports, each port authority treating the ship as if she had arrived from say, Hong-Kong, instead of London or Liverpool, no consideration whatever being attached to the fact that she has already been examined and has received "free pratique" at previous ports of call? It is against such *futilities* that I protest, and there are many of them.

* This involves answering eighteen questions at Port Said, thirty-three at Suez, some of them quite ridiculous—for example: "Have you picked up anybody or thing (sic) during the voyage?" If so, where? Give bearings. Imagine a liner stopping to pick up a "thing," and taking bearings on the occasion!

ACCIDENTS IN SEWERS

PRECAUTIONS FOR SAFETY

A report on the precautions necessary for the safety of persons entering sewers and sewage tanks has been issued for official use by the Ministry of Health. It is the joint work of seven representatives of the Home Office and the Ministry, who were appointed a year ago, the chairman being Mr. R. G. Hetherington and the medical members Dr. Thomas Carnwath and Dr. E. L. Middleton. The decision to make the inquiry was reached because of fatal accidents at Upminster and Southend, and because there was no record of an investigation having been made or advice given previously by any Government department. Since then further fatalities have occurred at Northallerton and Coventry. It appeared that while some of the larger authorities issue fairly comprehensive instructions to their employees there is a lack of uniformity in the instructions given, and many local authorities have done little or nothing.

The dangers to be anticipated in sewers and sewage tanks fall naturally under two heads: (1) flooding; (2) gases. In regard to the former, it is agreed generally that bars or chains should be provided at all manholes in sewers, so that they can be fixed across the sewer at the manhole below the point at which any man is working. Gases are grouped into asphyxiating, poisonous, and inflammable. The composition of the air in sewers normally differs little from that of the outside atmosphere, but it may be much modified as a result of stagnation in the sewer due to structural defects, or by the admission of gases or liquids which readily vaporize. Where stagnation occurs the solid matter undergoes fermentation and absorbs oxygen from the air in the sewer. Fermentation or digestion of sewer solids gives rise to very objectionable odours, and if there is little ventilation the evolved gases collect and gradually displace the air, so that the sewer atmosphere becomes irrespirable owing to the reduction of its oxygen content. Of the gases found at times in sewer air due to direct admission, coal gas is the commonest, but acetylene from the decomposition of unspent calcium carbide is occasionally found; both may give rise to explosive mixtures. Of the readily vaporizable liquids that gain access to sewers inflammable wastes from dry cleaning works, etc., are occasionally met with, but petrol is by far the most common, and may cause devastating explosions. Speaking generally, the gases to be feared in sedimentation tanks are those produced in the early stages of the precipitation of sewage solids—namely, CO_2 and H_2S ; whereas the gases to be feared in septic tanks are those evolved in the later stages of fermentation—namely, methane (CH_4) and CO_2 . The danger of asphyxiation by irrespirable gases can only be removed by adequate ventilation of sewers and tanks. In this country the greatest risk encountered is that of poisoning by H_2S . The first and principal remedy is to prevent the accumulation of sewage or sludge by cleaning out tanks and (where necessary) sewers at frequent intervals.

With reasonable care accidents should not occur. The tests and precautions for ensuring safety are relatively simple and ought to be strictly observed. Tests must then be made for H_2S (by exposing lead acetate paper for five minutes), for asphyxiating conditions (by a safety lamp), and for inflammable gases (by a detector lamp). All the men should be well versed in the tests and a life-line should be worn by the first man entering a sewer or tank until safety has been established. So long as any man is in a sewer the three manholes (the one entered and that on either side) should be kept open and two men posted at the entry manhole. Smoking and the use of naked lights are forbidden. Rescue kit should be carried by every travelling sewer gang, and kept apart from the tools and ordinary tackle, the man in charge of the gang being responsible that the kit is at hand and in working order. It should include at least two life-lines and one breathing apparatus.

A summary of the committee's conclusions appears as an appendix to the report and would serve well as a model for leaflets to be issued by local authorities.

England and Wales

London Voluntary Hospitals

The achievement of two records is reported in the statistical review for 1933 of the work and finance of the London voluntary hospitals, which has been issued by King Edward's Hospital Fund.¹ The total maintenance receipts reached the figure of £4,000,000 for the first time; the hospitals with surpluses reached the highest number recorded, while those with deficits were the fewest on record, and the aggregate total of their deficits was the lowest. Most of this increase in total income was due to increased receipts under legacies, but ordinary income also rose by £16,000. There was a small decrease of £18,000 from subscriptions and donations, and another decrease of £24,000 in income from investments, owing to the lower rates of interest prevailing. These two decreases were more than offset by an increase of £58,000 in receipts from services, including the grants of the Hospital Saturday Fund. A factor of growing importance that has contributed to the increase under this head is the contributory scheme of the Hospital Saving Association. Expenditure has been steadily rising, but less rapidly since 1930. Although there was a slight increase in 1933 as compared with 1932 the rise in income was much larger. The number of hospitals showing surpluses in the year under review was ninety-eight, the highest yet recorded, and comparing well with eighty-five in the previous year. Those showing deficits numbered forty-seven, again the lowest figure on record in this respect, and thirteen less than in 1932. The aggregate amount of the surpluses was £303,000, against £201,000 in 1932, while the aggregate amount of the deficits fell to £61,000 from £97,000 in 1932. There was thus an increase of income over expenditure of £138,000, which raised the net aggregate surplus from £104,000 in 1932 to £242,000 in 1933, the largest net surplus for ten years. The general conclusion is drawn that, while the deficits at particular hospitals form a serious problem for those hospitals, they are not typical of the general tendency of hospital finances down to the end of 1933, but are due to more or less exceptional circumstances. The bed complement increased by 190 to 17,340 during the year, making a total increase of 970 since 1929. The total capital expenditure on buildings and equipment rose from £577,000 in 1932 to £582,000, a far lower figure, nevertheless, than those of 1929 to 1931, and indicating one of the effects of the still prevailing financial stringency. Several hospitals have been compelled to defer their appeals for building schemes. Yet it is clear that the work of the voluntary hospitals in London continues to grow both in scale and in quality, as a result of the progress made in curative medicine and surgery, and that in the aggregate the receipts from patients and the general public have kept pace with the increased maintenance expenditure. There has also been issued a summary² of the report of the committee appointed to inquire into out-patient methods at London hospitals as affecting the suitability of patients and the time of waiting. The main recommendations are: that hospitals should be encouraged to develop the consultative side of their out-patient work; that, subject to certain safeguards, non-urgent minor cases should be referred after the first attendance to suitable agencies which provide general practitioner treatment; and that various time-saving methods of procedure or improvements in accommodation should be studied by hospitals with a view to action where appropriate. It seemed to the committee that part of the waiting was unavoidable with large

populations, but that the treatment of an excessive number of minor cases was definitely handicapping the dealing with major cases. It was thought also that improvement was possible as regards the procedure concerning doctor's letters and hospital replies. The question of the fixed time for arrival was commended for more concentrated study. The committee suggested that these recommendations should be so applied as to promote the discovery and adoption of a common policy, while maintaining the individuality and freedom characteristic of the voluntary system. It was added that the King's Fund should consider to what extent it could help in getting the recommendations adopted by making available the detailed information accumulated during the inquiry.

Scotland

Dental Conference in Dundee

The fifty-fourth annual conference of the British Dental Association, held at Dundee from August 7th to 9th, was attended by some 250 delegates, who received a civic welcome from Lord Provost W. H. Buist and a welcome from the University of St. Andrews, conveyed by Professor D'Arcy Thompson. Dr. W. Graham Campbell (Dundee), who was installed as president, said that the Dundee Dental Hospital had been opened in 1914 to make dental services available to the poorer classes of the city, and a few years later a dental school was founded in association with St. Andrews University. This was the only Scottish University up to the present time to provide courses and grant a diploma in dental surgery (D.P.D.), and the speaker, as dean of the school, had received inquiries regarding it from more than eighty dental surgeons holding public appointments in Britain and overseas. It was intimated that the next annual meeting would be held in Plymouth, and Mr. Sydney D. Venning (Plymouth) was elected president for 1935, with Mr. William Guy (Edinburgh) as vice-president. Professor John Anderson of the chair of surgery in University College, Dundee, addressing the conference on the subject of dental practice, said that the dentist had a wider duty to the community than the mere repair of teeth, for he often had the opportunity of detecting at an early stage serious diseases of the mouth or throat. He instanced the case of a young professional football player who, as the result of actinomycosis, had become quite unable to open his mouth. After teeth had been extracted to enable him to be fed, and a course of radium treatment had been administered, complete recovery had taken place and he had been able to continue his professional career as a player of first-class football. The speaker had reviewed 1,250 cases of cancer of the mouth in Dundee, of which 84 per cent. were in men and 16 per cent. in women; among associated factors in causation had been tobacco, chronic infection, rough teeth, and alcoholic excess. It should be recognized by the public that cancer of the tongue was usually preceded by some simple condition, such as dental ulcer, which might be readily cured. Mr. Grantley Smith, municipal dental officer, Bermondsey, contributed a paper on municipal dentistry, in the course of which he said that to make dental benefit a statutory one would go a long way towards solving the problem of adolescent dental treatment. He pointed out that the British Medical Association recognized the necessity for an efficient dental service, but while that Association based medical services upon private practice, dental services were widely different, and the speaker believed that treatment centres would of necessity play a large part in dental services to the industrial public. On the

² King Edward's Hospital Fund for London. (11d. net, post free).

last day of the conference a discussion took place regarding the anaesthetic of choice for dental surgery. Dr. R. R. Macintosh said that the induction of anaesthesia by means of barbiturates had simplified this problem for dentists, but he did not consider that this should tempt the operator to give his own anaesthetic. Mr. I. S. Spain (Norwich) said that in time nitrous oxide with oxygen would probably displace all other dental anaesthetics; for this, however, a skilled anaesthetist was essential. Mr. S. F. St. J. Steadman (London) said that he had found difficulty in persuading patients to avail themselves of a skilled anaesthetist, for the patient commonly had faith in his family doctor as the anaesthetist, and the dentist could not venture to say anything against this. A presentation of his portrait, the work of Mr. Leslie Kinnier (Dundee) was made to Dr. Graham Campbell by past and present students of Dundee Dental Hospital and School, and in making the presentation Mr. William Boyd, president of Dundee Dental Hospital, said that, but for Dr. Graham Campbell and his brother, Dr. Norman Campbell, there might never have been a dental hospital in Dundee, so that it was fitting that this presentation should take place on the twenty-first anniversary of the hospital's foundation.

Ireland

Health Progress in Belfast

Taking as an illustration the almost complete eradication of enteric fever from the county borough of Belfast as the result of careful attention to the water supply, the water-carriage system, and the steady abolition of ash-pits, Dr. C. S. Thomson, medical superintendent officer of health, in his annual report for 1933, surveys the present position generally, and indicates lines on which similar advances might be made in the future in other directions also. The immunization of toddlers against scarlet fever and diphtheria could, he remarks, be organized as an effective safeguard of health if the necessary additional medical assistance could be provided. The housing question is being carefully investigated. There are about 97,600 houses in the city, and in 1933 over 19,500 house-to-house examinations were made as a routine, with 48,000 reinspections, and more than 24,000 for specific purposes. Many houses must be demolished, but this cannot be done until a sufficient number of suitable houses are provided for their inhabitants, to be let at not more than 6s. a week. But bath accommodation could not be supplied at such a figure. Many of the houses so far built are too far from the centre of the city, and their rents are too high. Dr. Thomson enumerates various faulty steps which must be avoided, and expresses the hope that within the next five years it will be possible to make a clean sweep of the various insanitary areas. There are now fourteen weekly infant welfare sessions as compared with six in 1930, and nine municipal ante-natal sessions, three more than in 1932. While continuous supervision is very desirable for women during pregnancy, this cannot be secured satisfactorily by laying stress on the possible difficulties and dangers. What is wanted is the creation of a general feeling that such supervision is a natural and sensible procedure. Such an advance in the education of the public requires the more active co-operation of health associations and societies such as women's institutes and guilds. In this educational effort the most important part should be played by the personal guidance of the medical practitioner, the midwife, and the health visitor, and Dr. Thomson suggests that special attention might well be paid to this subject in the training of the

midwife and in her post-certificate instruction. There has been a gratifying response to the clean milk campaign, and the standard of the samples examined has much improved. Dr. Thomson remarks that the safest kind of milk is not yet available to the public—namely, milk produced under licence from tuberculin-tested herds, and subsequently pasteurized. He adds that, so far as Belfast is concerned, both Grade A (T.T.) and pasteurized milk can be drunk with a fair degree of assurance. A most successful baby week was held in June last year, thirteen years having elapsed since the previous one. The attendance neared a total of 30,000. The total cost was £500, of which £300 was met out of small rent charges made for trade exhibits of a strictly health nature.

Appointment of County Medical Officers of Health

At the last meeting of the Leitrim County Council a letter was read from the Department of Local Government and Public Health with reference to previous correspondence, pointing out that, in pursuance of Section 21 of the Local Government Act, 1925, it was incumbent on the Leitrim County Council to appoint a county medical officer of health. The necessity for the employment of a whole-time sanitarian to reorganize and develop the public health services in the county had become urgent, and was emphasized by the serious outbreaks of infectious disease which had recently occurred in certain districts. Moreover, the need for the organization of a system of school medical inspection in the county was generally recognized. That service was dependent on the appointment of a county medical officer of health. Experience in counties in which that service was in operation had shown that a large proportion of school children were suffering from dental defects, enlarged tonsils or adenoids, defective vision, and certain other physical deformities, the early detection and correction of which would obviate a considerable amount of ill-health in after-life. The provision of school medical service was therefore an insurance against sickness in the later ages, and the cost of that service would be amply repaid by the increased health of the school children and of the community in general, and by a reduced expenditure from the rates on the provision of institutional and other treatment. In this connexion it was explained that the fears expressed by some local authorities that the cost of the county medical officer of health system would be excessive had proved to be unfounded. The experience gained in the eighteen counties in which this service had been operating for some years demonstrated that when the recoupment from the State grants was taken into account the cost of this service to the rates did not on an average exceed one halfpenny in the pound on the valuation of the counties concerned. Having regard to the foregoing circumstances, and in view of the fact that similar officers were now functioning in neighbouring counties, the Minister requested that the county council would forthwith take the necessary steps to appoint a county medical officer of health for the county. The requisite preliminary procedure consisted of: (a) fixing the terms of remuneration for the position, which should not be less than £800 per annum, with vouched travelling expenses; and (b) obtaining from the Board of Health a formal resolution assigning to the county medical officer of health the duties of school medical officer, and allocating a proportion of the above-mentioned total remuneration, say one-half, to the duties of school medical officer, which portion of the remuneration would be eligible for recoupment from the State grant. It was requested that the decision of the council in the matter might be conveyed to the Department by letter immediately after the meeting at which the question was discussed. After a long discussion the matter was adjourned.

Mental Hospitals in the Free State

Dr. D. L. Kelly, inspector of mental hospitals, in the course of his annual report, gives the following information. The number of insane persons under care on December 31st, 1933, in public and private establishments was 20,427. This number does not include insane persons maintained at home by relatives or other guardians, with the exception of such as are under the control of the Chief Justice, or are in unlicensed houses and have been notified to the Department, in pursuance of Section 37 of the Private Lunatic Asylums (Ireland) Act, 1842. Voluntary boarders residing in private mental hospitals are also excluded from the total number. Of the total number under care on the date mentioned 89.3 per cent. were in the district and auxiliary mental hospitals, 4.7 per cent. were in private mental hospitals or in single care, 5.4 per cent. were in Poor Law institutions, and 0.6 per cent. in the State Criminal Lunatic Asylum. The distribution of the sexes was 52.1 per cent. males and 47.9 per cent. females. The changes which took place in 1933 may be summarized as follows: The number in the district and auxiliary mental hospitals increased by 407, the number in Poor Law institutions decreased by 149, the number in private mental hospitals decreased by twelve, the number in single care in unlicensed houses decreased by six; there was no change in the number in the State Criminal Lunatic Asylum. There was an increase of eighty-seven in the number of male and of 153 in the number of female patients under care. Under the Lunacy Acts the Saorstát is divided into eighteen districts. In sixteen districts there is one district mental hospital only. The daily average number resident in 1933 in all these hospitals was 18,164 (9,667 males and 8,497 females). At the end of 1933 the numbers had increased by 1,278 compared with the figures for December 31st, 1932. The number of admissions during the year was 2,703 (125 more than the corresponding number in 1932). In 1933 there was an increase of ninety-two in the number of first admissions, and an increase of thirty-three in the number of readmissions. First admissions were equivalent to 71.9 and readmissions to 18.4 per 100,000 of the estimated population (2,992,000). The total number of patients discharged in 1933 was 1,295. Of these 972 were discharged recovered. The percentage of recoveries on the admissions was 33.2. The numbers relieved or not improved on discharge totalled 323. The total number of deaths was 1,001, which is sixty-nine fewer than that in 1932. Of the total number seventeen (1.7 per cent.) were returned as due to general paralysis of the insane, 200 (20 per cent.) to pulmonary tuberculosis, thirty-six (3.6 per cent.) to epilepsy, and thirty-two (3.2 per cent.) to malignant disease and other tumours, excepting those of the brain. The highest death rate was in Limerick Mental Hospital, where it was 8.3 per cent. of the daily average number resident. The lowest was 4.1 per cent. in Sligo. The general death rate was 5.5 per cent.

The fourth conference of the International Association of Preventive Paediatrics (Medical Section of the Save the Children International Union) will be held at Lyons on Thursday and Friday, September 27th and 28th, 1934. The subjects to be discussed are: (1) the prophylaxis of malaria in children—Professor Cacace (Naples), Professor Gillot and Dr. Sarrouy (Algiers), and Dr. Barclay Barrowman (Batu Blah, Federated Malay States); (2) the prophylaxis of rickets and convulsions—Professor Monrad (Copenhagen), and Professor Rominger (Miel). Those who desire to be present at the conference and to take part in the discussions are requested to communicate with the secretary of the I.A.P.P., 15, Rue Lévrier, Geneva.

CORRESPONDENCE

Is High Blood Pressure a Risk?

SIR,—I am a surgeon. I am tempted to say with Lord Moynihan that I am a physician doomed to the practice of surgery. Recently, being concerned with the maladies of a patient a little over 60 years of age, I thought it right before operating to take the opinion of a physician upon the question of blood pressure. The highly intelligent patient, being interested and incredulous, suggested that we should consult at least two distinguished cardiologists and compare their results. We did so. The physicians chosen for our experiment were men renowned in the profession in this country; for one we may even claim an international repute. The readings given by the two experts, using apparently identical methods and apparatus, within a period of one hour, in an unemotional patient, varied to the extent of 30 mm. in systolic and 18 mm. in diastolic pressures.

Can anyone tell me if blood pressure readings are of any real value; and, if so, of what value? Textbooks are almost silent; experts vary in opinion and advice; and most of us are ignorant, sceptical, or both. I am familiar with documents published by American insurance companies; but I am not aware of any substantial contribution to thought or to literature in this country since Sir Clifford Allbutt's and Dr. Batty Shaw's discussions before the war. Is there any English evidence available to show whether a high blood pressure involves an added risk to life or health; or are we once again the victims of tradition, hearsay, or prejudice?

Every week as I incompetently play my round of golf I watch the highly accomplished performance of two rounds by a friend whose blood pressure has not been known to fall below 285/170 in the last ten years; and one of the most eminent of my professional colleagues frequently repeats to me a statement I first heard him use during the war: "I feel a worm if my systolic pressure falls below 200." Only this week I have performed, without the slightest anxiety, two major abdominal operations upon patients whose blood pressures were over 250/160. Is it possible to provoke an Anglican authority (if there be one) into speech?—I am, etc.,

August 20th.

M.S., F.R.C.S.

Action of Ultra-short Waves on Tumours

SIR,—In a preliminary note communicated to the Zurich International Conference of Radiology Dr. Reiter claimed that

"a limited wave-length with its maximum at 3.4 m. had the effect of destroying tumour cells if applied with a certain dose, a definite number of times, and also at definite intervals. Other wave-lengths under the same conditions did not produce this effect. The destruction of a tumour under these conditions is very often attended by a certain amount of destruction of surrounding tissues."

Crabtree and Cramer (1933) found that it was possible to increase the sensitivity of cancer cells to radium by chemical or physical means. The action of a small radium dose only able to slow down the growth could be converted by the action of these means into a total destruction. Unfortunately, the substances and methods by which these effects were obtained by these authors are such as to make their use in human therapy impossible. As the effect of ultra-short waves can be applied in human therapy, Dr. Reiter has investigated the combined effect of a weak dose of ultra-short waves and a weak dose of γ -radiation on human cells.

In collaboration with Dr. W. Cramer, at the Imperial Cancer Research Fund Laboratory, a mouse tumour was first treated with a weak dose of ultra-short waves; then the animal was killed and the treated tumour removed and cut into thin slices. Half of these were treated *in vitro* with γ -radiation equivalent to 55 mg. radium element for three hours. A normal untreated tumour was also divided into two parts, one treated with the same dose of radium and the other kept as control for testing the normal growth. Small pieces of each of these four groups were then inoculated into eight mice and the growth of the tumour charted. The action of the combined treatment was then investigated independently from effects on the blood circulation. It was found that with a weak dose of ultra-short waves which did not damage other tissues and which did not by itself produce any change in tumour growth, when combined with the radium dose which by itself was ineffective, the two together prevented growth of the tumour.

In a second series of experiments carried out at the St. John Clinic and Institute of Physical Medicine the growth of Jensen rat sarcoma tumour in rats was investigated (1) when treated with a weak dose of ultra-short waves, (2) with this plus a weak dose of radium, and (3) with radium only. Here again some evidence was obtained that a preliminary treatment with ultra-short waves made the tumour susceptible to radium, either agent being ineffective in itself, and the dose of ultra-short waves being too weak to cause serious injury to normal tissues.

In regard to specific action Dr. Reiter, in the Clinic laboratory, has shown that, taking a dose (1) of 3.4 m. ultra-short waves, (2) of 4.5 m. waves, the dose being measured by thermometric means, the former prevents tumour growth while the latter does not. Given a greater dose the 4.5 m. waves may be effective. Waves shorter than 3.4 m. have not so far been tested. The 3.4 m. waves are effective when cooling is carried out so that there is no evidence of rise of temperature of the tumour as a whole to a degree which in itself would be lethal. Further investigation obviously is needed.—I am, etc.,

LEONARD HILL,

Aug. 20th.

General Supervisor of the St. John Clinic.

Thrombosis of the Penis

SIR,—Mr. Clifford Morson's distinction between true priapism and penile thrombosis is most valuable and not generally recognized. He refers, however, to penile thrombosis in leukaemia in a manner which suggests doubt as to its actuality. A good summary of the literature of this condition is given by H. Hirschfeld in Schittenhelm's handbook of diseases of the blood (Berlin, 1925, vol. i, p. 327). There are over thirty papers on the subject in relation to chronic myeloid leukaemia. In the same textbook reference is made to its rare appearance in acute lymphatic leukaemia (p. 391); but it is always open to question whether these are not in fact acute cases of myeloid leukaemia.

I have myself seen one case of penile thrombosis in chronic myeloid leukaemia: it was the first symptom of the disease, and persisted for about fourteen days, reacting eventually to α -radiation of the spleen and penis. The patient was thereafter impotent, and died two years later of leukaemia. Most pathologists who see a large number of cases of myeloid leukaemia have seen it at some time. Venous thrombosis, involving the femoral or saphenous veins, is exceedingly common in this disorder, and the splenic infarcts, which are practically invariable, are of this nature; it is not therefore strange that the corpora cavernosa should thrombose. When complicated by fre-

quency and strangury (as in the case seen by me), owing to passage of urate gravel from the increased purine metabolism, the condition is exceedingly distressing.

By a coincidence there was in the ward at the same time a case of priapism following a war-time bullet wound of the spine. The patient made an application, which was not successful, for an increased pension owing to his disability.—I am, etc.,

Westminster Hospital, S.W.1,
Aug. 16th.

R. J. V. PULVERTAFT.

SIR,—I have read with interest Dr. Parkes Weber's letter (*Journal*, August 18th, p. 329) with reference to my article on thrombosis of the penis (*Journal*, August 11th, p. 249). It is important to know what was the subsequent history of his two cases of "persistent priapism" due to myeloid leukaemia.

It is my experience that when the thrombosis is due to arterial disease impotence follows, though sexual desire is unaffected. Your correspondent sees no reason why these cases should not be classed under "persistent priapism." If he will read my article again he will, I am sure, accept my view that this is a wrong description. Priapism is a condition which simulates the organ when sexually excited. In thrombosis of the corpora cavernosa there is no enlargement of the glans penis, and therefore the condition is not one of priapism.—I am, etc.,

Kingston Gorse, Sussex, Aug. 19th.

CLIFFORD MORSON.

Haemorrhage from Peritonsillar Abscess

SIR,—Professor J. B. Dawson's letter on the above subject (*Journal*, August 11th, p. 284) recalls a similar case which occurred in my practice, and which is, I think, worth recording from the point of view of treatment.

A very large fat man (he weighed 17 st.), aged 38, a victim of nephritis and emphysema, developed a left-sided peritonsillar abscess, which was incised by one of my colleagues. Bleeding recurred at intervals in spite of every effort to control it, and had reached a highly dangerous stage by the time I saw him (October 16th, 1926). The patient was very white, weak, and apprehensive from continuing loss of blood. The pharynx was almost closed by bulging clot, some of which was protruding from the faucial incision, from which came a steady trickle of blood. As a general anaesthetic was out of the question the neck was infiltrated with novocain and the external carotid doubly ligated at the site of election. As in Professor Dawson's case, a mass of swollen lymph glands required removal before the artery could be exposed. The efficacy of this procedure was immediately demonstrated by the fact that my colleague enlarged the faucial wound and cleared out the mass of clot without any sign of recurrence of the bleeding. The patient made a rapid recovery.

As a result of this experience I am in entire agreement with Professor Dawson as to the wisdom of tying the external rather than the common carotid when confronted with dangerous bleeding from a peritonsillar abscess, whether spontaneous in origin or following incision.—I am, etc.,

Dublin, Aug. 15th.

CHARLES MACAULEY.

The Swab in Diphtheria Diagnosis

SIR,—I write lest certain letters you have recently published should be taken seriously as suggesting that swabbing of suspicious throats can be excusably omitted.

In the two districts of which I am medical officer of health we provide laboratory facilities and also pay the doctors a fee of five shillings for every swab they send for examination. We let it be known we want every

sore throat swabbed. After ten years' experience of this the following facts emerge.

1. The incidence of the disease has been halved.
2. The deaths have been halved in one district and none have occurred in the other.
3. Many swabbed throats in which no clinical resemblance to diphtheria was present are found to be diphtheritic, and others which appeared quite characteristic are found to be negative.

The cases discovered unexpectedly to be diphtheria are removed to hospital, and other persons they might have infected are saved—hence the diminished incidence referred to. The apparently certain cases which prove negative are not removed, and so far no diphtheria has followed their remaining at home.

I am quite certain that in many early cases there is no clinical sign by which anyone, however great his experience, can diagnose diphtheria. Disappointment with swabbing will be found in districts where, in the absence of any encouragement to assist the public health authority, the doctors, or some of them, only swab cases they suspect are diphtheria. It is among the cases in which no one—not even Drs. James and Sanctuary—would suspect diphtheria that the ambulatory and therefore dangerous case is found.

As it is certain that any sore throat may be diphtheritic, and therefore every case is a "doubtful case," it is obviously impracticable to have, as suggested, every case examined by an expert, and even if this were possible no expert opinion is of any value in a really early case. It is also impracticable to put every sore throat into hospital or to give every patient suffering from sore throat 20,000 units of antitoxin.

It is not, however, impracticable to swab every case, and I have proved its efficacy.—I am, etc.,

Altrincham, Aug. 20th.

ARTHUR T. BLEASE.

SIR,—In his devotion to scientific orthodoxy Dr. Alistair French (*Journal*, August 18th, p. 332) has quite missed the main point of my original letter, which is that the swab is an unreliable guide, even in cases which are, or ought to be, clinically obvious, and that many lives are lost either because of the faith placed in the swab or because of the delay involved in taking recovery. If Dr. French doubts this, let him ask the superintendent of any large fever hospital.

As to carriers, Dr. French should remember that, for every supposed carrier whom he succeeds in isolating, there are many more at large who are probably doing a useful work in helping to immunize the susceptible population. Further, a report that organisms morphologically resembling Klebs-Loeffler bacilli are present in a culture is not a sure indication that the person concerned is a carrier or disseminator of virulent organisms. In certain circumstances the swab can give invaluable information, but the present policy is often dangerous to the patient and misleading to the practitioner.—I am, etc.,

Isolation Hospital, Romford, Aug. 18th.

E. JAMES.

SIR,—I agree with Dr. French that the throat swab is sometimes the only means of knowing that the patient is a diphtheria carrier and therefore a source of danger to others. There can be few general practitioners of any experience who do not recognize a typical diphtheritic throat when they encounter it.

It is the doubtful case that requires a confirmatory swab. Generally these doubtful cases are not very ill—that is why they are doubtful. Consequently, I think one is justified in taking a swab and awaiting the result. I

recently had four measles cases (two in one house) in which there was a complaint of slight sore throat. All four swabs were positive, and yet there was nothing to be seen on the fauces in any one of them.

Another point brought up recently in another medical publication is the risk in certain cases of administering serum to cases subsequently proved to be non-diphtheritic. Although I personally have had no untoward results beyond a rash, there is no doubt the risk exists. What, then, is the position of the family doctor who, on seeing a "doubtful" case, takes a swab and gives antitoxin at the same time, if his little patient develops gangrene and sloughing at the site of injection, the swab having been returned negative? Would it be looked upon by the child's parents as a justifiable mode of procedure?

Of course, when the throat is obviously diphtheritic with the usual toxæmia (and this is an important point in differentiating the "true" from the "doubtful") the course of procedure is clear.—I am, etc.,

Pitsea, Essex, Aug. 18th.

D. MACLEOD GRAY.

SIR.—This interesting correspondence raises important issues to the general practitioner: (1) When is a "swab" necessary for diagnosis? (2) When is it necessary for other purposes? (3) Should "swabbing" be abandoned? (4) What value is to be attached to the result of a swab? (5) Are "area diphtheria specialists" required?

1. Diphtheria starts at a definite spot and spreads from that spot producing toxic symptoms—a frequent pulse out of all proportion to the temperature. It should present no difficulty in diagnosis from acute follicular tonsillitis, which shows many different spots (pus at the mouths of the follicles) with a higher temperature and a pulse proportionately rapid. Therefore, for a clear clinical case of diphtheria the swab *per se* is not necessary *purely* for diagnosis.

2. It may be necessary (a) for confirmation of the diagnosis both for the practitioner and for the patient or relatives; (b) to give assurance to parents—and in these days, when so much newspaper reference is made to "swabs," many parents will not be satisfied with anything less; (c) for the detection of a "carrier"; (d) in "contacts" to acquire early information about the spread of an infection; (e) for information in the immunization of a patient against diphtheria; (f) for the determination of Vincent's angina; (g) in the exclusion of diphtheroid bacilli in certain inflammations of the fauces; and (h) perhaps in some cases of scarlet fever, which is frequently complicated with diphtheria bacilli.

3. The above summary under (1) and (2) gives a definite negative reply to question (3).

4. A "positive" report of a swab is "positive" existence of the diphtheria bacilli, and is presumptive evidence of the existence of the disease. The "positive" evidence of the existence of the disease diphtheria is the existence of the membrane and its clinical signs and symptoms. The existence of non-virulent diphtheria does not mean the existence of the disease, though it may or may not mean a *potential* carrier. A negative report is no proof of the non-existence of the disease. I have had "negative" reports on cases sent to hospital and "positive" reports from other laboratories. Why some swabs are negative and others from the same case positive I cannot explain. The clinical picture in diphtheria is clear and is the most reliable evidence of the disease.

5. "Diphtheria specialists" are most definitely not required. It would make the situation worse by the practitioner in many cases throwing the responsibility on the specialist. It would make the practitioner, in many cases, less alert in his diagnosis and in shouldering his

responsibility. The creation of this class of inspectors would be another source of interference with general practice. It cannot be justified on the point of mortality, since whooping-cough kills more than measles, and more than scarlet fever and diphtheria combined. The appointment would be on wrong lines, for surely with such a cheap and easy method as immunization against diphtheria existing it is preferable, and advisable, that the public should be educated and induced to have their children protected against the disease, than to have to pay "inspectors" to diagnose a disease and further ridicule the general practitioner to the laity.—I am, etc.,

Ilford, Aug. 18th.

A. G. NEWELL, M.D., D.P.H.

SIR,—The discussion *re* the advisability of "taking a swab" in any suspicious case is surely unnecessary to-day. Every student in my time in the "Glasgow" school was taught the absolute necessity of "having a swab" done immediately, and whilst awaiting bacteriological confirmation to give either antitoxin or horse serum (10 c.cm.). Failure to do so was borne in on us as an heinous crime, so that I feel assured we have all made certain of carrying out this valuable aid to aborting progress of the condition if positive; if negative no harm is done. The additional expense incurred is negligible as compared to the consequences if time be lost.—I am, etc.,

Salford, Aug. 18th.

R. H. ABERCROMBIE, M.B.

SIR,—Writing as a bacteriologist whose work involves the examination of a large number of diphtheria swabs in the course of a year, I find it very depressing to realize that there are still practitioners who, when diphtheria in an acute stage is suspected, make the sometimes fatal mistake of waiting until they have received the result of a bacteriological examination before injecting antitoxin: through the agency of such the laboratory becomes a source of danger in the place of the help which it should be. At the same time I feel that the bacteriologist does not always take advantage of methods available for making an expeditious or even immediate diagnosis, and that therefore some of the delay which may have such disastrous results is often quite unnecessary.

It can be stated with confidence that in the majority of cases of acute diphtheria from which a satisfactory swabbing has been taken the disease can be diagnosed on the examination of the direct smear. But from the perusal of recent literature and from conversation with other bacteriologists I have gathered the impression that, in this country at any rate, examination of the direct smear is not considered worth doing in many laboratories. I am convinced that this position is quite wrong. In this laboratory, during the last twenty-three years, we have examined 272,000 swabs. Of these, 76,000 have been from "acute" throats. In such "acute" swabs as were "satisfactory" (that is to say, when there has been sufficient material to make an examination possible) we have been able to detect the diphtheria bacillus in about 85 per cent. of those from which this organism was subsequently grown on cultivation. These swabs have come, generally by post, from all parts of Kent; if we had been able to take the swabs ourselves and examine them without any delay I am confident that the proportion of successes would have been higher.

The method employed is the hanging-drop modification of Pugh's toluidin-blue stain (*Lancet*, July 6th, 1912). After a little practice with this extremely simple and rapid, though perhaps rather unusual, method, my experience has been that bacteriologists soon feel able to recog-

nize with confidence in the direct smear the somewhat irregular but characteristic appearance which the bacillus shows—an appearance which is often very different from that of the typical organism after growing on a culture medium—and their diagnosis is confirmed by the subsequent cultivation. The only pitfall which must be avoided results from the fact (for which I am unable to give any explanation) that in adults diphtheroid organisms are sometimes seen which closely resemble the diphtheria bacillus as seen in swabs from a child's throat. Consequently, we do not report on direct smears of swabs taken from a patient over the age of 18. For obvious reasons also we do not report on a direct smear which appears "negative."

Surely a method by which such results can be obtained is worth investigation and adoption as a laboratory routine. In many cases the regrettable "waiting for the result of cultivation" would be avoided.—I am, etc.,

CONSTANT PONDER,

Maidstone, Aug. 20th.

Bacteriologist, Kent County Council.

The G.P., the Schoolmaster, and the Specialist

SIR,—A few years ago I wrote to the *Journal* on the decay of courtesy and the increasing lack of the minor graces in the profession. I am a general practitioner and also an M.O. to a school. Among other examples which I cited, I complained that, when at the end of term I wrote to family doctors concerning patients of theirs the majority failed to acknowledge my letters, term after term. Having taken the trouble to obtain their names, and given up an appreciable amount of time to the task, I was annoyed. Surely it ought to be regarded as common courtesy to acknowledge any letter from a colleague!

Further, at the beginning of term often one or two pupils return who have been ill during the holidays and still require some attention, and it is quite common for instructions to be sent to me by a parent or guardian, with a vague history of what has been the matter, and also some unknown medicine, pills, and so on; but no word from the family doctor, from whom the instructions presumably emanated. I have even had, from a parent, instructions as to how I was to give a vaccine. These instructions apparently came originally from a well-known London consultant. That consultant must have known that the patient was returning to school, yet neither he nor the family doctor communicated with me. Needless to say I declined to have anything to do with the unknown vaccine. How pleasant is the contrary, when one receives a short note from the family doctor, enclosing the specialist's remarks for perusal.

This lack of courtesy and efficiency is not universal. There are several doctors with whom one has periodical correspondence during the school life of one or more of their patients, and with whom one's relations are cordial and interesting. Of course the school doctor ought to send any observations to the family doctor, and make it clear that those observations are subject to the opinion of the latter. As for myself, I do not write so many letters at the end of term as I used to do!—I am, etc.,

Maldon, Aug. 14th.

IVAN M. PIRRIE.

SIR,—In those schools which, like Rugby, Wellington, Marlborough, Tonbridge, Lancing, and Christ's Hospital, have an infirmary or sanatorium where all except the most trivial cases are sent the matter is simple. The school medical officer forwards reports to the parents or to the family doctor, as he thinks fit, notifying the house-master as occasion requires, who is thus saved much worrying correspondence.

In those schools where sick boys are nursed in the houses the matter is usually more complicated. The housemaster, who acts *in loco parentis*, obtains information about the patient from the school medical officer, from the house matron or special nurse as the case may be, and possibly also from his wife, who visits the boy during the day. His letter to the parents is thus likely to contain a mixture of medical and nursing information, which often ill describes the actual condition of the boy, in some cases arousing undue anxiety, in other cases failing to allay it.

When the letter has in due course been forwarded to the parents, what is the next procedure? As I know by experience, the parents go to the family doctor to get his sympathy and opinion, showing him the housemaster's letter, which very often may just lack the precise information to enable the doctor to reply satisfactorily to the parents' questions. The family doctor may then suggest that he will get into touch with the school medical officer, which he does by telephone or letter according to the urgency of the case, and with fresh or more technically explained facts at his disposal he approaches the parents once more. Is not this, which is in no sense an exaggeration, a most cumbersome procedure, and one causing needless anxiety to those involved? Furthermore, it is inefficient, since the medical officer's views on their way to the parents or family doctor are liable to get an admixture of misrepresentation.

My suggestion is as follows. All parents would be notified by the school authorities in a circular somewhat as follows:

"During term the school medical officer will report any case which he considers may become serious directly to the family doctor, and keep in touch with him as long as is necessary. The parents will thus get first-hand reliable information in regard to the progress of the illness. In addition to this the housemaster will, as usual, communicate at his discretion in general terms directly with the parents."

There is a further most important point gained by this method, which safeguards the housemaster and the school in those cases which, fortunately but rarely, end fatally or in some way disastrously for the boy. There is no loophole for mistake, as exists in the indirect method of reporting sickness. The school medical officer, supported in his direction of the case by the family doctor, is well able to answer any complaints of negligence, which from time to time are actually made by parents and which at present are borne, quite unjustly, by the housemaster or the school authorities. The school medical officer and the family doctor are, as is well known, safeguarded by their organizations, which deal efficiently with such complaints and so absolve the school from much unnecessary responsibility.—I am, etc.,
Bournemouth, Aug. 20th.

W. SAVILE HENDERSON.

Use of "Oil" Vaccine in Rheumatism

SIR,—We have read with great interest Dr. Warren Crowe's letter in your issue of August 4th (p. 233) on the use of "oil" vaccine in rheumatism. As was pointed out in our original paper (*Journal*, March 10th, 1934, p. 424), we have given very large doses of tuberculin and many other vaccines in combination with an olive oil emulsion without producing any reaction. Dr. Warren Crowe's injections were apparently made with a 3.5 per cent. emulsion, which is the percentage of the dispersed phase in the preparation we used in our original experiments with tetanus and diphtheria toxins. Since that time we have injected various vaccines with an increased percentage of olive oil (5 to 10 per cent.), our reason being that from the point of view of determining the

amount of adsorption the available* surface area of the dispersed phase is the only factor concerned. The preparations we are now using are produced by the Glaxo Laboratories on the special apparatus described by us last year in the *Journal of Physiology* (1933, lxxviii, No. 4, 467). We are given to understand that supplies of such finely dispersed emulsions are available for research workers.

At the present time we have under observation a large number of cases of surgical tuberculosis being treated with a mixed vaccine of tuberculin and oil. In the preparation of this tuberculin tubercle bacilli have been dissolved by a process which will shortly be published, and it is worth recording that *minimum* doses of 1/2 mg. are being given with extremely encouraging results and no untoward reactions. We are getting similar results with other vaccines—for instance, streptococcal, staphylococcal, *B. acnes*, etc.

We should be interested to know the size of the particles in the dispersed phase of the preparations with which Dr. Warren Crowe has been working. In our own experiments results have been unsatisfactory with particles as large as 2 to 2½ μ .—We are, etc.,

St. Mary's Hospital Medical School,
Aug. 14th.

Proposed Medical School for Women

SIR,—A daily paper has recently announced that plans are being considered for starting a medical school for women at the West London Hospital. The time is hardly ripe for any official or detailed account of a scheme which is still in the earliest stages of embryonic life, but as the news has appeared in the lay press I feel that it would be wise to make known to the profession, through your columns, the facts of the case.

It is true that the possibilities are being explored, but at present the proposal has not received the sanction of the Board of the hospital, and no official approach to the university has been made. Developments are not to be expected until after the vacation. As soon as any definite decision is made the details will doubtless be communicated to the profession through the medium of the leading medical journals.—I am, etc.,

Aug. 18th.

MAURICE E. SHAW, M.D., F.R.C.P.,
Vice-Dean of the Post-Graduate College,
West London Hospital.

Origins of Sherlock Holmes

SIR,—In the *Journal* of August 11th (p. 278) it is stated that "when practising . . . at Southsea, Conan Doyle hit on the idea of an amateur detective who should apply the methods of Joseph Bell, etc." With all due modesty, and respect for the writer of this, I think this statement is somewhat fictitious. When a student at Liverpool in the late 'nineties I read a paper on Sherlock Holmes to the Students' Debating Society. The chairman on that occasion was George Hamilton, assistant honorary surgeon to Mitchell Banks, and he took the opportunity thus afforded to tell us of his own acquaintance with Doyle, when both were students at Edinburgh. He told us that at that time Conan Doyle, deeply interested in Poe's detective works, but recognizing that they were "caviare to the general," told Hamilton that he had the idea of writing detective fiction according to the system of Poe, but greatly simplified and brought down to the level of ordinary people. I do not think that this fact has previously been published.

After Poe, what poor stuff Doyle's is! As Blatchford expressed it long ago: "There was enough genius in Poe's little finger to make a score of Conan Doyles."—I am, etc.,

Harston, Cambridge, Aug. 13th.

W. J. YOUNG.

Occupational Therapy

SIR,—Prevention being better than cure, a further consideration here arises. If occupation has proved such excellent treatment for nervous ailments, may we not suppose that the chief cause of the widespread nervousness which afflicts our age, with its characteristic resort to the dope, increase of insanity, suicide, war-fever, etc., is simply—unemployment?

This is very largely true, but it is not the whole truth; for, broadly speaking, there are two kinds of work. One is creative, self-expressive work, and the other is machine-minding. In my opinion the general mental and moral enfeeblement of our time has been brought about, not only by the sheer idleness of many, but by the steady subordination of others to the machine. And, of course, there are vicious circles too; much "employment" means turning out machine-made goods which only the perverted taste of idlers would call for. Mental prophylaxis therefore demands that as many people as possible should at once get back to self-expressive, creative employment.

How is this to be done? Not, I think, by the Government, which has already taken on much more than it can perform. Perhaps the mental welfare councils will be thinking this problem over in the meantime. It would be interesting to know their answer.—I am, etc.,

File, Aug. 13th.

A. J. BROCK.

Breach of Professional Confidence

SIR,—I should be very grateful if you would bring to the notice of your readers the following instance of breach of confidence with regard to medical reports for compensation cases, as I feel that a very big principle is involved.

I had several times examined a man, from the surgical point of view, for an insurance company, and a colleague examined him from the medical side, both of us reporting fully and frankly to the insurance company concerned. When I was recently asked to examine the man I found, to my surprise, that he had in his pocket copies of my own and my colleague's reports, and also of the report of a surgeon who had examined the man for his own solicitor. He was thoroughly disgruntled about various remarks made by myself and my colleague, and had evidently brooded over these reports until he was obviously in a condition of neurasthenia and yet extremely resentful that it should have been suggested that there was any connexion between the payment of compensation and his disability.

Possession of the report of the surgeon who examined him for his own solicitor had had a particularly bad effect on him, and the moderate physical disability from which he suffers was enlarged to cover his whole mental horizon. I took the matter up with the insurance company for whom I was reporting on his condition, and they informed me that they had exchanged medical reports with the man's solicitor and that the solicitor had without their consent or approval handed them over to the man on his insisting on seeing them. The insurance company wrote to the solicitor protesting at this breach of confidence, and apparently he admitted his error and expressed regret.

I feel, however, that this is a glaring instance of breach of professional confidence, and that the medical profession

generally should be warned to insist that these reports are confidential, and under no circumstances, without the consent of the examining doctor or surgeon, should they be shown to the person examined.—I am, etc.,

August 16th.

CONSULTING SURGEON.

The Treatment of Lupus Vulgaris

SIR,—At the conclusion of a discussion on the treatment of lupus vulgaris at the Annual Meeting, reported in the *Journal* of August 18th (p. 322), Dr. Lomholt disposed of the question of the use of tuberculin in this disease by remarking that it "had been tried extensively at the Finsen Institute, but it had been abandoned." In the *British Journal of Dermatology and Syphilis* (May, 1934), Dr. Robert Aitken of Edinburgh, writing on the treatment of lupus vulgaris, concludes his article with the statement, "Tuberculin as a remedy has undeservedly fallen into disrepute," and in the February issue of the same journal there is a record of cases of lupus treated with tuberculin with considerable success. The worst of these cases, W. W., is still under treatment, and shows no sign of breaking down during the nine months that have elapsed since, notwithstanding the extensive area involved. Other patients have been similarly treated and are showing improvement.

It is wrong and unscientific to condemn tuberculin without an adequate trial. The endeavour should be made to learn how to use it. Knowledge of tuberculin in its widely different actions in different individuals is in its infancy. My object in writing this letter is to draw the attention, not only of dermatologists, but of all interested in the treatment of tuberculosis to the value of the clinical work now in progress in London and elsewhere in establishing the truth about the value of tuberculin.—I am, etc.,

H. S. BURNELL-JONES, D.P.H. OXON.

Hayes, Kent, Aug. 20th.

Infra-red Rays in Treatment of the Septic Hand

SIR,—Those engaged in the practice of physical medicine who read the discussion on "The Septic Hand," which took place at the Annual Meeting of the Association (*Journal*, August 4th, p. 220), must indeed be surprised that not one of the participants seemed to be aware of the benefits to be derived from the application of infra-red irradiation to any septic focus.

It has been proved by clinical observation that in the treatment of boils, carbuncles, and septic processes generally this should be the treatment of choice. If it is instituted early, and not adopted as a last resource, such conditions rapidly clear up. Local treatment should be combined with focal ultra-violet irradiation, and also general ultra-violet irradiation in order to increase the bactericidal power of the blood and the general resisting powers. If treated early enough septic processes may be aborted and saved from the surgeon's knife. If incision is deemed necessary the evacuation of pus is expedited by means of infra-red irradiation, which acts as a super-fomentation in such cases. In addition, pain is markedly relieved from the very commencement of treatment by the sedative action of the rays on nerve endings, and by the increased blood supply produced.

I have fully described the method in my book *Therapeutic Uses of Infra-red Rays* (second edition). Surely it is time that a method which has been in vogue on the Continent and in America for many years should be given an extended trial in this country.—I am, etc.,

London, W.1, Aug. 8th.

W. ANNANDALE TROUP, M.D.

Obituary

GEORGES DREYER, C.B.E., M.D., F.R.S.

Professor of Pathology, University of Oxford

Professor Georges Dreyer, whose death occurred on August 17th at the age of 61, was Danish by birth, the son of Captain G. H. N. Dreyer of the Danish Royal Navy. He was born in Shanghai and educated in Denmark, taking the degree of M.D. in the University of Copenhagen. His scientific education was unusually wide, and it was supplemented by post-graduate studies and research in Germany and France. In 1900 he married Margrete Jørgensen of Sølstedgaard, Laaland, who survives him. There are no children.

In Denmark Dreyer was greatly influenced by Salomonsen, whom he regarded as a great teacher, and was deeply interested in the work of Arrhenius and Madsen on the application of chemical and mathematical principles to

immunology. His own early researches on the biological action of light, accurate measurements of blood volume, methods of estimation and dosage of toxins, and the improvement of the Widal test by the use of standardized sterile suspensions all bear the mark of pioneer work in the introduction of accurate quantitative methods in biology, which was one of his main aims and achievements. Largely on the strength of his brilliant researches Dreyer was appointed professor of

pathology in the University of Oxford in 1907 at the unusually early age of 34, and he was forthwith elected a Fellow of Lincoln College, where the loss of a loved and highly valued colleague will be most deeply felt. His great energy and driving force soon enabled him rapidly to raise the Oxford School of Pathology to a high level of reputation both for teaching and for research.

At the outbreak of war in 1914 Dreyer was appointed a member of the Pathological Advisory Committee to the Army Medical Service, where he took the initiative in pressing for "triple" inoculation in place of inoculation against typhoid only. At the same time he saw his opportunity both of serving the country and of popularizing his improved method for the Widal reaction by arranging with the new Medical Research Council for a service laboratory at Oxford to supply sterile standardized suspensions to the Army and Navy for the diagnosis of the enteric fevers. Under his general supervision this "standards" laboratory has continually enlarged its scope, and now serves an empire-wide public of bacteriologists with high-grade standardized materials for the diagnosis of numerous infections. In 1915 Dreyer was commissioned by the R.A.M.C. and sent to Wimereux to organize the laboratory diagnosis of enteric fever and dysentery, which he carried out with outstanding ability and success. While in France he turned his attention also to the physiopathology of high flying, and invented a most ingenious self-regulating apparatus for the automatic supply of oxygen to airmen. In 1919 he was decorated for his war services with the C.B.E. In 1921 he was elected a Fellow of the Royal Society, being already a Fellow of the Royal Danish Academy of Letters and Science and an Officier de l'Instruction Publique in France.

Having always been dissatisfied with the facilities for pathological research and teaching in Oxford, Dreyer was

delighted, in 1927, to seize the opportunity offered by Sir William Dunn's trustees to build a laboratory worthy of his chosen science and of the University which he so greatly loved. Meanwhile he gave much valuable time to service on the Hebdomadal Council and the University Chest, and was also for a period a member of the Medical Research Council.

During the main part of his life of intense and varied research Dreyer's two main motives were accuracy of technique and the establishment of a series of biological constants in human and animal physiology to act as a basis for the assessment of normality and hence for the detection of pathological states. His well-known work on the relation of vital capacity to body measurements is an instance of research on these lines. "*Das technische ist alles*" was one of his favourite quotations. A great technician himself, with a passion for truth and a contempt for bad experiments, he inspired his colleagues and assistants with the same feelings. He was a very competent linguist, being almost equally at home in Danish, English, German, and French. Moreover, his knowledge of mathematics, physics, and chemistry were greatly in advance of the standard achieved by most other pathologists of his time. But an even more impressive characteristic in his earlier days was a tremendous potential, an irresistible force which overran all opposition or inertia. There were, perhaps, some who for a time felt a trifle aggrieved by what seemed too great an intolerance of conflicting motives or opinions, but with the arrival of full maturity Dreyer's natural affectionateness and generosity soon healed the slight abrasions of earlier controversies.

His contributions to physiopathology and bacteriology have been numerous and important, and have covered a singularly wide range of subjects. Medical science is greatly impoverished by his loss. At all times he was entirely lovable to his intimates, among whom his most junior colleagues and many pupils may be numbered—for Dreyer had no trace of the professional mind, and was himself perennially young at heart. His home was open to all, and his hospitality was remarkable. He was no ascetic, but loved to share with his friends his unusually good table and the excellent wines of which he was an expert judge. Scattered in all quarters of the globe, as here in Oxford and England, are men and women who have drawn their inspiration from the power of Dreyer's passion for truth, and whose hearts have been warmed by his gift of deep and comfortable friendship.

DR. GEORGE A. MOORHEAD

By the death of Dr. George A. Moorhead of Tullamore, Offaly, the medical profession in Southern Ireland has lost one of its oldest, best known, and popular figures. Dr. Moorhead enjoyed a very extensive practice in the midland counties, and his services as a consultant were largely availed of. He was an old and valued member of both the British and the Irish Medical Associations, and by his standard of professional conduct set an excellent example to the junior members of the profession. Educated at Dublin, he became a member of the Royal College of Physicians in 1881, a Fellow of the Royal College of Surgeons in 1893, and took his D.P.H. in 1907. Among the public appointments he held were: medical officer of the Tullamore dispensary district, and surgeon to the district hospital. Early in the campaign against tuberculosis he contributed an important publication under the title of "*Tuberculosis, Retrospective and Anticipatory*," to the *Irish Medical Association Journal*. Although a very busy practitioner, Dr. Moorhead took a keen interest in horse breeding, and kept the best strains of the thoroughbred in his stud at Tullamore.

BERTRAM JAMES COLLINGWOOD, O.B.E., M.D.

Professor of Physiology in the University of London

Professor Bertram James Collingwood, who died on August 5th, 1934, from coronary thrombosis, after a short illness, was born in Sunderland on December 18th, 1871. He was the son of the Rev. C. G. S. Collingwood, rector of Southwark, Sunderland.

Collingwood entered Caius College, Cambridge, in 1895, and joined St. Mary's Hospital Medical School as a student in 1898, qualifying in 1901 and taking his M.D. in 1905. After qualifying he joined the R.A.M.C. as a civil surgeon and served in the Boer War. At the conclusion of the campaign he returned to England and worked with the late Professor A. D. Waller at the University of London Physiology Research Laboratory, which existed at that time at the Imperial Institute; here he was of great assistance to Professor Waller in his valuable researches on chloroform and other general anaesthetics. During this

period a number of important original papers were published by himself, and also jointly with Professor Waller and others. His work in connexion with respiration and inhalation anaesthetics (chiefly chloroform) was of outstanding importance, and served to place the action of chloroform vapour in anaesthesia on a sound scientific basis. Incidentally it added greatly to the safety in the use of chloroform as a general anaesthetic, and clearly indicated the dangers to be avoided by anaesthetists. It was the

work of Collingwood and Waller which first demonstrated that fatalities during chloroform anaesthesia were generally due to the inhalation of a too high percentage of chloroform vapour in the air inhaled. They showed that when the proportion did not exceed 2 per cent. safety was ensured. An apparatus whereby the percentage of chloroform in inhaled air could be regulated was invented by them for actual use in anaesthesia, and this was employed in the operation theatres at St. Mary's Hospital for some years. Collingwood published several papers which emphasized the toxic action of chloroform, and no doubt his work contributed to the development of the view now held in this country that chloroform is an anaesthetic not devoid of danger. He showed that it should be used sparingly when long anaesthesia was required, ether being used wholly or partly in its place when possible. In 1910 Collingwood published, conjointly with W. H. Willcox, a paper entitled "The Therapeutic Use of Alcohol Vapour mixed with Oxygen" (*British Medical Journal*, 1910, ii, 1408), and this mixture came into general use as a valuable stimulant in cases of cardiac failure in desperate illness. He also published several papers on the action of calcium in connexion with blood coagulation, and, in conjunction with Dr. M. T. MacMahon, papers relating to blood coagulation and the action of anti-coagulants, and on the influence of thrombin and anti-thrombin (*Journal of Physiology*, vols. xlv and xlvii). His researches were of great scientific value, and have played an important part in the development of modern therapeutics.

From 1904 to 1909 Collingwood held the post of demonstrator in physiology at St. Mary's Hospital Medical School. In 1909 he was appointed professor in the chair of physiology at University College, Dublin, and he quickly established a reputation as a brilliant lecturer and

teacher. In 1915, after the first gas attack in the Great War, he gave his services to the Research Department on Measures for Protection against Poisonous Gases at the R.A.M.C. laboratories, Millbank. In 1916 he was appointed chemical adviser to the Irish Command, and was given a commission in the R.A.M.C., being promoted to the rank of major in 1917. For his services in the war he was awarded the O.B.E. in 1919. In 1920 he was appointed professor of physiology at St. Mary's Hospital Medical School, University of London, and held this post until his death.

Collingwood was a most devoted alumnus of St. Mary's Hospital Medical School, and never spared himself in giving of his best to his Alma Mater. It is to be feared that this devotion often led to the overtaxing of his strength by doing more than his share of the teaching of physiology, in order that the finances of the school might be helped during difficult times. He was a brilliant lecturer and a fine teacher of the experimental side of physiology. He was most popular with his students, who always felt that in any difficulty he could be approached with the confident prospect of kindly help and encouragement. He possessed great originality of mind, and an attractive personality. He was much loved by his colleagues, students, and all with whom he came in contact in his professional life. St. Mary's Hospital Medical School and the University of London have sustained a great loss by his death.

Collingwood was a nephew of Lewis Carroll, and he devoted great energy towards the establishment at St. Mary's Hospital of a Memorial Children's Ward in memory of his uncle, undertaking a lecture tour in America in 1932 for this purpose. He was instrumental in establishing the Waller Memorial Laboratory in Physiology at St. Mary's Hospital Medical School to commemorate the work of his former teacher and colleague. In 1917 he married Grace Jane Wilkinson, daughter of the late Dr. Wilkinson and sister of Sir Russell Wilkinson. He leaves a widow and three children (a daughter and two sons) to mourn his loss.

W. H. W.

FRANK NYULASY, M.D., B.S.Melb.

Late Honorary Surgeon, The Women's Hospital, Melbourne

The death of Dr. Frank Nyulasy of Melbourne last May deprived Australian medicine of a most distinguished pathological research worker, who had devoted much of his professional life to the problems relating to obstetrics and gynaecology.

Born in Ballarat sixty-eight years ago, he received his medical education in Melbourne, where he graduated M.B., B.S. He then became house-surgeon at the Melbourne Hospital, where he worked under the late Sir Thomas Fitzgerald, from whom he acquired a great ability in the field of surgical diagnosis. His bent then turned more definitely to pathology in connexion with gynaecology, and he wrote a thesis on polypoid endometritis, which was accepted for the degree of M.D., and was subsequently published in the *Journal of Obstetrics and Gynaecology of the British Empire*. A paper read by him at the Medical Congress in Adelaide, on "A Rare Form of Pelvic Tumour," led to his being invited to become a regular contributor to the official journal of the Hungarian National Medical Association. The problems of puerperal infection attracted his closest attention, and the work of Colebrook and his colleagues at Queen Charlotte's Hospital interested him deeply. Not long before his death he supplied a summary of their investigations to the *Medical Journal of Australia*. Possessed of a fine critical ability, and the power of lucid expression, he was a discriminating commentator of the value of new discoveries. In 1905

he was appointed surgeon and agent to the Royal Navy in Melbourne. He was required to attend sailors discharged from British warships, and to perform, in addition, various administrative duties. In 1922 he came to London, read a paper entitled "Puerperal Fever" before the Royal Society of Medicine, and was elected a Fellow.

Of his other activities it may be mentioned that he was keenly interested in research work, and bequeathed a legacy of £1,000 to Melbourne University in memory of his brother, the late Arthur Nyulasy, who was the first to describe correctly the cardinal ligaments of the uterus. For three years he was president of the Royal Victorian Institute for the Blind, and one of the original members of the Big Brother Movement in Australia. An outstanding hobby of his was literature, Shakespeare and Tennyson providing him frequently with topics for lectures, broadcasts, and papers.

DR. GEORGE S. STANSFIELD, O.B.E.

We regret to record the death on August 18th, at his house at Heswall, of Dr. George Sutcliffe Stansfield, who was a well-known figure in Birkenhead for over half a century. Receiving his medical education at Manchester, Dr. Stansfield took the L.R.C.P.Ed. and L.M. in 1873, and the M.R.C.S.Eng. in the same year. In 1874 he began his practice in Birkenhead, retiring in 1921. He became medical officer and medical superintendent to the old Birkenhead Board of Guardians at Tranmere about 1895, and twenty years later, in submitting his resignation, offered on patriotic grounds to continue his services. The Board availed itself of this opportunity, and he remained medical superintendent to the Tranmere Infirmary until 1921. During the war his work increased considerably, and towards its close there were no fewer than 600 beds at Tranmere at the disposal of the War Office. At his retirement the gratitude of the Board of Guardians was shown in its presentation to Dr. Stansfield of his portrait and in its laying to his credit all the improvements which had taken place in the infirmary during his tenure of office. For his work in this connexion he received the honour of O.B.E.

Among his other appointments were that of consulting surgeon to the Birkenhead Borough Hospital and medical officer to the Albert Industrial School. He was one of the oldest members of the B.M.A., having belonged to it for fifty-seven years; he held the position of chairman of the Birkenhead Division in 1924-5. Dr. Stansfield was a pioneer in gastro-intestinal surgery, and it is a moot point whether he was the first or the second to perform in this country the operation of gastro-enterostomy. An interesting personality, with many interests outside his professional work, he was widely known, greatly respected, and much loved. His death will be a considerable loss in the Birkenhead and Liverpool district.

COLONEL C. R. TYRRELL

We have to announce the death at Folkestone, on August 12th, of Colonel C. R. Tyrrell, C.B., C.B.E., A.M.S. (ret.). Born in 1859 Colonel Tyrrell completed his medical education at the Middlesex Hospital, taking the M.R.C.S.Eng., and L.S.A. in 1881. He entered the Army in 1882. Early in his career "Chas.," as he was affectionately known, displayed a character noticeable for soundness of judgement, fearlessness in decision, and a keen sense of duty. These attributes, combined with a genial manner and camaraderie, endeared him to all.

The years 1884-9 found him in India, and after a short spell at home he saw active service on the North-West Frontier with the Utman Khel column and the Buner field force; he was mentioned in dispatches,

obtaining the medal with clasp. In the interval between these expeditions he was specially selected for appointment to the staff of the R.A.M.C. depot at Aldershot. There his soldierly qualities and professional ability found full play, to the great advantage of officers and men who passed through his hands. His knowledge of the handling of men and his teaching experience caused him to be selected as one of the medical staff of the Royal Military Tournament. In 1912, at his own request, Tyrrell was placed on the Reserve of Officers, only to be recalled two years later to the War Office. It was during his service in London that the War Office found full scope for his exceptional qualifications. He joined the Ministry of National Service, worked with unflinching zeal, and carried through to a successful issue a task worthy of his ripe experience and personality.

Tyrrell loved his Corps, and was ever proud of its achievements and distinction, and the great part contributed by the whole medical profession towards the successful issue of the war. He was jealous of its dignity and honour, and its nobility as a corps—as a profession militarized for the specific purpose of relieving suffering humanity. That he and Waggett were partly responsible for the ultimate decision that the R.A.M.C. should have a fitting memorial to those who lost their lives in the war in Westminster Abbey was an abiding satisfaction to him in his declining years. For this enterprise his comrades will always be grateful.

On August 5th, in a London nursing home, the death took place of Dr. THOMAS HUNTER MASSEY, O.B.E., M.C., at the early age of 50. Dr. Massey had but recently retired from the Colonial Medical Service after twenty-four years' service, the majority of which was spent in Kenya. He was of a quiet, retiring disposition, and had a sincere, direct simplicity of character, which endeared him to all who knew him. Always sympathetic and ready to help those in misfortune or trouble, he will be a sad loss to his many friends and comrades in the Colonial Service and outside it. Dr. Massey qualified L.R.C.P.I. and L.M., L.R.C.S.I. and L.M. in 1906, and was appointed medical officer, St. Vincent, West Indies, in 1909. In January, 1913, he was transferred to Kenya Colony, where he remained until last year, retiring as a senior medical officer, to which rank he had been promoted in 1923. During the war Dr. Massey served as medical officer to the King's African Rifles and saw considerable service in the East African campaign, being awarded the Military Cross. On his retirement from the Colonial Service he was made an Officer of the British Empire. Since his retirement from Kenya Dr. Massey had been working at Netley Hospital, and, while on duty there, was taken ill with mastoid trouble. Meningitis supervened, and, despite operative measures, he succumbed.

Dr. JOHN DESMOND GIMLETTE, who died at Cheam on April 24th, was the son of the late Fleet Surgeon, Hart Gimlette, M.D., and was educated at Epsom College and St. Thomas's Hospital. After taking the M.R.C.S. and L.R.C.P. in 1890 he joined the medical service of the Federated Malay States, being residency surgeon of Pahang 1897-1900, and of Kelantan 1909-21. On the outbreak of war he volunteered for military service, and in 1915 received a commission in the R.A.M.C. With the rank of major he was officer commanding troops in H.M. hospital ship *Essequibo*, and later joined the German East African Expeditionary Force as protozoologist. On demobilization Dr. Gimlette returned to his post in Kelantan, but unfortunately, while operating on a coolie, contracted a severe septic infection, from which, after a long illness, with the loss of a leg, he eventually recovered. This ended his life-work in Malaya, where his transparently sincere and sympathetic personality had secured for him the confidence and affection of all, from the Sultan to the humblest peasant, to whom alike he was always ready to

devote his skill. In gratitude His Highness the Sultan presented him with the Kelantan State Medal as a token of his good will and affection. The confidence which he had won, combined with Gimlette's great knowledge of the language and never-failing industry, enabled him to gain a deep insight into the characteristics and customs of the country and its people. In his book *Malay Poisons and Charm Cures*, of which three editions have been issued, Gimlette described, with a fascinating wealth of detail, medicine as practised by the "medicine man" of Malay, and dealt with the various animal and vegetable poisons, some of which, hitherto unknown, have definite therapeutic properties. He was also the author of many contributions to tropical and Malayan medicine. During his last years, with a devoted wife and two young daughters, he was engaged, in collaboration with other workers, in compiling *The Malayan Medical Dictionary*. This, although unfinished at his death, is happily to be completed by one of his co-workers—Mr. H. L. Thompson. By his many friends Gimlette will ever be remembered for his steadfast loyalty and affectionate comradeship.

Universities and Colleges

UNIVERSITY OF LONDON

Professor G. Grey Turner, M.S., F.R.C.S., has been appointed to the University Chair of Surgery at the British Post-Graduate Medical School.

Dr. Amy M. Fleming has been appointed to the University Chair of Obstetrics and Gynaecology (London (Royal Free Hospital) School of Medicine for Women) as from October 1st.

The Services

Surgeon Rear-Admiral G. L. Buckeridge joined the Admiralty on August 15th as Deputy Medical Director-General, in succession to Surgeon Captain C. V. Griffiths, who goes to Haslar Hospital for a course in surgery.

DEATHS IN THE SERVICES

Colonel Theophilus Percy Jones, C.B., C.M.G., late R.A.M.C., died at Cheltenham on July 26th, aged 68. He was born at Ardrea, County Tyrone, on January 6th, 1866, the son of the late Rev. T. J. Jones of Drumard, County Leitrim, and of Tullaniskin Rectory, County Tyrone, and was educated at Dublin University, where he graduated M.B., Ch.B. in 1890. Entering the R.A.M.C. as surgeon lieutenant on July 27th, 1892, he became lieutenant-colonel in the long war promotion list of March 1st, 1915, colonel on January 26th, 1917, and retired in 1921. He served in the Tirah campaign on the North-West Frontier of India in 1897-8 (medal with two clasps), and in the South African War of 1899-1902, when he served in operations in the Transvaal, in the Orange River Colony, and in Cape Colony, including the actions of Johannesburg, Pretoria, and Diamond Hill, Wittebergen, and Ladybrand (Queen's medal with four clasps, and King's medal with two clasps). In the war of 1914-18 he served as an administrative medical officer, as A.D.M.S. in the Mediterranean Expeditionary Force and in France, and as D.D.M.S. in France, and, after the armistice, as D.D.M.S. of the Army of the Rhine; was mentioned in dispatches in the *London Gazette* of July 13th, 1916, December 24th, 1918, and December 30th, 1918, and received the C.M.G. for service in the Dardanelles, and C.B. for the campaign in the Sinai Peninsula. In 1896 he married Ella, daughter of the late Major Watts, Bengal Horse Artillery, and had two sons.

Lieut.-Colonel Duncan Edward Curme, R.A.M.C. (ret.), died at Parkstone, Dorset, on July 30th, aged 63. He was born on January 9th, 1871, and was educated at Cambridge, where he graduated B.A. in 1892, and at King's College, London, and took the M.R.C.S., L.R.C.P. Lond. in 1898. Entering the R.A.M.C. as lieutenant on January 21st, 1899, he was promoted to lieutenant-colonel in the long war promotion list of March 1st, 1915, and retired on March 1st, 1919. He served in the South African War in 1899-1902, when he took part in operations in Natal, the Transvaal, the Orange Free State, and Cape Colony, including the action of Tugela Heights and the relief of Ladysmith, and received the Queen's medal with four clasps and the King's medal with two clasps.

Medical News

St. Thomas's Hospital Old Students' Dinner will be held at the Dorchester Hotel, Park Lane, W.1, on Friday, September 28th, at 7.45 p.m., with Dr. William Longworth Wainwright in the chair.

The annual dinner of past and present students of St. Mary's Hospital Medical School will be held in the library of the new medical school on Saturday, September 29th, at 7 for 7.30 p.m. The honorary secretary is Dr. A. Hope Gosse.

A post-graduate course, open to all medical practitioners without fee, will be held at St. Mary's Hospital Medical School, on Friday, Saturday, and Sunday, September 28th, 29th, and 30th.

The next lecture-demonstration arranged by the Fellowship of Medicine (1, Wimpole Street, W.) will be given by Dr. Clark-Kennedy, at 11, Chandos Street, W., on August 28th, at 2.30 p.m.; the subject will be loss of voice. The following lecture will be on September 4th, on pleural pain. There will be an afternoon course in infants' diseases at the Infants Hospital, Vincent Square, from September 3rd to 14th, which will include demonstrations, lectures, and work in the out-patient department. There will be a course in chest diseases for M.R.C.P. candidates at the Brompton Hospital, from September 10th to October 5th, the instruction consisting of clinical and x-ray demonstrations of cases and pathological demonstrations. A "refresher" course in medicine, surgery, and the specialties will be given at the Westminster Hospital, from September 17th to 29th. Other forthcoming courses include: diseases of the chest, at the Brompton Hospital, September 24th to 29th; proctology, at the Gordon Hospital, September 24th to 29th; demonstration of urological cases, at the National Temperance Hospital, on Saturday, September 8th, at 3 p.m.

The sixth Italian Congress of Anatomy will be held in Rome next October, under the presidency of Professor R. Versari. Further information can be obtained from the secretary, Professor V. Virno, Viale Regina Margherita 289, Rome.

In response to an invitation from the Royal Society the International Union of Pure and Applied Physics will meet in London during the first week of October. The meeting will take the form of a joint conference of the International Union and of the Physical Society, held under the presidencies of Professor Millikan and Lord Rayleigh.

Inspector Gabriel Sacquépée, formerly professor of hygiene at the Val de Grâce Military Hospital and inspector of the services of military hygiene and epidemiology, has been elected a member of the Académie de Médecine in the Section of Hygiene.

Dr. Gaston Ramon, member of the Académie de Médecine and assistant director of the Institut Pasteur, has been nominated a member of the Superior Council of Public Health of France, in succession to the late Professor Calmette.

Professor Dr. B. Spiethoff of Leipzig has succeeded Obermedizinalrat Professor Dr. J. H. Rille as editor of the *Dermatologische Wochenschrift*.

A bust of Georges Clemenceau has recently been unveiled by Dr. Dartigues, president of the Latin Medical Union at Goulet, in Vendée, the last home of the former French Prime Minister.

The University of Groningen has awarded the Guyot prize for the best work in otology during the last five years to Professor F. R. Nager, director of the oto-rhino-laryngological clinic at Zurich, and Professor Max Meyer of Würzburg.

At a recent reception in Berlin Professor Rolfo, director of the Cancer Institute of Buenos Aires, was awarded the Red Cross medal of the first class, which is at present the highest German distinction.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to The EDITOR, British Medical Journal, B.M.A. House, Tavistock Square, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111 (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are:

EDITOR OF THE BRITISH MEDICAL JOURNAL, Athology Westcent, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), Articulate Westcent, London.

MEDICAL SECRETARY, Medisecra Westcent, London.

The address of the Irish Office of the British Medical Association is 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62550 Dublin), and of the Scottish Office, 7, Drumshough Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh).

QUERIES AND ANSWERS

Removal of Tattoo Marks

Dr. GEORGE STEANE (Erdington) writes: Is it possible to remove or obliterate tattoo marks?

Spontaneous Rupture of Extensor Tendons

Dr. GEORGE STEANE (Erdington) writes: Are there any cases on record of spontaneous rupture of the extensor tendons of the wrist and fingers?

Removal of Urine Stains from Clothing

"M.B." (Bath) is anxious to have the name of a chemical preparation which will remove urine stains from clothing, for use in a patient who suffers from incontinence. He would be glad if any reader could assist him.

Local Anaesthetic for Nasal Work

Colonel G. F. ROWCROFT (Coonor, S. India) writes: With all the innumerable anaesthetics now being introduced, has nothing yet been discovered that will take the place of cocaine as a local anaesthetic for the mucous membrane of the nose by surface application, not injection? One occasionally comes across a patient who has a violent idiosyncrasy to cocaine, and nothing as an alternative appears to be available except a general anaesthetic, or some form of injection, often both undesirable, as, for example, such a simple procedure as passing a Eustachian catheter. One that would give analgesia sufficiently prolonged for a submucous resection would be ideal. Any enlightenment on this point will be thankfully received.

Head and Foot Presentation

Dr. ALASTAIR C. THOMSON (Kirtion-in-Lindsey, Lincs) writes: On July 27th I was called by a district nurse to a woman in labour. She was a multipara, and had been losing liquor amnii for four days. The confinement had not been expected until mid-September. On pelvic examination I found a head presenting with, to one side of it, ten "digits," the whole being tightly wedged in the cervical canal. Under deep anaesthesia I was able to push back the head, when I found the "digits" to be toes in a very oedematous state. I performed a combined internal and external version, and delivered a 5½-lb. male child (in the breech manner). Artificial respiration was required for a little time, but the child did very well later, and continues to thrive. The mother made an uninterrupted recovery. The child's legs at birth were easily put into the position of genu recurvatum—obviously due to its position *in utero*—but these now look almost normal. My textbook of obstetrics does not make any reference to this "feet and head" presentation, and I am wondering if any of your readers can tell me if this is a particularly unusual occurrence.

LETTERS, NOTES, ETC.

Holidays for Factory Girls

We have received the following letter signed on behalf of the Factory Girls' Holiday Fund by the Countess of Sandwich, Mrs. Louisa Creighton, the Very Rev. Dr. Hertz, Lady Margaret Loch, Sir Thomas Barlow, and Miss Lilian Braithwaite:

May we appeal to your kind readers for help for the Factory Girls' Country Holiday Fund, which is in urgent need of financial assistance. It may be questioned whether any of us ever outgrow a certain quickening of the pulse at the word "holiday"; it is a fact that the idea yearly increases its hold on our sense of what is due to us. Doctors recommend a holiday, kind friends urge it as a panacea for all the evil effects of overwork and fatigue; it is part of the routine of all our lives—but not, alas! of the lives that probably need it most. The girl who works all day in factory or shop, the woman who looks after her home and also cleans offices in the late evening and very early morning, have little money to pay for what to us is a necessity, but to them an unattainable luxury. When what they earn is wanted for family, rent, food, and clothing, in these days of unemployed men and boys, how can one individual, herself often the breadwinner who holds the house together, set aside even a few pence a week so as to go away and amuse herself alone? We deplore the scanty knowledge and appreciation that town and country people have of one another; what better way to cure this than the sending of town girls and women to welcoming country homes? Many of us have thankfully remembered all through our lives some kind hostess who invited us to stay, or some fairy godmother who paid for us to travel, the odious word "pauperizing" never being used in such a case. Why should not we who spend pounds on the vacations of ourselves and our families be allowed, and, indeed, urged, to spend shillings on the much-needed holidays of those who cannot pay for themselves? The summer months are hurrying by, and there is no time to lose. "Do it now!" On merely selfish grounds we would suggest that we should enjoy our own travels more this year if we preceded them by sending a donation to the wise, careful, old-established, and indefatigable Factory Girls' Country Holiday Fund. Subscriptions and donations will be thankfully received and acknowledged by the hon. treasurer, Mrs. Slater, or Miss Mary Canney, 75, Lamb's Conduit Street, London, W.C.1.

Disclaimer

Sir HAROLD GILLIES writes: In reference to an article in the *Evening Standard* of August 14th, in which my name is freely mentioned and an old photograph incorporated, I should like, through your columns, to reassure those members of the medical profession who are staunch defenders of its ethical position that not one single word on this or any other subject has been communicated to any representative of the *Evening Standard* by myself or either of my two secretaries. I wish to make it quite clear that this article and photograph were published without either my knowledge or consent.

Novocain and Cocaine

In a report of a recent inquest it was stated that novocain is a preparation of cocaine. The Saccharin Corporation, Ltd., the sole distributors of the former drug in this country, point out that it is not a preparation of cocaine, and that the latter does not enter in any form into the manufacture of novocain.

Section of Obstetrics and Gynaecology Correction

Professor F. J. BROWNE (University College Hospital) writes: Will you please allow me to correct an error in the report (*Journal*, August 11th, p. 266) of my remarks in the course of the discussion in the Section of Obstetrics and Gynaecology on "Ovarian Conditions as a Cause of Pelvic Pain." I did not say that pain was a common symptom of ovarian tumours, but only of malignant tumours. It was with this statement that Professor Dougal expressed his disagreement (p. 267).

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 29, 30, 31, 32, 33, 36, 37, and 38 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 34 and 35. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 156.

BRITISH MEDICAL JOURNAL

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION

LONDON: SATURDAY, SEPTEMBER 1st, 1934

EDUCATIONAL NUMBER, SESSION 1934-5

THE TRAINING OF THE MEDICAL PRACTITIONER

BY

SIR HENRY BRACKENBURY, LL.D., M.D.

Medical education, like all other education, is a co-operative business. The idea that even the infant mind is a *tabula rasa*, a clean slate on which the parent, the teacher, environment in general, may write what it will, has long since been discarded. But even the infant mind, conditioned, as to the impressions that may be made upon it, by the biologically inherited number, character, and connexions of the brain cells, is not a passive instrument, but, at least after those first few months of extrauterine life of which we really know so little, progressively takes a larger and larger part in itself determining what impressions it will receive and how it will react to them. By the time adolescence is reached nature and nurture, especially the deliberate discipline of the schools, have produced or disclosed limitations, of a greater or less degree of severity, so that, with regard to all subsequent education, whether of a general or of a technical character, the contribution of the student is of at least equal importance to the contribution of the teacher. In medical education, as in other spheres, this is sometimes forgotten, or at least not always given its full emphasis, and it is by no means uncommon, when the result is not conspicuously successful, for the teaching to be blamed when the student is at fault, and vice versa. The consideration, therefore, of what these respective contributions ought to be should be of substantial value and importance. Though their formulation and definition is not easy, and though others might prefer to set them out quite differently, the attempt may be worth making. The contribution of the medical school may be considered first, and then the contribution of the student.

Guidance by the Medical School

The first function of a medical school or faculty is that of *guidance*. Its performance is sometimes lacking. It is true that in all medical schools a proportion of the students will have fathers or near relations who are themselves members of the medical profession and from whom it may be supposed that a considerable degree of guidance will have been, and will continue to be, forthcoming: but even in these cases the responsibility of the school is not removed, and in the case of those students who in this regard are not so fortunately placed, the lack of guidance may even, in greater or less degree, spoil a whole career.

The main guidance required, either at the beginning of studentship or at a later period, is, of course, as to the qualifying examinations which should ultimately be

taken; the order and proportionate emphasis which, in the case of each student, should be given to the various parts of the course leading up thereto; and the particular branch of professional work or post-graduate study upon which it seems most appropriate or advisable for the student to enter. This is a responsible task, and naturally requires close attention to individual characteristics and abilities. It may be held to be one of the most important duties of the dean of the school or faculty.

Another direction in which guidance may reasonably be expected from every teacher is in the prescription and supervision of private reading and of library and museum study. Further, the medical course is so full and at first so bewildering that the student requires to be given a sense of perspective. In the words of the Report of the British Medical Association on Medical Education,¹ he

"should not be left in the dark as to the plan which is being followed by a teacher of a subject, as to what are the outstanding problems with which a subject deals, and as to the place which these problems occupy in the general scheme of medical learning."

The Student's Objective

Guidance in these various directions cannot have its full value unless there is agreement as to the objective. To the generality of students this objective is the early entry upon general medical practice. For others, before the course is completed, it becomes definitely a preparation for further study leading to practice in some special field. For a few from the beginning this ultimate intention is a fixed goal. The second of these classes may require guidance with regard to some prolongation or modification of their years of clinical study; the third class may be directed in such prolongation or modification at an even earlier period. It is, however, generally held in this country that even for those who propose to engage in a special branch of practice, a common course of study intended primarily as an introduction to general practice, and even a relatively short experience of such practice, is the best of preparations.

This view is not universally accepted. In America and elsewhere, where a large proportion of the students have the avowed intention of work in a limited field, the medical schools have tended to adapt their courses to such ends. To-day, however, there is pronounced reaction from such undue specialization, both in practice and in education, and the members of the American Com-

¹ *British Medical Journal Supplement*, April 21st, 1934, p. 192.

mission on Medical Education unite in deprecating the fact that "a large proportion of recent graduates limit their practices to a specialty often without a sufficiently broad previous clinical experience." The objective of the ordinary medical course may, then, be accepted as being correctly stated in the initial paragraph of the British Medical Association's report:

"The primary object of the medical curriculum should be to produce on its completion a practitioner who has acquired a right attitude towards professional duties and responsibilities, an ability to deal reasonably in the early days of practice with such patients and conditions as may confront him, and such basic knowledge and mental training as will enable him to profit continuously by daily experience. It should at the same time constitute such a co-ordinated course of study as will, by its mental discipline, make the student a really educated person and not merely a skilled technician."

Lack of Co-ordination in Teaching

No doubt the main function of the medical school or faculty would be commonly stated as that of giving instruction. The difficulties in the way of its complete and perfect performance seem to arise from two facts. One of these is that the qualities necessary in a first-rate teacher are not invariably combined with those required from an expert in one particular subject or in a first-rate laboratory worker, research worker, or clinician; and it is for the possession of these latter qualities that many members of the staff of a medical school, or the hospital connected therewith, are primarily appointed. The other fact is the immensity of the field of knowledge that has to be covered and the impossibility of dealing with more than a relatively small portion of it in the time at disposal.

It is from these two facts, neither of which is completely remediable, that most of the recently expressed complaints as to the inadequacy of medical education arise. If the efficiency of the teaching of the various subjects of the curriculum is grossly unequal; if each subject is regarded as a largely independent section of study; if, as would then be natural, each teacher aims at imparting to the student as much knowledge of his own subject as is possible in a given time; then the student may, indeed, pick up a considerable amount of useful knowledge, and this may even be such as will enable him to pass the necessary examinations. Yet it is certainly not "a co-ordinated course of study," and must leave at least an appreciable number of the students very imperfectly equipped as medical practitioners capable of profiting fully and "continuously by daily experience." This truth is recognized by the authorities of every medical school: it does not everywhere find an application in the regulation of the actual teaching.

The remedy is to concentrate upon the general course and not upon particular subjects or sections of the curriculum; to bear in mind the limited nature of the immediate objective at which the course is aimed; to select the team of teachers with great care, and not to restrict each teacher too narrowly to some special portion of the curriculum, but to make use of him in any part thereof to which he can usefully contribute.

Need for a Widened Outlook

There is a rather different aspect in which the instruction given in some medical schools is said, not without some reason, to be wanting. Even if the teaching be uniformly excellent, fully co-ordinated, and purposefully restricted it is possible that it may be presented from a point of view which takes too limited a cognizance of certain conditions with which the student will be confronted almost from the moment that he enters upon practice. He will be concerned with human personalities, not merely with the cadaver or with bodies exhibiting

some pathological process; with the prevention of disease and the promotion of health; not merely with the cure of illness; and with man as a social unit in all sorts of untoward surroundings, not merely with a patient within the narrow bounds of a hospital. The public has become greatly exercised about these things. Hence arises the insistent demand, not yet fully met in any medical school, that teaching should be throughout more largely on the living body, and have regard to the mental as well as the physical; that the preventive and constructive aspects of medicine should permeate the whole course; and that medicine should be presented as a social agency taking its proper leading place among others.

Variety in Teaching Methods

This leads up to the methods of instruction, which need some consideration. Many methods are employed in all schools—lectures, demonstrations, dissection, laboratory work, discussions, controlled reading, supervised clinical duty, what is called (particularly in America and Germany) the "seminar," and so on. There is a tendency for one of these methods, associated with those others most closely allied to it, to become predominant in different countries. Thus Mr. H. S. Souttar, in the *Educational Number of the British Medical Journal* two years ago, writing with special reference to clinical instruction, describes the German method as demonstration; the French as attendance; and the English as apprenticeship. These differences, though real, are tending to disappear; and in each of the above-named methods there may be numerous modifications. This variety, whether in different countries or in different schools within the same country, is a good thing. In medical education, as in other education, stereotyping is fatal: a strict uniformity, either in time, order, or method of instruction is strongly to be deprecated. Sir Norman Walker, in his presidential address to the General Medical Council in May last, said: "It is not possible to frame a model curriculum which will suit every country or every school in any country, and no hard-and-fast arrangement of subjects is possible, even if it were desirable"; and the British Medical Association's report states that "it is desirable to allow—even to encourage—a wide liberty of choice in the different schools, provided that certain broad general requirements are satisfied."

Lecture Theatre and Laboratory

There are, however, two of the methods of instruction ordinarily employed upon which particular comment may be made. The systematic lecture course has been paramount in most schools perhaps too long. It is a survival of the days when good textbooks did not exist or were not easily come by, and when habits of speaking and hearing varied widely from those cultivated or common to-day. In Elizabethan times, and in the seventeenth and eighteenth centuries (as particularly illustrated in the spheres of the stage and the pulpit) the English people possessed a range and dignity of speech and a power of attentive and appreciative listening which to-day they have largely lost. Even in Scotland it is not what it was. Yet the spoken word, even in a set discourse, still has its value; and, as Sir Clifford Allbutt said in his address on professional education nearly thirty years ago, "reading of textbooks at home is eating sawdust." The opinions of the modern student as to the limitations of the value of lectures are worth noting, and may perhaps be a better guide than those of the lecturers themselves. In a report recently issued by the Manchester University Medical Students' Representative Council it is held that "most necessary changes" are that "systematic lectures should be drastically reduced in number," that "attendance at all lectures should be voluntary," and that

"where lectures must be given, then the function of the lecturer should be: (a) to present a view of the subject as a whole; (b) to state principles and so give coherence to the subject; (c) to bring textbooks up to date; (d) to emphasize the salient points in the textbooks by illustrations from the lecturer's own experience; (e) to vitalize the subject."

Laboratory practice is in some danger of usurping the place of undue prominence which is being vacated by the set lecture. It has a very important place; but it is time-consuming and is quite often directed to wrong ends. It is probably unnecessary to say more than that many laboratory experiments frequently carried out are relatively unimportant and uninforming, and that, in the words of the American Commission on Medical Education, "the laboratory is used too much as a training in manipulation rather than as a means of illuminating and illustrating the subject-matter and familiarizing the student with some of the general principles and methods."

Learning by Doing

The third important function performed by the medical school is the affording of *opportunity*. It has been said that only a small portion of medicine can be taught to the student; the best that can be done is to enable him to learn; and it is a commonplace that, in some directions at any rate, the best way of learning is by doing. The way to much effective knowledge by the medical practitioner lies along this path. In the Bulletin on Medical Education of the Health Organization of the League of Nations it is said that "several countries complain that the majority of students look and listen but do not act. They remember what they have seen and heard, with their heads, but not with their fingers."

It is the possibility of the adequate performance of this function of affording opportunity that should be a determining factor with medical schools and faculties in admitting students. The number of students may, in respect of opportunity of learning, easily become excessive. With regard to lectures, demonstrations, class teaching, the numbers, within fairly wide limits, do not matter, but when they affect the easy securing of parts for dissection, the actual performance of suitable laboratory experiments, the possibility of making the required number of post-mortem examinations or of maternity attendances or of anaesthetic administrations, the gathering of a sufficiently wide experience during clerkship or dressership, or the securing of clinical assistantships or house appointments, then the actual number of students accepted, and the proportion of hospital beds and of outpatient attendances to such number, become of the utmost importance. If the numbers are properly adjusted it should be possible for every student to have practical experience in the performance of all those minor operative procedures, whether clinical or pathological, whether medical, surgical, or obstetric, which will be essential for him in the carrying on of his daily practice after qualification. Seeing these things done by others is not enough; it is essential that he should have actual experience in their practice. Having been done once or twice under supervision they no longer present the formidable aspect which has in many cases prevented some medical practitioners ever attempting them. Yet a practitioner's equipment is awkwardly and inconveniently incomplete without this skill.

Clinical Experience and Responsibility

The student needs to be afforded opportunity not only for gaining clinical experience and acquiring manual skill, but for realizing and exercising a sense of responsibility. In this respect the average student in Great Britain and Ireland is already in a relatively better position than

the ordinary student elsewhere. The requirement of the periods of clerkship and dressership gives him this advantage; but the opportunities so afforded are not always as full as they might be. The responsibility placed upon clinical clerks and surgical dressers varies very considerably.

Further, in regard to actual practice, it is perhaps a little curious that the only specific numerical requirements of the General Medical Council with regard to the personal performance of duties while a student are concerned with post-mortems, maternity cases, and the administration of anaesthetics. It is no doubt assumed that wider opportunities will be given and wider responsibilities undertaken during the holding of a clerkship or dressership. Nevertheless it remains true—and this must be to some extent inevitable—that on qualification the student has not acquired self-reliance or an adequate sense of responsibility, and is, indeed, very imperfectly instructed in the nature of the responsibilities which then fall upon him. It is for this reason that the American Commission insists so strongly upon the importance of the "internship," and that the British Medical Association's report suggests for every student a final clinical period of from six to nine months after the main part of the qualifying examination has been passed. This period, involving a maximum amount of clinical experience and responsibility under supervision, would usually be spent either in a definite appointment to a hospital department or clinic or as a pupil to an approved general practitioner or medical officer of health with a sufficiently wide range of services under his control. With this would be combined specific instruction in the legal, ethical, and social obligations of a medical practitioner. The difficulties of carrying out such a suggestion are obvious, but they are probably theoretical rather than actual, and can certainly be overcome by good will and judicious selection. Of the importance and value of such an experience on the threshold of independent practice there can be no doubt whatever, and of the real necessity of some such experience at this stage nearly all observers and critics of medical education are quite convinced.

The Imponderables

The last function of a medical school or faculty that need be mentioned here is that of *inspiration*. It must be a poor school or university which cannot supply this, either through its general atmosphere or through the personality of one or more of its teachers. It is a real thing, and a necessary thing for the medical practitioner. Without it the student's acquirements will be imperfect, and his work, both during his studentship and thereafter through his professional career, a burden, or at least a source of infinitely less satisfaction than it might otherwise have been. In the words of Littré, "La puissance de l'éducation consiste à augmenter le nombre des motifs dans l'esprit de l'individu." If the student is not put in the way of acquiring, or of developing, some width of culture, a zest for knowledge, a love for his work, a real sympathy with human suffering and trouble, a profound respect for confidence reposed in him, an appreciation of nobility of character and of the dignity and peculiar requirements of professional life, to that extent will the contribution made by the medical school to his medical education have failed of its complete purpose, and to that extent will he pass out from it a liability rather than an asset to his profession and to the community.

The Student's General Education

As was said at the very beginning of this article the contribution to medical education that must be made by the student is no less important than that made by the

medical school or faculty. The contributions to be expected from the student may, however, be considered much more briefly than those required from the school, for, except with regard to the first of those about to be mentioned, they lend themselves much less readily to analysis or to detailed criticism.

The first, and very important, contribution from the student must be an adequate *previous equipment* in knowledge and intelligence. There can be no reasonable doubt that the minimum of present requirements in this respect is definitely too low. This minimum level should be appreciably raised, and the present is a convenient time for effecting this improvement, as the rate of entry into the medical profession might be somewhat reduced without any public loss. No profession should be entitled to claim the epithet "learned" more surely than the profession of medicine. It has an enormous responsibility to the public. It possesses the confidence of the public, to an extraordinary extent from individual members of the community, and to a great extent from the community as a whole. It exercises, therefore, a very considerable degree of authority over public thought, and great influence over many persons. The medical practitioner by reason of this should, as is said in the League of Nations Bulletin on Health Education, in the best sense of the words, "belong to the élite. His professional knowledge should be enhanced by general culture." Yet this does not universally obtain. It cannot be denied that there is a small substratum within the profession of whom this is far from being true, whose general education can only be described as poor, whose interests are extremely narrow, and a few of whom seem incapable of realizing or appreciating fully the obligations of professional life. It is only three years ago since the following was written:

"Our students are the most uninteresting of men. They are ignorant of either art or literature. They only read sporting papers and cheap magazines. They do not even know their own language, nor can they spell. They are in fact semi-illiterate."

That is American, and is not true of this country, even of a small minority of students; but it illustrates very vividly the dangers of too low a standard of general education being allowed to qualify for admission to the medical course. Exactly to what degree or in what particular direction the minimum standard should be raised may be a matter of controversy, and there should certainly be a wide range of choice in the subjects that may be taken; but it is not unreasonable to suggest that at least a pass in something roughly equivalent to the intermediate arts examination of a university is not an unduly high requirement as a test for entry upon the profession of medicine.

Scientific Groundwork

There is a common agreement that the preliminary equipment of the medical student should include a training in science, and that this training should embrace not merely a suitable grounding in physics and chemistry, both inorganic and organic, but also in the principles of general biology. The biological approach to medicine is essential—should now, in fact, be regarded as axiomatic—and is becoming more and more important each year. No very profound knowledge of these sciences need be looked for at this stage—nor is it a *sine qua non* at any stage—but an understanding of their principles, methods, and main elementary facts cannot be dispensed with. Nor does it matter where, or exactly at what stage of previous education, such understanding is obtained. It may easily be acquired, along with some other studies, during the two years following the passing of the School Certificate

examination, or its equivalent, at many schools, or as part of a general course at some university or university college; but it should be required to be completed and tested prior to the commencement of the fifty-seven months of the medical course proper. In the words of the British Medical Association's report:

"The student should then at least know how to think, how to read with comprehension and reasonable fluency one language besides his own, and how to express himself, both in speech and in writing, logically and clearly in his own language. He would have been introduced to some great literature, and have some notion of historical sequence and perspective. He would understand scientific method and scientific principles of observation and deduction; and he would have acquired such a knowledge of the main facts or problems of the physical universe and of living organisms as to enable him to pass to the study of the human organism and its environment with interest, intelligence, and profit."

Without some such previous equipment the student will certainly be unable to complete his medical course within the prescribed minimum period, will be unable to profit fully by the sequence of studies undertaken in that course, and will thereafter remain lacking in some of the mental content and quality which would enable him, with increasing experience, to render the complete complement of service. For these things, if not taken in their proper place, cannot so well be supplied thereafter, and will probably not be supplied at all.

Habits of Work

A second contribution which the student may be expected to make to his medical education may be described as *assiduity*. This is defined in the *Oxford English Dictionary* as "constant or close attention to the business in hand, unremitting application, persistent endeavour, perseverance, diligence." Too much, of course, cannot be expected of the youth of 17, 18, or 19 years of age. He comes, probably, fresh from his secondary or public school, where he has been accustomed to his weekly and terminal holiday, possibly with some small task in which he can occupy some of his leisure not unpleasantly or unprofitably. In his early years of medical study it is likely that he will expect a continuance of similar conditions, and may be able to contrive them. But in his later clinical years he will become more conscious of the life in front of him, and will realize that the necessities of his work require him to put in six days work a week instead of five, and make his working year one of nearly twelve months instead of little more than nine. Assiduity, in the full meaning of the word, will, indeed, be required of him if he is to complete his course in the five years or so in which he may hope to accomplish this in the absence of illness or other misfortune. This is no bad preparation for the conditions of life in a successful general medical practice; and the exigencies of clerkships, dresserships, and other time-limited duties will make the taking of regular vacations at stated periods impossible. In fact, the normal vacation times may be found among the most profitable opportunities for a more extended clinical experience. At any rate, the average student must expect to make his contribution along these lines by an increasingly strenuous period of steady, but, it is to be hoped, not disagreeable work.

A third contribution to be made by the student is *character*. It is often circumstances rather than inclination or special aptitude that lead to the choice of a career. It is a very fortunate thing when all combine in the choice. It has to be recognized, however, that there are some persons whom no amount of educational endeavour on the part of the teaching staff of a school or university could convert into accomplished and successful medical practitioners. There is not necessarily any question here

of goodness or badness, but merely of suitability. It is not always the most learned physician who makes the best medical adviser. In general, however, it is only very rarely that anyone entirely unsuitable finds his way through the medical curriculum; and there are, of course, within limits, different kinds of suitability for different branches and crafts within the profession. It remains true that, though character may develop under the influence of educational surroundings even after adolescence, and though this influence may be beneficial, it is the student and not the teacher who must contribute those qualities of character, whether inherent or acquired, which will make or mar the success of his career, whether during his student days or thereafter; and it is a contribution which, to a large extent, he must deliberately and consciously make.

Conclusion

Thus the medical school or faculty offers guidance, but very often this cannot well be given unless it is sought,

and though the wisdom of such guidance remains with the teacher its acceptance or otherwise depends upon the student. The school offers instruction, but the student may neglect, or even avoid, it; and offers opportunity of which the student may or may not avail himself. The school offers inspiration, too; but without a basis of character to work upon it loses all its force. Medical education is a co-operative business.

It is a continuous business also. It begins, in a sense, before the student comes to the medical school. While he is there, though it has the definite and limited aim of equipping him to enter upon practice in five or six years, it should also be laying sound foundations on which later post-graduate and continuing education can be built. Afterwards, while in practice, the medical practitioner must go on learning and keep his knowledge up to date. His medical education should not cease as long as he lives, or at least until he no longer practises his profession.

THE PROFESSION OF MEDICINE

INTRODUCTORY

In accordance with long-standing custom we preface the main contents of the annual Educational Number of the *British Medical Journal* with some remarks by way of guidance to those who contemplate entering the profession of medicine. What is said here will follow the lines laid down in previous years; but readers of each subsequent section should bear in mind that not only the methods of medical education but even its purpose are under close scrutiny in various responsible quarters. The medical curriculum is a subject of discussion to-day in nearly every country of the world.

In our Educational Number last year (September 2nd, p. 409) we referred to two important reports on medical education then very recently published—the final report of the American Commission and the interim report of the British Medical Association's Committee. The final report of this committee has now been endorsed by the Council and Representative Body of the Association, and within the year there has also been issued a Bulletin on "Medical Education and the Reform of Medical Studies" under the auspices of the Health Organization of the League of Nations. These three publications—American, British, and international—are probably the most important pronouncements on the subject of medical education that have been issued for many years, and they must together have great influence in determining any changes which may be made either in Europe or in America as a result of the widespread consideration now being given to the matters with which they deal.

The point of view of each of these documents is naturally different from that of the others; but the correspondence of their conclusions and suggestions is remarkable: indeed, in the case of the reports of the British Medical Association and of the Health Organization of the League of Nations they may, with scarcely any exaggeration, be said to be identical. Broadly, the different aspects from which the three reports consider the subject may be indicated by the questions. What are the needs of the public in relation to the supply and equipment of doctors? (American.) What sort of medical practitioner is it desired to produce? (British.) What is the field of study which must be covered, and how best may this be done. (International.) It must, however, be understood that none of the reports is confined exclusively to answering only one of these questions. All alike insist on the need for a higher general culture and a wider knowledge of scientific

(especially biological) facts and principles in entrants upon medical studies; on the importance of medicine as a preventive and social agency; on the co-ordination of medical studies into a unified course instead of their treatment in separated departments; and on the absolute necessity of increasing the opportunity for practical clinical work and the cultivation of a sense of responsibility. In the American report and the League of Nations Bulletin will be found a relatively full account of the actual curriculum of studies in different countries. The impression left by a careful consideration of these is that, for the generality of students, the courses of study prescribed and followed in Great Britain, though in need of revision with a view to meeting more fully the conditions above referred to, are, in most respects, the best to be found anywhere. In his presidential address to the General Medical Council in opening its last summer session, Sir Norman Walker said:

"Medical education and its bearing on the public weal is to-day the subject of anxious consideration in every civilized country. . . . The boundaries of medicine are ever extending, and there is more and more to be learned. The Council welcomes all the inquiries which are going on as likely to contribute to the solution of a difficult problem."

The General Medical Council has already appointed a small Curriculum Committee to give preliminary consideration to such reports and observations on the subject as may be brought to its notice, and in due course, no doubt, the fruits of this consideration will appear.

FINGER-POSTS

The first object of the Educational Number, 1934, is to inform prospective students and their parents of the steps that must be taken in order to become a registered medical practitioner under the existing order of things. The second is to assist those wishing to know what a medical career has to offer, and others who, having already decided to study medicine, are uncertain about the line of work for which they are best suited. This introductory article is meant to serve as a clue to the great body of information contained elsewhere, but it also gives an opportunity of touching upon some aspects of medical study and practice, and of directing attention to a few points that might not occur to anyone without experience of the medical life.

Intending students will find in the pages that follow an account of the course of training required of them at the

present time, the places where it can be obtained, and the bodies which test the knowledge gained and confer degrees or diplomas entitling successful candidates to become legally qualified medical practitioners. Sections are included also on post-graduate study, on the higher qualifications, both general and special, and on most of the varied spheres of work open to registered medical men and women at home and abroad. The details given are founded on official information, and arranged along the customary lines.

PORTALS OF THE PROFESSION

The *Medical Register* is the official statutory list of legally qualified medical practitioners kept by the General Medical Council. There are many ways in which admission can be obtained to the *Register*. No fewer than twenty-seven bodies—eighteen universities and nine corporations—either separately or jointly, issue registrable qualifications, and the number of teaching institutions is even larger. Nevertheless, the medical courses of the various universities and schools in Great Britain and Ireland run on parallel lines, and the obligatory curriculum is much the same for all students. But the individual teaching and examining bodies have different standards and requirements and bestow different qualifications, and the choice should therefore be made early, so that a definite plan may be followed. The possession of a university degree is generally regarded as an advantage in practice, yet a considerable proportion of medical men in this country find themselves debarred from obtaining it because the Conjoint Examining Boards formed by the union of medical corporations have no power to grant degrees. The decision to study for a university degree in medicine should, if possible, be made by the time a boy or girl is 15. A matriculation examination or its equivalent should be attempted without delay, and the parent should ensure that the special requirements of the medical faculty of the selected university are fulfilled. Few head masters or housemasters seem to be adequately informed about medical requirements under the curriculum as readjusted by the General Medical Council in 1922, and it is doubtful if all secondary schools are fully competent to meet the varying requirements of different authorities. Parents should therefore make inquiries on their own account in order that valuable time may not be wasted during the last year or two at school.

The conditions with which those who wish to enter the profession must comply are regulated by the General Medical Council; which is a statutory body set up under the Medical Acts; a summary of its functions and requirements is given at page 391. Every student, after passing examinations in the subjects of general education and in the preliminary sciences of chemistry and physics, must take a course of training at a recognized medical school, covering a period of at least five years, but usually extended to six years or more.

Examination of candidates as to their fitness to practise medicine, surgery, and obstetrics is left to the licensing bodies, which are of two kinds—the universities, and certain medical corporations in England, Scotland, and Ireland. The requirements of these licensing bodies are summarized elsewhere under separate headings. One of the functions of the General Medical Council, besides that of keeping the *Medical Register* and maintaining discipline within the profession, is to make sure that the tests at each stage do not fall below a certain standard and that the students examined have undergone prescribed courses at approved institutions. Successful candidates eventually receive either degrees, in the case of a university, or diplomas or licences, in the case of a corporation; these qualifications entitle them to claim insertion of their names

on the *Medical Register*. Every student, as soon as he obtains his qualification to practise, should at once register; otherwise he cannot hold a public medical appointment, or sign any certificate required from a legally qualified practitioner (such as a death certificate), or recover professional fees in a court of law.

COST OF MEDICAL EDUCATION

For the ordinary student the outlay on his professional education resolves itself into the cost of training at medical school and hospital, and the cost of living during the five or six years of undergraduate study. Besides differences in the charges made for instruction there are differences in examination fees, as well as in the fees for certificates of qualification, and those who seek the higher degrees and diplomas must expect to pay more for the additional courses and tests and certificates. Again, not all students have the knack of imparting what they know to an examiner, and every setback due to failure in the examination room or to illness means added expenses. School and examination fees, together with the cost of board, lodging, clothes, and recreation, form the largest items, and to these must be added the money spent on books, microscope, instruments, and so forth.

Since professional education must continue for five years at least (a period exceeded by the vast majority), and since the cost of living varies much in different parts of the country, while personal expenditure varies still more, it can only be said in a general way that anyone who thinks of entering the profession should be prepared for an outlay of at least £1,500. Something between two-thirds and three-quarters of the whole amount would probably be spent on maintenance, and the rest in fees, etc., for tuition and examination. The fees charged by the different schools and licensing bodies are stated in the paragraphs relating to each on other pages of this issue. When making an estimate of the probable outlay, the many helps available nowadays for the reduction of expense should not be ignored. At nearly all the medical schools more scholarships and money prizes are offered now than in the past; at the Scottish universities bursaries are numerous; and the Carnegie Trust (whose regulations are summarized at page 404) gives pecuniary help to many Scottish students. The main thing to bear in mind when considering costs is that, as compared with other professions, the period of training in medicine is long, and for most students expensive. Further guidance on this matter will be found in a memorandum,¹ drawn up by the late Registrar of the General Medical Council. This pamphlet gives much useful information, including a comparative table of the cost of study and examination at the various institutions.

NUMBERS OF MEDICAL STUDENTS

The following brief survey should be read with the notes and tables printed at page 389 on the numbers of registered students and practitioners. More new students mean more new doctors five or six years later, though, as the chart shows, there is a fairly constant wastage.

At the close of the last century the annual entry of medical students in the United Kingdom had been on the average about 1,800, and then for the next thirteen years it stood at about 1,400. During the war period, though many students left to serve with the Forces, the entries grew steadily larger, so that in 1918 they were 2,253, and in the following year, when demobilization was in active progress, they reached 3,420. In the next five years the numbers rapidly fell, but from 1923 to 1928 they

¹ *Memorandum on the Procedure to be Adopted by those who desire to enter the Profession of Medicine, with Notes on Costs and Prospects.* General Medical Council, 44, Hallam Street, Portland Place, W.1. Price 1s. post free.

remained at a fairly steady level rather below the immediate pre-war average. In 1929 the entries rose again to 1,502, and in 1930 to 1,792. In 1931 they were 1,643, in 1932 they were 1,947, and last year they were 2,287, the highest figure since 1920.

In the past fourteen years the numbers of new practitioners registering each year have greatly exceeded the usual pre-war figure of eleven hundred or so. The large additions to the profession in recent years brought the total number of names on the *Medical Register* up to 56,741 at the end of 1933. This is 8,600 more than the figure for 1923, nearly fifteen thousand more than that for 1913, and nineteen thousand more than that for 1903. The population of the British Isles has not increased at anything like that rate during the same decennial periods, and the ratio of doctors to inhabitants is therefore much higher now than ever before. Some think that the saturation point has been reached. We should say rather that at the moment the medical profession of this country is quite large enough, but not so much overstocked as ill distributed. None the less, it is probably true of this country, as of America, that "doctors are being trained without any consideration of possible consumer requirements and beyond the limit that society can adequately support."

CHOICE OF CAREER

After registration there is usually a period of transition between pupillage and established practice. This time may be put to the greatest advantage by serving as house-physician, house-surgeon, or casualty officer in a hospital, by working as assistant or locumtenent in private practice, or by seeing something of the world as a ship surgeon. As a preliminary to practice of whatever kind, a year spent in junior appointments at a teaching hospital—"clinical experience under supervision"—is a most profitable investment.

If his mind is not made up already, the newly qualified practitioner has now to consider in which branch of the profession he can find a suitable outlet for his abilities. The choice is very wide, though the decision is often dictated rather by opportunity than by a nice balancing of tastes and talents. Among the great variety of paths open are general medical practice in town or country; Government service at home or abroad, including the medical branches of the Armed Forces; public health appointments and other administrative or official posts; institutional work, such as that of the municipal hospital, the mental hospital, the fever hospital, and the sanatorium; academic positions in schools of medicine; and special work in scientific research or in one of the many subdivisions of clinical medicine and surgery. Most of these careers are discussed in some detail in later sections, but a few words may be said here about general practice and the work of a consultant or specialist.

Further information about such matters will be found in the *Handbook for Recently Qualified Medical Practitioners*, published by the British Medical Association.¹ This comprises articles on openings for members of the profession; on practical aspects of medical work; on registration and the privileges of practitioners; on practice under the Insurance Acts; on post-graduation study and special diplomas; and on medical defence societies.

GENERAL PRACTICE

General practice is usually entered in one of three ways. The newcomer may take a house, put up a plate, and wait for work to come to him; he may buy the goodwill of a practice rendered vacant by retirement or

death; or he may become a partner in an established firm. The first is considered more risky than the second, and the second than the third. A well-managed partnership of three or more has this advantage over single-handed practice, that it allows each partner leisure for recreation and for keeping up with the progress of medicine. Success in private practice demands a great deal of knowledge beyond that gained at the medical schools, and hence a man is more likely to be accepted as a partner, or to do well on his own account, if he has already some experience as an assistant or deputy. Common-sense hints on how to embark on general practice, and on some of the pitfalls in the path of the beginner, will be found in a little book reviewed in these columns two years ago.²

The general practitioner cannot hope to be an expert in every department of medicine, but he should have a more comprehensive outlook than the man whose life is devoted to perfecting himself in the technique and minutiae of one subject. The opportunities he has of seeing his patients for minor ailments as well as for serious illnesses; his acquaintance with their family history, habits of life, social circumstances, and many other personal details learnt only after long and confidential intercourse, give the "G.P." just that knowledge which enables him to treat the patient and not merely the disease. All the more important, therefore, that the education of the general practitioner should be planned and carried out on right lines. The curriculum is already very long and it cannot be further lengthened. Courses of study and tests of competence should be rearranged so that the future practitioner's time is not spent in acquiring knowledge of small use in after life. The aim of his teacher should be to give him a solid foundation upon which he himself can build through experience and study after qualification.

Since three-quarters at least of those who pass out of the medical schools become "family doctors" sooner or later, it seems clear (though it is not everywhere admitted, even to-day) that the main purpose of the curriculum ought to be the training of the student for general practice—that is, the production of a "safe and competent general practitioner." This implies a sound knowledge of the needs of general practice—knowledge possessed only by those who have had personal experience of such practice.

"The general practitioner requires a specialized training no less than members of other branches of medicine, but while the greater part of the training for those branches is conducted by specialists in their own subjects, the formulation of our undergraduate educational policy, the training, and the examination are almost entirely in the hands of those who know little or nothing about general practice. I contend that, in order to achieve the real purpose of undergraduate training, the services of general practitioners of first-class ability, of considerable experience, and possessed of high professional and ethical standards should be enlisted in every medical school. In some places a beginning has already been made. Short courses of lectures to senior students on national health insurance practice, and here in Manchester the appointment of a well-known practitioner to the post of lecturer on medical ethics and conditions of medical practice, are welcome signs of at least a partial recognition of the claim of general practitioners to take their part in the task of undergraduate training."³

In its Proposals for a General Medical Service for the Nation⁴ the British Medical Association states as an axiom that "the medical service of the community must be based

¹ *A Guide to General Practice*. By A. H. Boothwaite. London: H. K. Lewis and Co., Ltd. 1932. (4s. 6d. net.)

on the provision for every individual of a general practitioner or family doctor"; and the whole series of proposals rests on this as a fundamental principle. In regard to the prevention of disease, on which the Association lays great stress in its memorandum, the general practitioner has an increasingly important part to play. As knowledge accumulates he should come more and more to study early disorders of function and the preservation of bodily and mental health in varying circumstances. While this is all to the good, it cannot be denied that encroachments on private medical practice are perpetually being made under the auspices of the State or of the municipality or of voluntary bodies, and that official requirements and administrative checks imposed by public authorities tend to increase.

The national system of compulsory health insurance, now more than twenty-one years old, has had a profound influence on general medical practice in this country. The Insurance Acts provide domiciliary medical attendance for some seventeen million persons, and more than 18,000 members of our profession undertake the medical care of this vast section of the community. Thus the bulk of the general practitioners of the country now give, in large or small measure, attendance and treatment under a system embracing almost the whole working population. These practitioners, by placing their names on the panel (or medical list), signify their assent to the terms of service set out in the Medical Benefit Regulations and other relevant provisions. Their interests are watched over by the Insurance Acts Committee of the British Medical Association, which is the executive body of the Annual Conference of Representatives of Local Medical and Panel Committees.

CONSULTANT PRACTICE

The term "consulting practice" comprises in ordinary usage the work of the general physician, that of the general surgical consultant or operating surgeon, and that of the gynaecologist and obstetrician. These are the three large divisions of consulting practice, as distinct from general practice, which, though they imply some restriction, yet call for a wide range of activity and outlook, in contrast with the smaller ambit of a "specialty" in the narrow sense. Of these main divisions the third is obviously the most limited, but on several grounds it can claim to rank as something more comprehensive than the other specialties. No sharp line can, however, be drawn between consulting practice and specialist practice. Most general consultants, whether medical or surgical, are specialists in some branch of their practice, and most specialists are consultants in the sense that their work largely comes to them through the recommendation of general practitioners, with whom they act (or should act) in a consultative capacity.

Success as a consulting physician or surgeon or specialist is hard to achieve, except by the aid of appointments to hospitals, particularly those with medical schools. These posts are much sought after, and the time of waiting for a vacancy may be long. It follows, then, that the would-be consultant, since he can scarcely hope at first to keep himself on his professional earnings, must either have private means or be prepared, by teaching or in other ways, to make ends meet. Competition in this branch of practice is very keen. Expenses are heavy, and the young consultant or specialist may have to go through a long period of training and waiting before he makes an income; but on the other hand success, when it comes, is liberally rewarded. The advantage to a consultant of some first-hand knowledge of general practice is not widely enough recognized. "I wonder," said the great American surgeon, Dr. W. J. Mayo, the other day, "whether the present tendency to enter the specialties directly from the

medical school without intervening conversion of knowledge into wisdom is wise."

In the larger industrial towns of the North of England there are many "general practitioner specialists" who combine ordinary panel practice with much surgical or other special work in well-equipped local hospitals which admit patients in different categories according to their means. Though the fees are small compared with those earned by operating surgeons and specialists in London, the work is by no means unremunerative.

Additional degrees and diplomas are important factors in securing election to the visiting staff of a large hospital, and a few remarks about them may be made here. Beyond the qualifications which admit to the *Medical Register*, most of the licensing bodies bestow higher titles after further tests. A considerable number of those who have graduated M.B. at a university, including many general practitioners, proceed later to the M.D. When applying for the post of physician to a hospital it is always useful, and may be obligatory, to hold also the Membership of one of the three Royal Colleges of Physicians, according to the part of the British Isles in which the hospital is situated. So, too, the Fellowship of one of the three Royal Colleges of Surgeons should be obtained by those seeking surgical appointments, and the degree of Master of Surgery is an added distinction. There are also diplomas in a growing number of special branches of work—such as public health, tropical medicine, ophthalmology, laryngology, radiology, tuberculosis, psychological medicine, and midwifery—which are superfluous for most practitioners, but may be useful or even indispensable for those who intend to devote themselves to one or other of these subjects.

FINANCIAL AND SOCIAL ASPECTS

"The choice of a lifework is determined largely by the conditions, opportunities, and social recognition provided by a given vocation." In medicine the pecuniary disadvantages are the long and costly training, the time of waiting after qualification before the practitioner can count upon an adequate income, and the heavy working expenses in proportion to gross earnings. On the other hand, medical practice holds out the prospect of a fairly certain income, with unrivalled opportunities for exercise of the intellect in the service of others. But those who think of adopting it as a career ought to understand that medicine is a path to fortune only for the few. Yet if from the financial point of view it offers to most men little more than a means of livelihood always at command, in its social and cultural aspects the outlook is far brighter. A doctor's life need yield to none in the matter of sustained and varied interest. His lot is unlike that of many whose business gives little scope to the higher faculties, for he lives in, and by, the exercise of intellectual powers. The steady improvement in the education of the practitioner has added much to his influence with the public, and has been a large factor in raising his social status during the seventy-six years that have passed since the General Medical Council was constituted under the first Medical Act. Medicine gives to those who follow it an honourable position. The well-educated doctor stands high among his neighbours, and is the friend and confidant of his patients. Many go further, and take part in the public life of their district; and this is as it should be, because the doctor's training and outlook are such as fit a man for leadership.

PROFESSIONAL ORGANIZATION

Individuals and isolated groups of doctors are always at a disadvantage when they try to defend their interests against organized bodies, whether these are Government departments, local authorities, or commercial companies.

In his daily work the doctor is well able to deal with the individual patient and the patient's friends, but he cannot stand up single-handed to outside organizations. Medical men and women must therefore band themselves together, and the first step after qualification should be to become an active member of the British Medical Association. Besides having behind him the machinery and the influence of a world-wide professional body, a young practitioner will find in the meetings of his local Division or Branch, and in the Annual Meetings of the Association, many opportunities for keeping abreast of new work and for friendly intercourse with colleagues. Another thing that no new graduate should fail to do is to join one of the societies which for a small yearly sum undertake individual legal defence of their members. The need for

protection may arise out of the first case attended in hospital or in private practice.

The British Medical Association was founded in 1832 to promote the medical sciences and maintain the honour and interests of the profession; a brief note on its constitution and activities will be found at page 454. This great Association, with Branches throughout the British Empire and a membership of 35,000, is the only body that can act for the profession as a whole and speak in its name. The record of a hundred years' work shows that vocational organization, wisely directed, can combine service for its members with service for the public. Every medical man and woman should try to take a share in some of the movements, scientific or social or political, with which the B.M.A. has identified itself.

NUMBERS OF THE MEDICAL PROFESSION

A Review of Fifty Years

In order to present a general view of the numerical strength of the medical profession during the past half-century we have extracted from the records and set down below in parallel columns the total number of names in the *Medical Register* on December 31st of each year, and the numbers added annually by registration between 1884 and 1933:

Numerical State of the "Medical Register"

Year	Names added in Year	Total No. on Dec. 31	Year	Names added in Year	Total No. on Dec. 31
1884	1,388	25,321	1909	1,143	39,818
1885	1,377	25,998	1910	1,062	40,483
1886	1,431	26,452	1911	1,042	40,913
1887	1,534	27,246	1912	1,157	41,439
1888	1,184	27,939	1913	1,168	41,940
1889	1,305	28,348	1914	1,433	42,378
1890	1,286	29,163	1915	1,526	43,225
1891	1,345	29,555	1916	1,292	43,481
1892	1,513	30,590	1917	1,134	43,819
1893	1,579	31,644	1918	1,077	43,926
1894	1,426	32,637	1919	1,322	44,510
1895	1,446	33,601	1920	1,457	44,761
1896	1,385	34,478	1921	1,760	45,408
1897	1,230	34,642	1922	1,983	46,476
1898	1,210	35,057	1923	2,482	48,140
1899	1,351	35,896	1924	2,796	50,035
1900	1,345	36,355	1925	2,570	51,738
1901	1,318	36,912	1926	2,120	52,614
1902	1,275	37,232	1927	1,941	53,769
1903	1,233	37,878	1928	1,656	54,336
1904	1,168	38,492	1929	1,410	54,870
1905	1,240	39,060	1930	1,490	55,291
1906	1,197	39,529	1931	1,572	55,604
1907	1,221	39,827	1932	1,545	56,096
1908	1,137	40,257	1933	1,543	56,741

The varying proportion of registered medical practitioners to population during the period under review is shown in the following table. This sets out the total population of the British Isles at each decennial census since 1881, and the number of names on the *Register* in the same year.

Proportion of Practitioners to Population

Year	Registered Practitioners	Population, British Isles
1881	23,275	35,241,482
1891	29,555	38,104,975
1901	36,912	41,976,827
1911	40,913	45,370,530
1921	45,408	47,148,505
1931	55,604	49,959,455

These figures show a steady increase in the ratio of doctors to population, which was accelerated during the years immediately following the war. Making allowance for the large number of registered practitioners living abroad and for those no longer in practice, the proportion

of doctors to population is a good deal more than one to every thousand. In the United States of America it is estimated that there is one medical practitioner to every 830 people. Japan, with a population of 84,000,000, has some 50,000 doctors. According to statistics published last year by the International Labour Office the country with the most medical practitioners is England, with 1 doctor to every 822 inhabitants, then come Norway, Italy, and Switzerland, with 1 doctor to every 1,067, 1,218, and 1,231 inhabitants respectively. In Hungary, Esthonia, Germany, Denmark, France, Holland, and Luxemburg

Numbers of Medical Students and Practitioners Registering 1908 to 1933

the proportion ranges from 1 to 1,290 to 1 to 1,556, Belgium and Sweden have 1 doctor to 2,344 and 2,744 respectively, while in Bulgaria, Poland, and Yugoslavia there is 1 doctor to every 3,059, 3,332, and 3,568 inhabitants respectively.

Registration of Students and Practitioners

The relation between the numbers of new students and those of newly qualified practitioners during recent years is shown in the chart on this page, compiled from returns published by the General Medical Council.

The figures for the registration of practitioners year by year apply only to those whose names were entered on the British list, entries in the colonial and foreign lists of the *Medical Register* being excluded; hence the slight discrepancy between the totals indicated in this chart and those given in our tables printed above. Some further remarks on the numbers of medical students in recent years will be found in our introductory article on the profession of medicine.

ON CHOOSING A MEDICAL SCHOOL
A STUDENT'S VIEW OF LONDON TEACHING
HOSPITALS

A correspondent, knowing the interest now taken in all aspects of medical education, has lent us the MS. notebook in which a young friend recorded and analysed his impressions after visits of inquiry, made two or three years ago, to a number of London teaching hospitals and Continental clinics. The writer of the notes had, we learn, just finished his undergraduate career at one of the ancient English universities, and the main purpose of his tour was to help him in deciding where to enter for the clinical years of the curriculum.

After visiting nine of the twelve teaching hospitals of the metropolis he recorded his observations on an orderly plan. First, he drew up a schedule of the essential features of a teaching hospital in respect of what it should, in his opinion, offer the student who means business and aims high. He next considered each of the nine hospitals, individually and in some detail, from this point of view. He then formulated his conclusions in general terms, following this with brief notes on the special points of the hospitals under review. Lastly, he made a summary and comparison of the various institutions, awarding points to each on a uniform plan, and added up the total scores on the final sheet. Which hospital he chose, and why, we must not reveal.

The notebook as a whole brings before our eyes the picture of a young man of parts, possessing a methodical mind, acute observation, critical and analytical gifts above the ordinary, and a shrewd and unsentimental-eye for realities. His impressions and reflections were written purely for the purpose of helping him to make a personal choice, and the remarks on individual hospitals are much too frank for publication. With the author's consent, however, we reproduce below his "general conclusions" and his "essential features," in the hope that they may perhaps serve as food for thought, both to some of the younger generation whose professional training lies before them, and to those of riper years who are still pondering over the problems of the curriculum. Beyond one or two trifling corrections, we have made no change in text or schedule.

Factors Influencing a Choice

The ideally inclined, making a tour of the London teaching hospitals, is almost certain to be disappointed. Having associated hospitals with orderliness and spotless efficiency, and entering a building which is grimy, irregular, and unlovely on the outside, he wanders about in dingy corridors and peers into vast, hall-like chambers where hordes of sickly individuals are herded in archaic iron beds, and is appalled. "Is this Medicine?" he asks himself; and as he is led down miles of these dreadful passages and invited to gaze upon similar collections of recumbent beings, he becomes divided in his mind. Either these hospitals are hopelessly inefficient and patients recover by miracle, or medicine works in peculiar ways. Neither of which is correct.

That hospitals may be inefficient is certainly possible; also it is true that some features of medicine are definitely odd, but the point is that *medicine*, if one can speak of it as an entity, is mostly invisible in its process. It exists as an unseen process of repair in human bodies, as hypotheses or intentions in the brains of medical men, as a memory or instructions in the cortex of assistants, pharmacists, and nurses, and at only a few rare points when a physician does its application become visible—as when a physician is seen by a bed entrapping heart sounds in his stethoscope, a surgeon excising some offending organ, a patient about to swallow his physic. The rest is occult; enacted behind the scenes.

And if one can learn little of the way in which medicine is done by seeing over a hospital, how is one to judge of the hospital itself? Furthermore, if a place is chaotically ramshackle and desperately disorderly, one must always remember that few of the great discoveries of science have been made in light, airy, shining labs. Is a patient, also, any less likely to get better in an iron bedstead than in a chromium-plated one? Even more relevant: would one learn more from a patient who died in a hospital which looked like an industrial chemical laboratory than from one who spent his last hours in a place like a parish hall? Discrimination becomes more perplexing.

Perhaps one can gain a better perspective of the matter if one regards a hospital as an elaborate and intricate instrument for treating the sick. Regard the staff of the hospital collectively as the craftsman who manipulates the implement. If he is a conscientious craftsman he will take care to have the most effective accessories to his apparatus, and replace them when they become obsolete. Thus there is something fundamentally more progressive about a place which is kept up to date, designed to require a minimum of effort in its working, and fitted with the latest appliances, than about one in which these amenities are lacking. For a good workman does not tolerate bad tools.

If this much can be deduced from a single hospital, then how are several to be compared? Granted that one is to prefer a well-equipped building to a building worse off, one must not let the mere fact of obvious efficiency blind one to some other features of the place. The essential consideration is that one wants to learn medicine, and it may be (to revert to the simile) that while not paying as much attention to the appearance of his instrument as his colleagues, the craftsman is a better instructor of his apprentices.

Here occurs another difficulty. Unless one has actually sampled the methods of teaching at a hospital and experienced the results, one is not in a position personally to criticize; one can only judge from what is told by others (and opinions differ widely), or rely on one's own intuition (whose accuracy is equally questionable). There are certain features upon which a decision can be reached by use of mere common sense. If one is to learn, there must be material to learn from. Thus one would not be well advised in going to a hospital which had an enormous number of students in it but very few beds. And there must be teachers: it is reasonable to suppose that a man can more effectively teach a few students than a huge band of them. So that one can infer something as to the opportunities for learning at a hospital by the size of its firms.

Then it is important for many people that they should secure a house appointment upon qualification. If one selects a hospital which has relatively few such appointments but a large number of students, then manifestly is lessened one's chance of getting such a job. It may influence a man if he is scientifically inclined in choosing between a hospital with a grand tradition and one which has a reputation for achievements in research. It can readily be realized, however, that a hospital which excels in one respect is apt to fall short in another, and only by balancing the pros and cons can one arrive at a satisfactory conclusion. And it is plain to anybody who has been over and investigated the facts concerning a number of teaching hospitals that there is very little indeed to choose between them. Some of them look execrable, a few nearly superb; but none of them has been condemned by a Royal Commission; patients still patronize them and likewise swear by them; students through the same exams. The principle of medicine behind them all is identical; it is a matter of distinguishing between members of the same species.

If one had no prejudices, was insensitive to environment, and acted on "hit or miss" principles, then one might make one's selection with the aid of a pin. But if one preferred to assert one's free will, did not feel obliged to follow the herd, or was not bound by familial usage, then one would have to discriminate between subtle points and take into consideration factors which

might be deemed trivial were they not so hard of analysis. In this way features such as the site of the hospital, type of one's fellow students, become important. If one does not want to share the medical school with amateur chemists, physicists, biologists, and so on, then one will choose a hospital which covers only the clinical part of the curriculum.

Essential Features of a Teaching Hospital

- (a) Size.
 - Number of beds.
 - Number of students.
 - Dimensions of firms.
 - (Proportions of beds, honoraries, and students should be such that firms are not unwieldy or short of material.)
- (b) Modernity:
 - Buildings.
 - Apparatus.
- (c) General Outlook of Place:
 - Scientific or traditional?
- (d) Staff:
 - Number of honoraries and others.
 - Status.
- (e) House Appointments:
 - Opportunity of obtaining them.
 - Standing relative to those of other hospitals.
- (f) Research:
 - Extent to which furthered.
 - Particular line.
 - Merit.
 - Funds.
- (g) Status of Hospital as a whole.
- (h) Situation of Hospital:
 - Central or otherwise.
 - Availability of neighbouring lodgings.
 - Hostel.
- (i) Scholarships, etc.
- (j) Extent of Studies:
 - Whether entire medical syllabus covered or only the clinical portion.
- (k) Arrangement of Courses.

THE CURRICULUM TO-DAY

In 1922 the General Medical Council prescribed a readjustment of the medical curriculum, to come into force in the following year. The scheme adopted was in effect a compromise between several "schools of thought" which had been debating the matter for fifteen years or more. In this readjustment, among other things, increased emphasis was placed upon sufficient opportunity being afforded for the study, both theoretical and clinical, of subjects such as ophthalmology, venereal disease, orthopaedics, ante-natal conditions, and infant welfare, and upon the importance of preventive aspects of medicine. We summarize below the leading features of the revised scheme of professional study and examination which has applied since the beginning of 1923. The first qualifying examinations based upon this readjusted curriculum were held in 1928.

The minimum age for registration as a medical student is now 17 years. There has been no formal lengthening of the medical curriculum under the revised scheme, but in practice it has been added to by transferring to preliminary study and examination the subjects of elementary physics and chemistry in their purely scientific aspects. Thus, in addition to passing a preliminary examination in general education, an examination (written, oral, and practical) in the elements of physics and chemistry is required by the General Medical Council before the admission of a name to the *Students Register*. In the applications of these two subjects to the professional courses—as in biophysics, biochemistry, and pharmacological chemistry—appropriate instruction is supposed to

continue throughout the curriculum, and to be tested by examination. If he has had no facilities at school or otherwise for obtaining what is necessary for the preliminary or pre-registration examination in chemistry and physics, then he can come for it to the university or medical school, but study for this will not count as part of the curriculum. The examination in elementary biology is not "pre-curriculum," but the instruction may be so, and a licensing body can allow students who so desire to sit for the examination immediately after matriculation. Here again, however, it is the wish of the Council that the applications of biology to medicine, surgery, and midwifery shall continue to receive adequate attention throughout the courses.

The General Medical Council

The General Medical Council was established by the Medical Act, 1858, in order "that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners." Eighteen members of the Council are appointed by the Universities in the United Kingdom having medical faculties; nine by the Medical Corporations, such as the Royal Colleges of Physicians and Surgeons; five by His Majesty in Council; and seven members are directly elected by members of the profession as a whole—a total of thirty-nine. To these are added three dentists who are members of the Dental Board, and are appointed for dental business. Although the eighteen members appointed by the Universities and the five members appointed by His Majesty in Council may all be laymen, only two laymen have so far been appointed; the first of these was appointed by the Privy Council in 1926, and, on his resignation in 1931, another was appointed in his place. Both were members of His Majesty's Privy Council.

The Council's offices are at 44, Hallam Street, Portland Place, London, W.1, and there are Branch Offices at 12, Queen Street, Edinburgh 2, and 35, Dawson Street, Dublin.

The Council exists for the protection of the public and not of the profession. Its principal functions are three. First, to keep the *Medical Register*; second, to see that the name of no person is entered thereon as qualified unless he has had an adequate professional education, and to remove therefrom the names of qualified persons who are no longer entitled to public confidence; and third, to provide for the publication of the *British Pharmacopoeia*. It is the appearance of a name upon the *Medical Register*, and not the possession of a degree or diploma, that constitutes a person a "duly qualified" or "legally qualified" practitioner of medicine.

The Council has no power to make rules in regard to the medical curriculum or examinations, but it can pass resolutions and make recommendations relating thereto, and, if any of these were ignored by the licensing bodies, it would be open to the Council to make representations to the Privy Council, which if it thought fit, might order that the qualifications obtained from such bodies should not be registrable.

The name of any medical practitioner who has been convicted of felony or misdemeanour, or who is judged, after due inquiry before the Council itself to have been guilty of "infamous conduct in any professional respect," may be erased from the *Medical Register*.

The Medical Acts prohibit attempts being made to impose restriction as to any theory of medicine or surgery, and, once a practitioner has been trained and tested in the knowledge essential for public safety, he may adopt any "theory" of medicine or surgery in which he honestly believes. The Medical Acts do not prohibit the practice of medicine by unregistered persons, but if they "wilfully

and falsely "assume any title implying registration they are liable to prosecution. In this respect the Medical Acts differ from the Midwives and the Dentists Acts, which entirely preclude the practice of midwifery or dentistry by unregistered persons. Unregistered medical practitioners, however, are under certain disabilities, for they cannot recover charges for medical or surgical attendance, etc., in a court of law; they cannot hold an appointment as medical officer of health, in public (including mental) hospitals, or as a medical officer in the Military or Naval Services, or in ships; they cannot give any valid certificate which is required by any Act from a medical practitioner—for example, a certificate of death; and they cannot engage in insurance practice, obtain dangerous drugs, or attend cases of venereal disease.

An account of the recommendations which the Council has drawn up in respect of the education of medical students here follows.

Registration of Medical Students

The Council recommends that every intending student of medicine should be registered as such at one of its three offices, whose addresses are given on page 393.

Candidates must produce evidence (a) that they have attained the age of 17 years; (b) that they have passed an examination in general education which is accepted for matriculation or entrance to the Faculties of Arts or Pure Science in a university in the United Kingdom; and that in addition thereto they have passed an examination in elementary chemistry and elementary physics conducted or recognized by one of the licensing bodies.

Application for registration should be addressed to the Registrar for the Division of the United Kingdom in which the applicant is residing—England and Wales, or Scotland, or Ireland. It must be made on a special form, which can be obtained from any of the offices of the General Medical Council itself, or from one of the various licensing bodies or medical schools.

The regulations with regard to registration apply alike to medical and to dental students, with the exception that for dental students pupillage with a registered dental practitioner may be regarded as the beginning of professional study, and that applications for registration should be addressed to the London office of the Council only.

Professional Education

The rule is that it is only from the date which appears against his name in the *Students Register* that the medical student's career officially begins; thereafter five academic years at least must pass before he can present himself for the final examination for any diploma entitling its lawful possessor to registration as a qualified medical practitioner under the Medical Acts. But to meet the circumstances brought about by the dates at which sessions of the medical schools begin and end, the close of the fifth year may be reckoned as occurring at the expiration of fifty-seven months from the date of registration. In any case, the period of five years must be one of bona-fide study; and in every course the following subjects should be included:

- (i) Elements of General Biology, including an introduction to *Microbiology*. This course, if the licensing bodies permit, may be taken before registration, and the examination may be deferred.
- (ii) Chemistry, Physics, and Biology in their application to Medicine.
- (iii) Human Anatomy and Physiology, including Histology, Elements of Embryology, Biochemistry, and Biophysics.
- (iv) Elementary Bacteriology, before regular clinical appointments.
- (v) Pathology, general, special, and clinical, and Morbid Anatomy.
- (vi) Pharmacology and Materia Medica, to be taken concurrently with clinical instruction.
- (vii) Forensic Medicine, Hygiene, and Public Health.

(viii) Medicine, including Applied Anatomy and Physiology, Clinical Pathology and Therapeutics, Children's Diseases, Acute Infectious Diseases, Tuberculosis, Mental Diseases, Skin Diseases, and Vaccination.

(ix) Surgery, including Applied Anatomy and Physiology and Clinical Pathology, Anaesthetics, Diseases of the Eye, Ear, Throat, and Nose, Radiology, Venereal Diseases, and Orthopaedics.

(x) Midwifery and Diseases of Women, including ante-natal conditions and infant hygiene.

The Council recommends that during the last three of the five academic years clinical subjects shall be studied.

The first two years must be passed at a university, or at a school of medicine recognized by any of the licensing bodies, and the remainder must be devoted to clinical work at any public hospital or dispensary at home or abroad which is recognized by a licensing body.

Special Considerations

The requirements of the General Medical Council in respect of the education of those who desire to enter the medical profession have now been given in outline, but before leaving this part of the subject the steps which the aspirant should take may be rehearsed in their due order:

- (1) Pass an examination in arts;
- (2) Pass an examination conducted or recognized by a licensing body in elementary physics and elementary chemistry;
- (3) Having attained the age of 17, enter himself at a university or at a medical school recognized by one of the licensing bodies;
- (4) Obtain registration as a medical student;
- (5) Study for a minimum of five years certain prescribed subjects;
- (6) Meanwhile pass sundry intermediate examinations; and at the end of the fifth year pass a "qualifying examination" which will entitle him to receive from a licensing body a qualification enabling him to obtain registration in the *Medical Register*, whereby he receives legal authority to practise.

The Minimum Period.—It must be remembered that the period of five years is a minimum; more is often required, even by the man of good abilities and reasonable industry, and some of the universities prescribe a longer period. Besides these qualities a student, to obtain a registrable qualification in the minimum period of five years, or fifty-seven months, must have a considerable amount of good luck; in other words, he must keep in good health through every term, and never fail at a single examination. Thus, for instance, before presenting himself for any examination he must be "signed up" for the subjects covered by that examination; this means that his teachers have to certify that he has diligently attended the required number of lectures or classes in the subjects in question. If, however, the student happens to be ill during the term when such lectures or classes are taking place, he may miss enough of them to make it impossible for him to be signed up. Then again, should he fail to satisfy the examiners at some examination, he cannot present himself for re-examination for at least three months. This generally entails further consequences, because, apart from the student's success at the next stage in his career being imperilled by the need for restudying the subjects in which he has failed, the Examining Boards usually insist upon a definite interval elapsing between one examination and the next. Further, many Boards have refused to recognize lectures and classes which have been attended before the student has passed the requisite examination in earlier subjects, and the Council now recommends that the professional examinations in anatomy and physiology be passed before the minimum period of three years' subsequent study be entered on; in other words, no clinical study should count as such until these examinations have been successfully completed. Failure at an examination may thus not only mean deferment of the date of examinations, but deferment of the beginning of the student's study of certain subjects. It is thus exceedingly easy for a student

to fail to qualify in five years, and, as a fact, the majority of students take longer.

In speaking of the minimum period, it is to be remembered also that that time is only sufficient to gain a registrable qualification, such as a Bachelorship of Medicine or Surgery or the diplomas of the Royal Colleges. Those who wish to take a higher qualification—for instance, the F.R.C.S. Eng.—must prolong their work for another year or more. So, too, in some cases, must those who desire to convert their Bachelorship into a Doctorate. This may entail further formal examination, but at some universities the M.D. is obtainable on presentation of a thesis when the Bachelor has attained a certain age and has practised for a certain number of years. However, a student's career proper may be considered, perhaps, to have ended when he obtains his first registrable qualification, for while preparing himself for any further tests he can, and usually does, hold some junior appointment which more or less covers his expenses.

Memorandum on Students' Registration

The following memorandum has been drawn up on behalf of the General Medical Council as to the procedure for those who desire to be registered as medical or dental students.

The requirements for the registration of medical and dental students are the same, and every intending student should, in his own interest, register as soon as he begins his professional curriculum.

A recognized examination in general education must first be passed. If the student intends to obtain a university degree, he should apply to the university he selects for information as to its matriculation requirements in arts or pure science, or as to any examinations which may be accepted in fulfilment thereof. If the student intends to obtain a qualification from one of the licensing corporations (these are the Conjoint Boards in England, Scotland, and Ireland, the Society of Apothecaries of London, and the Apothecaries' Hall of Dublin), any of the examinations indicated below will be accepted. The subjects required are: (1) English, (2) Mathematics (elementary), (3) a language other than English, and (4) a fourth subject as required by the regulations of the particular examination, to be chosen from the following—namely, History, Geography, Botany, Physical Science, Natural Science, Latin, Greek, Hebrew, French, German, or other language accepted by a university for matriculation. School certificates (other than "Higher") must show "Credits" in each of the prescribed subjects. When school certificates with four credits are presented, or certificates from the Educational Institute of Scotland and College of Preceptors, the passes in the four subjects must be shown to have been obtained at not more than two sittings.

The requirements of the preliminary examination in general education being satisfied, it is then necessary for the student to pass a further or pre-registration examination (theoretical and practical) in elementary chemistry and elementary physics, which is conducted by the Corporation of the licensing bodies—that is, a Corporation. These subjects must be passed included in the preliminary examination—for example, chemistry taken as one of the four required subjects in the preliminary examination cannot also count as one of the subjects of the pre-registration examination. These subjects may be studied at a university or medical school, or at a secondary school or other institution recognized by the body whose pre-registration examination it is intended to take. The student should, in every case, write beforehand to the body whose qualification he desires to obtain (a list will be found below) for information in regard to its requirements for this examination, and, although it is not necessary to pass in biology before registration as a student, application should be made at the same time to the body selected to ascertain their requirements in regard to this subject.

These two examinations (in general education and in physics and chemistry) having been passed, and the student having attained the age of 17 years, he should apply to one of the universities or one of the medical schools for admission to its course of medical study. When medical study has been begun, he should apply to the Dean of the School, or to the Registrar of one of the branches of the General Medical Council, for a form of application for registration as a student, and should have it completed and sent in to one of the Branch Councils as soon as possible. There is no fee for this registration. The medical curriculum will extend for at least

five years, and the dental curriculum for at least four years, from the date of registration as a student.

A dental student may begin his curriculum, if he so desires, as a pupil in dental mechanics of a registered dental practitioner; but study at a dental school is to be preferred. If, however, he is apprenticed to a dental practitioner, he will have to devote twice as much time to instruction in dental mechanics as he would if he had taken this subject in a school. This will have the effect of lengthening the curriculum. In any case a student can only obtain a concession of twelve months out of the four years' curriculum in respect of such apprenticeship.

The addresses of the Branch Registrars are:

General Medical Council, 44, Hallam Street, Portland Place, London, W.1.

Scottish Branch Council, 12, Queen Street, Edinburgh, 2.

Irish Branch Council, 35, Dawson Street, Dublin.

Examining Bodies in Preliminary Education

The following is a list of the officials of the examining bodies in preliminary education, with the names of the examinations in parentheses.

Secretary, Queen's University of Belfast. (Matriculation.) Assistant Secretary, Ministry of Education. (Senior Certificate.) Registrar, The University, Bristol. (Matriculation, School Certificate, or Higher School Certificate.)

Registrar, The University, Cambridge. (Previous.) Secretary, Cambridge Local Examinations, Syndicate Buildings, Cambridge. (School or Higher School Certificate.)

Medical Registrar, University of Dublin (Trinity College), Dublin. (Entrance examination to the School of Physics.)

Registrar, University of Durham College of Medicine, Newcastle-upon-Tyne. (Matriculation, School or Higher School Certificate.)

Registrar, Irish Conjoint Board, Royal College of Surgeons, Dublin. (Preliminary Examination.)

Registrar, National University of Ireland, Dublin. (Matriculation.)

The Assistant Commissioner of the Department of Education, 1, Hume Street, Dublin. (Senior Grade Examination or Leaving Certificate.)

Assistant Secretary, Ministry of Education, Belfast. (Senior Grade or Leaving Certificate.)

Secretary of the Examinations Council, The University of London, South Kensington, London, S.W.7. (Matriculation, General, or Higher School Certificate.)

Secretary, Northern Universities Joint Matriculation Board, 315, Oxford Road, Manchester. (Matriculation, School, or Higher School Certificate.)

Registrar, University Registry, Oxford. (Responsions.)

Secretary, Oxford and Cambridge Schools Examination Board, Schools Examination Office, Balliol College, Oxford. (School or Higher School Certificate.)

Secretary, Oxford Local Examinations, University Press, Oxford. (School or Higher School Certificate.)

Secretary, College of Preceptors, Bloomsbury Square, London, W.C.1. (Senior Certificate at Credit Standard.)

Secretary, Educational Institute of Scotland, 47, Moray Place, Edinburgh. (Preliminary Medical Certificate.)

Secretary, Scottish Education Department, 14, Queen Street, Edinburgh. (Leaving Certificate.)

Secretary, Scottish Universities Entrance Board, St. North Street, St. Andrews. (Scottish Universities Preliminary Examination.)

Registrar, University of Wales, Cathays Park, Cardiff. (Matriculation.)

Clerk, Central Welsh Board, Cardiff. (School or Higher School Certificate.)

[Note.—Certificates of the College of Preceptors and School Certificates (other than "Higher") must show "Credits" in each of the prescribed subjects.]

Licensing Bodies

The following is a list of the officials of licensing bodies and their addresses:

ABERDEEN, The Secretary of the Medical Faculty, The University.

BELFAST, The Secretary, Queen's University.

BIRMINGHAM, The Registrar, The University.

BRISTOL, The Registrar, The University.

CAMBRIDGE, The Registrar, The University.

DUBLIN, The Medical Registrar, The University, Trinity College.

The Registrar, National University of Ireland.

DURHAM, The Registrar, University of Durham College of Medicine, Newcastle-upon-Tyne.

EDINBURGH, The Dean of the Faculty of Medicine, The University.

GLASGOW, The Registrar, The University, W.2.

LEEDS, The Registrar, The University.

LIVERPOOL, The Registrar, The University.

LONDON, The Academic Registrar, The University, South Kensington, S.W.7.

MANCHESTER, The Registrar, Victoria University.

OXFORD, The Dean, Department of Medicine, The University.

ST. ANDREWS, The Secretary, The University.

SHEFFIELD, The Registrar, The University.

WALES, The Registrar, The University Registry, Cathays Park, Cardiff.

Licensing Corporations

ENGLISH CONJOINT BOARD, The Secretary, 8, Queen Square, Bloomsbury, W.C.1.

SCOTTISH CONJOINT BOARD, The Secretary, 49, George Square, Edinburgh.
 IRISH CONJOINT BOARD, The Secretary, Royal College of Surgeons in Ireland, Dublin.
 APOTHECARIES' SOCIETY OF LONDON, The Secretary of the Court of Examiners, Blackfriars, London, E.C.4.
 APOTHECARIES' HALL OF IRELAND, The Registrar, 95, Merrion Square, Dublin.

The following is a list of medical schools (other than universities) and their officials.

ABERYSTWYTH, The Registrar, University College. (University of Wales. First year only.)
 BANGOR, The Registrar, University College. (University of Wales. First year only.)
 CARDIFF, The Dean of the Medical School, Welsh National School of Medicine.
 The Registrar, University College of South Wales and Monmouthshire.
 CORK, The Registrar, University College.
 DURHAM, The Registrar, College of Medicine, Newcastle-upon-Tyne.
 DUBLIN, The Medical Registrar, University of Dublin, Trinity College.
 The Registrar, University College.
 EDINBURGH, The Dean, School of Medicine, Royal College of Surgeons, Surgeons' Hall.
 GALWAY, The Registrar, University College.
 GLASGOW, The Dean, St. Mungo's College.
 The Dean, The Anderson College of Medicine.
 The Mistress, Queen Margaret College, W.2 (for women students of the University of Glasgow).
 LONDON, Charing Cross Hospital, The Dean of the Medical School, W.C.2.
 Guy's Hospital, The Dean of the Medical School, S.E.1.
 King's College, The Dean of the Medical Science Faculty, Strand, W.C.2.
 King's College Hospital, The Dean of the Medical School, S.E.5.
 London Hospital, The Dean of the Medical College, W.2.
 London (Royal Free Hospital) School of Medicine for Women, The Dean, 8, Hunter Street, W.C.1.
 Middlesex Hospital, The Dean of the Medical School, W.1.
 St. Bartholomew's Hospital, The Dean of the Medical College, E.C.1.
 St. George's Hospital, The Dean of the Medical School, S.W.1.
 St. Mary's Hospital, The Dean of the Medical School, S.E.1.
 St. Thomas's Hospital, The Dean of the Medical School, S.E.1.
 University College Hospital, The Dean of the Medical School, W.C.1.
 Westminster Hospital, The Dean of the Medical School, S.W.1.
 SWANSEA, The Registrar, University College. (University of Wales. First year only.)

This section of the Educational Number would be incomplete without brief mention of the memorandum drawn up on behalf of the General Medical Council on the procedure to be adopted by those who desire to enter the profession of medicine, to which reference is made in the introductory article at page 386. The pamphlet (price 1s. post free) sets out in plain language the information for which the Council is often asked by prospective medical students or their guardians.

Universities in England and Wales

There are eleven universities in England and Wales, and some account of each of them follows. They all have now fully developed medical faculties.

UNIVERSITY OF OXFORD

The professional degrees conferred by this university are those of Bachelor of Medicine (B.M.) and Bachelor of Surgery (B.Ch.) (taken together), Doctor of Medicine (D.M.), and Master of Surgery (M.Ch.). It also grants a diploma in ophthalmology. On receiving the B.M., B.Ch. the candidate is entitled to registration by the General Medical Council. In favourable circumstances these degrees may be obtained in six or seven years from matriculation. Before receiving either, the candidate must have taken a degree in arts (B.A.), for which three years' residence within the university is necessary. This, however, does not necessarily mean deferment of the professional study for that period, for the subjects chosen for those in which examinations would in any case have to be passed for the medical degree, and the courses are dovetailed together.

Women members of the university are admitted to medical degrees under the same conditions as those laid down for men in regard to examinations, courses of study, and fees, and under corresponding conditions as to residence at the university. Among the university diplomas open to women are those in anthropology and ophthalmology.

There are numerous avenues to the B.A. degree, but that which constitutes the 'normal' course for medical students, as being the most closely related to their medical studies, is the following: By passing Responsions (or one of the examinations which are accepted as equivalent), some of the preliminary examinations in the Natural Science School, in the first public examination; and one of the final honour examinations in the Final Honour School of Natural Science—physiology being that usually taken.

Responsions and the preliminary examinations in natural science may, provided the candidate's name is entered through a College, be passed before a candidate is a member of the university; a Final Honour School may be taken at the end of the third or fourth academical year—that is, within nine or twelve terms respectively; the preliminary examinations of the Natural Science School may be taken as soon as Responsions has been passed or exemption obtained.

Professional Degrees

To obtain the B.M., B.Ch. degrees the candidate must first pass in four of the subjects of the preliminary examination of the Natural Science School—namely, physics, chemistry, zoology, and botany.

He then has two further examinations to pass—the First B.M. and the Second B.M. These take place twice a year, in June and in December. Every candidate at the first B.M. is examined in human anatomy, in physiology, and in organic chemistry, but is excused from the Honour School of Physiology, and from organic chemistry if he has obtained a first or second class in the Honour School of Physiology. Once he has passed this examination he can, on production of certain certificates, be examined as soon as he pleases in pathology, forensic medicine and hygiene, materia medica, and pharmacology (subjects of the Second Examination), but cannot present himself for the remaining subjects—medicine, surgery, and midwifery—until the eighteenth term from the day of his matriculation unless he be already a registered medical practitioner, and not until a period of at least thirty-three months has elapsed from the date of his passing the First Examination, and he must pass in all these three subjects at one and the same time.

Before admission to the Second B.M. examination the student must produce certificates of instruction from a medical school recognized by the university, of having acted as clinical clerk and dresser, each for six months, and as post-mortem clerk for three months, of having on labours, of instruction in infectious and mental diseases and ophthalmology, etc., and of proficiency in vaccination and the administration of anaesthetics, and of three academic years of hospital attendance. He must also produce certificates of attendance in laboratory courses in pathology, bacteriology, and pharmacology, either in Oxford or in a recognized medical school.

D.M. and M.Ch. Degrees

A Bachelor of Medicine who wishes to proceed to the D.M. must have entered his thirtieth term and must present, for approval by the appointed examiners, a dissertation on a subject previously approved by the Regius Professor of Medicine. If a candidate for the M.Ch. he

¹ The four subjects of the medical preliminary examinations are four of the subjects in the natural science preliminary, and can be commenced directly after passing Responsions.
² Membership is constituted by Matriculation and by becoming a member of a College or a Hall or of St. Catherine's Society or of the Society of Oxford Home-Students.
³ For details of the required certificates see *Examination Statutes*, Clarendon Press, Oxford, latest edition.

must have entered his twenty-first term and must pass an examination, which is held in June.

The examination for the diploma in ophthalmology is held annually in June.

Teaching

The several colleges provide their undergraduate members with tutors for all examinations up to the B.A. degree. In addition, the university provides certain courses of instruction, including lectures, demonstrations, and practical work, which cover all the subjects of the Preliminary Examination and First B.M., and to some extent those of the Final Examination.

Scholarships

Entrance Scholarships (of the maximum value of £100 p.a.) and Exhibitions (usually of a maximum value of £50) are awarded by various Colleges after competitive examination in Natural Science subjects, and are open to intending students of Medicine equally with other Natural Science candidates. These are usually tenable for four years and restricted to candidates under 19 years of age. Particulars can be obtained on application to the College tutors. At two Colleges (University and Pembroke) there are entrance scholarships restricted to intending students of medicine. Scholarships for women are also offered by various women's colleges, from the principals of which details of the examinations may be obtained. A Radcliffe Travelling Fellowship of £300 a year, tenable for two years, is conferred annually; candidates must have taken the B.M. degree. A Schorstein Research Fellowship of £200 a year for two years is awarded biennially. The Fellow must engage in research in one of the medical departments of the university. A George Herbert Hunt Travelling Scholarship of about £100 is awarded biennially to enable a young medical graduate to spend three months abroad in medical study. A Philip Walker studentship in Pathology of £200 a year, tenable for two years, is awarded biennially for the encouragement of research in pathology, as also are the Rolleston Memorial Prize and the Radcliffe Prize (£50), for research in natural science (including pathology), and the three Theodore Williams Scholarships in Anatomy, Physiology, and Pathology, of the value of £50 each, tenable for two years. A Radcliffe Scholarship in Pharmacology of £50 for one year, open to the university, is awarded annually by the Master and Fellows of University College.

FEES

An annual fee of £4 10s. is paid to the university for the first four years, being reduced to £1 when the B.A. has been taken. For the degrees the fees are: the B.A., £7 10s.; the B.M. and B.Ch., £14; the D.M., £20; the M.Ch., £12. College fees, varying in amount, are paid for the first four years of membership and in taking degrees. Tuition fees vary from £21 to £30. The minimum annual cost of living during the three university terms may be regarded as not less than £200, or for women not less than £140.

For further information application may be made to Dr. K. J. Franklin, Dean of the Medical School, University of Oxford.

UNIVERSITY OF CAMBRIDGE

The professional degrees given by this university are those of Bachelor of Medicine (M.B.) and Bachelor of Surgery (B.Chir.), each of which entitles the possessor to admission to the Register by the General Medical Council, and the higher degrees of Doctor of Medicine and Master of Surgery. It also grants a diploma in medical radiology and electrology to medical practitioners, not necessarily graduates of the university. Information regarding this diploma will be found in a later section under the heading "Radiology." A candidate for the M.B., B.Chir. degrees need not possess a degree in arts; it is sufficient if he has passed the Previous Examination or some other examination accepted by the university as its equivalent. Most students, however, are advised to take the B.A. degree, preferably by obtaining honours in the Natural Sciences Tripos. The attainment of a sufficient standard in certain subjects in this Tripos will secure exemption from the corresponding tests in the M.B. course. Members of Girton College and Newnham College are admitted to the examinations.

Professional Examinations

An explanation of the changes in the medical curriculum at Cambridge, which come into force in October, 1934, will be found in a leading article published in the *British Medical Journal* of July 7th, 1934 (p. 26).

To obtain the M.B. degree the candidate must pass the First and the Final M.B. Examinations and keep an Act. The B.Chir. degree (which is a registrable qualification) may be obtained after passing the Final Examination without keeping an Act.

First M.B.—This comprises (1) general and inorganic chemistry, (2) physics, (3) elementary biology, (4) organic chemistry. The parts may be taken together or separately. In either case the candidate, before admission to examination, must have passed or been exempted from the previous examination. Certain exemptions from the First M.B. Examination are allowed; the regulations may be obtained from the Registry. An examination in each part is held three times in the year.

A candidate for the Final Examination must have (a) completed the First Examination; (b) dissected the whole body adequately and thoroughly; (c) attended an approved course, and passed an examination in Pharmacology; (d) attained the honours standard in some Tripos; (e) attended an approved course, and passed an examination in anatomy and (f) in physiology.

Final M.B.—This is divided into two parts, to neither of which the candidate is admitted until he has fulfilled the conditions previously mentioned. A candidate for the first part, which deals with the principles and practice of surgery (including special pathology) and midwifery and diseases peculiar to women, must have completed five years of medical study and be signed up in these subjects, and have completed two years and a half of hospital practice. Before admission to the second part the candidate must have completed five years of medical study, and be duly signed up in all subjects and have completed three years of hospital practice. The examination is in the principles and practice of physic (including diseases of children, mental diseases, and medical jurisprudence), pathology (including hygiene and preventive medicine), and pharmacology (including therapeutics and toxicology). The Final M.B. examinations are held twice a year—in June and December.

Act for the M.B.—Before receiving his M.B. degree a candidate who has passed the Final M.B. examinations has to write a thesis. This he reads in public on an assigned day, and is then questioned concerning it and other subjects of medicine by the Regius Professor of Physic. If approved at this test he is then certified as having "kept the Act," and in due course receives his degree. Medical degrees may be taken in absence by those living abroad, the candidate sending to the Registry a dissertation, which is laid before the Degree Committee.

The Higher Degrees

The M.D. degree may be taken by a graduate of the University of eight years' standing who has passed the Final M.B. Examination, after writing a thesis approved by the M.D. Degree Committee, and keeping a further Act. He may also be allowed or required to take an examination, oral or written, or both, on the field of Medicine within which the subject of his thesis falls.

A candidate for the M.Chir. degree who is an M.A. may be admitted to the examination after he has become legally qualified to practise surgery. Other candidates may be admitted when two years have elapsed after they have completed the requirements for the B.Chir. degree, and may be admitted to the M.Chir. degree after three years have elapsed since they were admitted to the B.Chir. degree. The examination comprises pathology, surgery, surgical anatomy, and surgical operations. The tests are partly in writing, partly oral, and partly practical: they include the writing of an extempore essay. The examination is held in February in each year.

In addition to college fees, tutorial fees, and the expense of living, the following examination fees are payable: First M.B., £5 5s.; tests in Pharmacology, Physiology, and Anatomy, £1 1s.; Final M.B., £12 12s. For schedules referring to the examinations, lists of schools and hospitals recognized by the university, and other information, application should be made to the University Registry, Cambridge.

FEES

UNIVERSITY OF LONDON

Under the regulations of the University of London the degrees obtainable in the Faculty of Medicine are those of Bachelor of Medicine and Bachelor of Surgery, Master of Surgery in four branches, Doctor of Medicine in six different branches, Bachelor of Dental Surgery, and Bachelor of Pharmacy. The university has its own matriculation examination, and it is most advisable that candidates should obtain and carefully study the booklets relating to it. The matriculation examination is open to any person, of either sex, who has attained the age of 16. It is held in January, June, and September, and lasts four days; the first two take place both in London and in certain provincial centres; the September examination is held in London only.

In no circumstances is a degree granted to anyone in less than three years after the date at which he passed the matriculation examination or obtained registration in some other way. All medical students must normally spend not less than five and a half years in professional study subsequent to matriculation, of which the last three years must be spent at a school of advanced medical studies.

Professional Examinations

M.B., B.S.—There are three examinations, the last two being subdivided. They are held twice a year.

The First Examination (held in July and December) covers inorganic chemistry, general biology, and physics, there being two papers, a practical test, and a possible oral test in each subject. The names of successful candidates are placed in alphabetical order, with a note as to any subject in which a candidate has distinguished himself or herself.

The Second Examination is held in March and July. Part I covers organic chemistry, the candidate's knowledge being tested as in the earlier examination. Candidates for Part II must have passed the First Examination at least eighteen months previously, besides having completed Part I of the Second Examination. The subjects are anatomy, physiology, and pharmacology, the tests being written, oral, and practical. Candidates who fail in pharmacology may sit for re-examination in that subject alone if the examiners think fit, and candidates who pass in pharmacology only may similarly be credited with that subject.

No candidate, unless he is already a registered medical practitioner, is admitted to the Third M.B., B.S. Examination within three academic years from the date of his completing the Second Examination. The subjects are medicine (including mental diseases), pathology, forensic medicine and hygiene, surgery, and obstetrics and gynaecology. They may be divided into two groups, one comprising medicine, pathology, forensic medicine, and hygiene, and the other surgery and obstetrics and gynaecology. Either group may be taken first at the option of the candidate, or the groups may be taken together. Only candidates who show a competent knowledge of all the subjects comprising a group are passed. There is no separate examination held for honours, but the names of successful candidates, who have passed both groups of the examination at one time, are divided into an honours list and a pass list, and a university medal may be awarded the candidate who has most distinguished himself in the whole examination. A supplementary list is issued of candidates who have passed in one group only.

The Higher Degrees

M.D.—An examination for the M.D. is held twice yearly—in December and July. Every candidate must have passed the examination for the M.B., B.S., unless he became M.B. before May, 1904. He may present himself for examination in any one of the following branches: (1) medicine, (2) pathology, (3) mental diseases and psychology, (4) midwifery and diseases of women, (5) hygiene, (6) tropical medicine, and, if he wishes, may pass also in another branch at a subsequent examination.

Two years must elapse between acquiring the M.B., B.S., and sitting for the M.D. in any branch, except that in the case of Branches I-IV a candidate who has obtained honours at the M.B., B.S. Examination may enter for the M.D. Examination after one year. Candidates may also be admitted to the M.D. Examination (Branches I-VI) one year after taking the M.B., B.S. Examination on the grounds of exceptional experience in their subject. Certificates of approved appointments are required for the M.D. (Branches I-IV), except in the case of candidates who have been engaged in professional practice for five years. In each branch the scheme of examination is the same: two papers on its special subject, a paper on an allied subject—for example, an essay on one of two suggested topics connected with the special subject, and a clinical or other practical test. Both written and practical examinations must be passed, though exemption can be obtained from the former in exceptional circumstances. In any branch of the M.D. Examination a gold medal of the value of £20 may be awarded.

M.S.—The regulations with regard to the Mastership in Surgery are of a corresponding kind, but there are four branches in which it may be obtained—general surgery, dental surgery, ophthalmology, and laryngology, otology, and rhinology.

FEES

For Matriculation: 2½ guineas for each entry. First Examination: 6 guineas for each entry to the whole examination. For re-examination in one subject the fee is 2 guineas. Second Examination, Part I: 3 guineas for the first and each subsequent entry. Second Examination, Part II: 9 guineas for each entry to the whole examination. For re-examination in Pharmacology the fee is 4 guineas. For re-examination in Anatomy and Physiology the fee is 6 guineas. M.B., B.S. Examination: 12 guineas for each entry to the whole examination, and 6 guineas for each entry to the whole in either group. M.D. and M.S. Examinations: 20 guineas, and 10 guineas on re-examination. Inquiries should be addressed to the Academic Registrar, the University of London, South Kensington, S.W.7.

UNIVERSITY OF BIRMINGHAM

This university confers medical and surgical degrees—namely, M.B., Ch.B., M.D., Ch.M., and M.D. (State Medicine)—and also diplomas and degrees in State medicine and dentistry. The M.B., Ch.B. candidate may also combine with the earlier part of his medical curriculum courses leading to the ordinary B.Sc. degree in anatomy and physiology. The degree of B.Sc. with honours in one of these subjects requires an extra year. The full course of study for the degrees of M.B., Ch.B. extends over six years. The Senate has power to accept courses of study and examinations passed at other recognized universities as exempting from the examinations in physics, chemistry, biology, and organic chemistry. In the case of such students at least three years must be spent in attendance upon classes at the university. A degree of Ph.D. is also conferred for research study in medicine under special regulations. Candidates must be graduates in medicine of a recognized university. Students entering the Medical Faculty for the M.B., Ch.B. degrees must have passed—

(1) Either (a) the matriculation examination of the Joint Board of the Universities of Manchester, Liverpool, Leeds, Sheffield, and Birmingham; or (b) some other examination recognized as equivalent to the matriculation. Candidates

for medical degrees are required to have passed in English literature and mathematics, and are recommended to take Latin and a science subject—chemistry or physics—at the matriculation examination. The matriculation examination of the Joint Board is held in July and September. The regulations and the list of examinations accepted in lieu thereof will be sent on application to the Secretary to the Board, Joint Matriculation Board, 315, Oxford Road, Manchester.

(2) A recognized pre-registration examination in the subjects of chemistry, physics, and biology—for example, the higher school certificate of the Joint Matriculation Board; or a candidate may attend first-year courses in the university, October to June (chemistry, physics, and biology)—that is, First M.B., Ch.B. This examination may be passed in two sections; not less than two subjects must be passed on first entry.

Professional Examinations

The candidate for the M.B., Ch.B. degrees has five examinations to pass, subsequent to passing the First M.B., Ch.B. Examination or exemption therefrom. In the Second (Part II) and Final examinations the candidate must pass in all the prescribed subjects or undergo the whole examination again.

The First M.B. deals with physics, chemistry, and biology (pre-registration). The Second M.B. (Part I) comprises the subject of organic chemistry. The Second M.B. (Part II) comprises anatomy and physiology, and the student must pass in both simultaneously. The Third M.B. comprises pathology and bacteriology taken as one complete subject. The fourth M.B. takes place at the end of the fifth year, the subjects being forensic medicine, toxicology, public health, and therapeutics (inclusive of pharmacology and materia medica).

Final M.B.—This comprises medicine, surgery, midwifery and diseases of women; ophthalmology, and mental diseases. The candidate, in addition to more ordinary certificates, must be prepared with a certificate of having acted as a post-mortem clerk for three months, and received special instruction in anaesthetics and clinical instruction in diseases peculiar to women, asylum ward work, ophthalmology, children's diseases, venereal diseases, ear and throat and skin diseases, etc. In respect to ophthalmology he must show that he has learnt refraction work. He also has to present to the examiners at the time of his examination a short written commentary on a gynaecological subject or case investigated during the period of gynaecological clerking.

M.D.—An ordinary candidate for this degree must be an M.B., Ch.B. of not less than one year's standing. He presents an original thesis for approval, and then passes a general examination in the principles and practice of medicine. From the latter the Board of Examiners may exempt a candidate whose thesis is of exceptional merit. The regulations respecting the Ch.M. are of the same general character. Subject to certain requirements as to special research or other post-graduate study, graduates of other universities may obtain the M.D. and Ch.M. in the same way as holders of the Birmingham M.B., Ch.B.

The degree of M.D. (State Medicine) is open to M.B., Ch.B. graduates of the university who possess also a diploma in public health or degree in sanitary science or public health recognized by the university. The period of post-graduate study for this degree must occupy one year in the case of Birmingham M.B., Ch.B. graduates, and two years in the case of graduates of other universities.

The degree of Ph.D. is open to qualified medical practitioners under special conditions applicable in the Faculty of Medicine. Under these regulations the necessary attendance and research during a period of two years may be carried out in the laboratories of the university or in associated hospitals.

FEES

The fee for Matriculation is £2 (payable to the Joint Matriculation Board); £2 10s. for First M.B. Examination (if taken in university); and £2 10s. for each of the first four Professional Examinations; M.B., Ch.B. degree fee, £10; M.D. and Ch.M. Examinations, £12 10s. each. For further particulars application should be made to the Registrar or the Dean of the Medical Faculty, University of Birmingham, Edmund Street.

UNIVERSITY OF BRISTOL

In the Faculty of Medicine the following degrees are conferred: Bachelor of Medicine and Bachelor of Surgery (M.B. and Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Dental Surgery (B.D.S.), and Master of Dental Surgery (M.D.S.). There are also the following diplomas: diploma in public health (D.P.H.), diploma in dental surgery (L.D.S.), and diploma in veterinary State medicine. All candidates for degrees in medicine, surgery, and dentistry are required to reach matriculation standard in the school certificate examination, or to pass such examination as may be regarded as equivalent by the Senate. All courses, degrees, and diplomas are open to men and women alike.

Conjoined Degrees of Bachelor of Medicine and Bachelor of Surgery.—Candidates must be not less than 21 years of age and have pursued the courses prescribed by university regulations during not less than five years after passing the First Examination in chemistry and physics, and entry upon professional study at a medical school, of which three shall have been spent in the university, and two of these three subsequent to passing the Second Examination. All candidates for the degrees of M.B., Ch.B. are required to satisfy the examiners in the several subjects of three examinations.

The First Examination.—The subjects of examination are: chemistry (inorganic), physics, and biology, the courses pursued being those for the time being approved for the intermediate part of the B.Sc. curriculum. This part of the curriculum shall extend over one year. (Candidates who have passed the higher school certificate approved by the Board of Education in these subjects will not be required to sit for the First Examination and will be regarded as having completed one year of study.)

The Second Examination.—The subjects of examination are: organic chemistry (Part I) and anatomy and physiology (Part II).

The Final Examination.—The subjects of examination are: materia medica and pharmacy, pharmacology and therapeutics, general pathology, morbid anatomy, and bacteriology (Part I); special pathology, forensic medicine, toxicology, and public health, obstetrics (including diseases of women), surgery (systematic, clinical, practical, and operative, including ophthalmology and oto-rhino-laryngology), medicine (systematic, clinical, and practical, including mental diseases) (Part II). The subjects included in Part II may be taken in two groups—namely, Group I: surgery and obstetrics; Group II: medicine, public health, special pathology, forensic medicine, and toxicology. Candidates may pass Parts I and II together or separately, and the two groups of Part II may likewise be taken together or separately, but no student can obtain honours who elects to take the two groups of Part II separately. Forensic medicine and toxicology may be taken either with Part I or with Group II of Part II.

Degree of Doctor of Medicine.—Candidates must be Bachelors of the university of not less than two years' standing as such, and may elect either (1) to pass an examination in general medicine; or (2) to pass an examination in State medicine, or (3) to present a dissertation. The candidate who elects to pass the examination in State medicine must hold a diploma in public health of some university or college, and the candidate who elects to present a dissertation may be examined in the subject thereof.

Degree of Master of Surgery.—The degree may be taken in general surgery or in special subjects. Candidates shall be Bachelors of the university who have practised for two years in an approved hospital (including the holding of an approved appointment for six months), and one of the two years shall have been spent in a hospital with a medical school attached. They shall present a dissertation and pass an examination. For general surgery, the examination shall include a written examination in surgery, a written examination in surgical anatomy and surgical pathology, a clinical examination, an oral examination, and an examination in operative surgery. For special subjects—that is, ophthalmology or oto-rhino-laryngology or gynaecology—the examination shall include

UNIVERSITY OF DURHAM

THE BRITISH
MEDICAL JOURNAL

a written examination in the anatomy, physiology, and pathology of the region of the body concerned (including in the case of ophthalmology, physiological optics), and a written examination in general surgery together with a written, oral, and clinical examination in the particular branch of surgery concerned, as well as an examination in operative surgery of the region concerned.

Diploma in Public Health.—Candidates must be at least 23 years of age, be fully registered medical practitioners of not less than two years' standing as such, and have passed the examination prescribed by regulation. The examination is divided into two parts.

and the candidate must submit evidence of having so worked. Not less than six months of another year must be spent as a resident surgeon in a recognized teaching hospital, and the rest of the year in the study of surgery in a recognized medical centre. Not less than six months of one of the three years must be spent in surgical study abroad.

The Degree of Bachelor of Hygiene and the D.P.H.

A period of not less than two years must elapse between the attainment by a candidate of a registrable degree or qualification in medicine, surgery, and midwifery and his admission to the final examination as the degree of B.Hy. or for the D.P.H. of the University as the case may be. The curriculum extends over a period of not less than twelve calendar months (or an academic year of whole-time study covering a period of not less than nine calendar months) subsequent to the attainment of a registrable degree or qualification. Candidates for the B.Hy. must take out the curriculum for Part I of the examination at the University of Durham, but for the D.P.H. may do so either at the university or at any medical school or institution recognized by the university. The examination is divided into two parts. Part I is practical, written, and oral, and includes the subjects of bacteriology and parasitology (including immunology, serology, medical entomology, etc.) especially in their relation to diseases of man, and to those diseases of the lower animals which are transmissible to man; chemistry, physics, radiology, and electrology in relation to nutrition and hygiene; and meteorology and climatology in relation to public health. The subjects in Part II include the principles of public health and sanitation; sanitary law and administration (including public medical services); sanitary construction and planning; and public health administration. This part of the examination is written and oral, and includes practical examinations in infectious diseases; food inspection; inspection of premises, dwelling-houses, factories, workshops, schools, etc. Candidates are not admitted to examination in either part until after they have completed the prescribed courses of instruction in the required subjects.

Doctor of Hygiene

Candidates for the degree of Doctor of Hygiene must be Bachelors of Hygiene of the university of two years' standing, and are required to satisfy the examiners that they have conducted original research in the subject of public health.

Diploma in Psychiatry

Candidates must be registered medical practitioners, and, unless qualified before January 1st, 1911, must have attended, subsequent to passing their qualifying examinations, courses of instruction in: (a) anatomy; (b) physiology; (c) pathology; (d) bacteriology; (e) psychology; (f) clinical psychology; (g) clinical neurology; (h) clinical psychiatry. The examination consists of two parts, namely: (1) anatomy, physiology, pathology, and bacteriology; (2) psychology and clinical psychiatry. Candidates may present themselves for the whole examination or for either part separately.

FEES

The following fees are payable: Matriculation, £2; Examinations, Pre-registration, £3 3s.; First, Second, and Third M.B., B.S., each £5; Final M.B., B.S., £15; M.D. and M.S., each £5; B.Hy. and D.P.H., £12 12s.; D.Psy., £10 10s.; and D.Hy. and D.Ch., each £20; First, Second, and Third L.D.S., each £3 10s.; and Final L.D.S., £5; First, Second, and Third B.D.S., each £5; Final B.D.S., £8; and M.D.S., each £6 6s. plus the sum of 10s. if it is the initial degree taken in the university; M.S. and M.D.S., each £6 6s.; M.D., D.Ch., and D.Hy., each £10; D.P.H., D.Psy., and L.D.S., each £3.

Further information may be obtained from the Dean of the College, University of Durham College of Medicine, Newcastle-on-Tyne.

UNIVERSITY OF LEEDS

The degrees granted in the Medical Faculty of this university are Bachelor of Medicine, Bachelor of Surgery (M.B. and Ch.B.), and Bachelor of Dental Surgery (B.Ch.D.), Doctor of Medicine (M.D.), Master of Surgery (B.Ch.D.), Master of Dental Surgery (M.Ch.D.), and diplomas in public health, in psychological medicine, in dental surgery, and in nursing.

UNIVERSITY OF DURHAM

To its own undergraduates, who may be of either sex, this university grants the degrees of Bachelor of Medicine and Bachelor of Surgery (M.B., B.S.), and also grants the higher degrees of Doctor of Medicine (M.D.), Master of Surgery and Doctor of Surgery (M.S.), and Bachelor of Hygiene, Doctor of Hygiene (M.S.), Surgery (B.D.S. and M.D.S.); it also grants diplomas in public health, psychiatry, and dental surgery. The university accepts the Durham University school certificate examination (if a sufficient standard is obtained in certain specified subjects) for matriculation purposes, but also accepts the tests of a considerable number of other educational bodies as a full or partial equivalent. A list may be obtained on application. In addition to satisfying the matriculation requirements of the university, every student must (1) pass a pre-registration examination in physics and inorganic chemistry conducted or recognized by the university, and (2) be registered on the books of the General Medical Council. The university requires that at least three years be spent in residence in the university; in certain cases candidates may obtain exemption from the First and Second Examinations, but the later professional examinations must be passed in the university.

Professional Examinations

There are four professional examinations for the M.B., B.S. degrees. The First Examination is held in March, June, and December; the Second and Third Examinations in March and June; and the Final Examination in June and December. The first deals with biology and chemistry in relation to medicine; the second with anatomy and physiology; the third with pathology, bacteriology, materia medica, pharmacology and pharmacy, medical jurisprudence, and public health. At the Final M.B., B.S. the candidate is examined in medicine, including therapeutics, and clinical medicine; surgery and clinical surgery; midwifery and diseases of women and children; clinical and practical midwifery, and gynaecology; and clinically in psychological medicine, diseases of the throat, nose and ear, diseases of the skin, diseases of the eye, and diseases of children.

M.D.—This degree is only open to Bachelors of Medicine of the university. They must be of at least two years' standing, and must comply with the regulations printed in the Calendar of the College of Medicine.

M.S.—Candidates for this degree must have been engaged in practice for at least two years subsequent to qualifying surgery, systematic and clinical, surgical anatomy and pathology, and surgical operations.

D.Ch.—The university grants also the degree of Doctor of Surgery. Candidates for this degree must be registered medical practitioners, not less than 24 years of age. They must devote three years, subsequent to obtaining a registrable qualification, to the study of surgery and ancillary subjects; one at least of the three years must be spent in the university. The candidate must submit to the professor of surgery the course of study he proposes to follow, and this course must be approved by the Board of Faculty of Medicine.

One year must be devoted mainly to work in the departments of anatomy, physiology, pathology, and bacteriology,

Candidates for the M.B. must have attended courses of instruction approved by the university for not less than five years, two at least of such years having been passed in the university, at least one year being subsequent to the date of passing the first examination. They must also have matriculated by satisfying the examiners in:

- I. Either English Composition and English Literature, or English Composition and History.
- II. Either Mathematics or Latin.
- III. } Three other subjects not already taken under I and II
- IV. } above, chosen from the following list:
- V. }

(1) English literature; (2) History; (3) Geography; (4) Greek; (5) Latin; (6) French; (7) German; (8) Some one other language approved by the Board; (9) Mathematics; (10) Mechanics; (11) Physics; (12) Chemistry; (13) General experimental science; (14) Natural history; (15) Botany.

Provided that (a) candidates who take Mathematics under II above must include one of the subjects 4-8; (b) candidates who take Latin under II above must include one of the subjects 9-15. In all cases Mathematics is a compulsory subject for admission to the Faculty of Medicine.

Exemption from the examination may be granted to applicants holding certificates of having passed examinations of a standard deemed by the Matriculation Board to be at least equal to the Board's examination.

Professional Examinations

The examinations for the M.B., Ch.B. number three.

The First Examination.—This consists of four parts (1) physics and inorganic chemistry, (2) organic and physical chemistry, (3) botany, (4) zoology, each of which may be taken separately, but candidates are not permitted to start their second year's work until Parts 1, 2, and 3 have been passed.

The Second Examination.—This consists of Part I, materia medica and practical pharmacy; Part II, anatomy and physiology. Candidates will be allowed to pass each part separately.

The Final Examination.—The Final Examination consists of: Part I, pharmacology and pathology and bacteriology; Part II, medicine, surgery, obstetrics and gynaecology; Part III, forensic medicine, public health, and therapeutics. Part I may be taken at the end of the second clinical year, and must be passed before Parts II and III are taken. Parts II and III may be taken at the end of the third clinical year but not before the completion of the fifth year of medical study. If taken separately Part III may not be passed before Part II.

M.D.—Candidates for this degree must be bachelors of medicine and bachelors of surgery of the university, and subsequently to having graduated must have completed two years of hospital practice or special study approved by the university; or four years in the practice of their profession in one or other of its various branches; six months' hospital practice or special study to count as the equivalent of one year's ordinary practice. Any subject of the medical curriculum except surgery may be chosen for the examination, but a thesis, the title of which must previously receive the approval of the Board of the Faculty of Medicine, may be submitted, and if it is adjudged to be of exceptional merit the candidate may be exempted from further examination.

Ch.M.—The candidate for this degree must have been admitted to the M.B., Ch.B. of the university not less than a year previously, and during that time must have held for at least six months a surgical appointment in a public institution affording full opportunity for the study of practical surgery. He must also have attended certain courses, including one on ophthalmology and one on pathology and bacteriology; he is then examined in surgery in all its branches and in ophthalmology and pathology and bacteriology.

FEES

The Matriculation fee is £2, and on readmission £2 or £2 2s. 6d.; for each of the other examinations £6 and £6 on readmission.

The fees for the M.D. and Ch.M. degrees are each £10 and the same on readmission. The fee for conferment of each of these degrees is £5.

UNIVERSITY OF LIVERPOOL

This university, besides granting degrees in medicine (M.B. and M.D.) and in surgery (Ch.B., M.Ch.Orth., and Ch.M.), awards degrees in dental surgery (B.D.S. and M.D.S.), and degrees in veterinary science (B.V.Sc., M.V.Sc., and D.V.Sc.). Diplomas are awarded in dental surgery (L.D.S.), tropical medicine (D.T.M.), tropical hygiene (D.T.H.), public health (D.P.H.), veterinary hygiene (D.V.H.), and medical radiology and electrology (D.M.R.E.). The degree of Doctor of Philosophy (Ph.D.) may also be taken in the Faculty of Medicine.

Matriculation

The matriculation examination is governed by the Joint Matriculation Board, 315, Oxford Road, Manchester, 13, which accepts, under certain conditions, the tests of several other bodies as its equivalent. Candidates will be required to have included mathematics among the subjects in which they have passed at such examination.

Professional Examinations

Candidates for the M.B., Ch.B. degrees have three examinations to pass, the first including (1) chemistry, (2) biology (zoology and botany), (3) physics.

Second M.B.—This test covers (1) anatomy, (2) physiology, including biochemistry and histology.

Final M.B.—The subjects of the Final Examination are: Part I—(a) pathology; (b) pharmacology and general therapeutics. Part II—(a) forensic medicine and toxicology; (b) public health. Part III—(a) obstetrics and diseases of women; (b) surgery, systematic, clinical, operative and practical, including ophthalmology; (c) medicine, systematic and clinical, including therapeutics, mental diseases, and diseases of children. Candidates may take Parts I, II, and III separately, provided that candidates may not present themselves for Part III until they have completed the sixth year of medical study and have passed the examinations in Parts I and II.

M.D.—May be conferred on graduates (M.B., Ch.B. Liverpool): (a) on candidates of two years' standing who present a thesis acceptable to the Faculty, and certified to be the candidate's own work, together with, if candidate desires, copies of published original papers upon medical science—oral examination on subject of thesis; (b) on candidates of five years' standing by examination in (a) Medicine and (b) a selected branch of Medicine.

Ch.M.—May be conferred on graduates (M.B., Ch.B. Liverpool) after examination. Other information concerning the diplomas of this university and its medical school will be found on page 418.

M.Ch.Orth.—May be conferred on graduates in Medicine of Liverpool or other approved university and graduates of a Faculty other than Medicine of Liverpool or other approved university who are Fellows of the Royal College of Surgeons of England, Edinburgh, or Ireland, or of the American College of Surgeons.

Fellowships, Scholarships, and Exhibitions

The university awards Fellowships annually to students of distinguished merit, as follows:

- (1) John Rankin Fellowships in Anatomy, two, each of the value of £120, tenable for two years.
- (2) Ethel Boyce Fellowship in Gynaecology, value £100 and tenable for one year, open to fully qualified medical students of either sex.
- (3) John W. Garrett International Fellowship in Bacteriology, value £100 and tenable for one year.
- (4) Robert Gee Fellowship in Human Anatomy, value £100 and tenable for one year.
- (5) Holt Fellowships in Physiology and Pathology, two in number, value £150 each and tenable for one year.
- (6) Johnston Colonial Fellowship in Biochemistry, value £100 and tenable for one year.
- (7) Thelwall Thomas Fellowship in Surgical Pathology, value £150 and tenable for one year.
- (8) Lady Jones Fellowship in Orthopaedic Surgery, one, value £200, offered every two years.

There are, in addition, scholarships and exhibitions open to medical students.

VICTORIA UNIVERSITY OF MANCHESTER

This university grants the four ordinary degrees in medicine and surgery—M.B. and Ch.B. and M.D. and Ch.M.; a degree and diploma in dental surgery; a diploma in public health; a diploma in psychological medicine; a diploma in bacteriology; and a diploma in pathology. Candidates for degrees must pass the special matriculation examination prescribed by the Faculty of Medicine (or some equivalent examination accepted in lieu thereof: see the prospectus of the Joint Matriculation Board), and study at the university itself for at least two years of the six years' curriculum, subsequent to the passing of the First M.B. Examination. The matriculation examination comprises (1) Latin, (2) mathematics, (3) the English language, its literature and history, (4) mechanics, (5) one subject at choice as approved by the Joint Board. It is held in July and September.

Professional Examinations

M.B., Ch.B.—There are four examinations for this degree. They must be passed in proper order, and before admission to them the candidate must be duly certified as having attended in the subjects involved. The First M.B. is divided into Part I, chemistry and physics; Part II, biology—(a) botany, (b) zoology. The parts may be taken separately or together. At the Second M.B. the candidate is examined in anatomy (including histology) and physiology; at the third in pathology, bacteriology, and pharmacology (including materia medica and practical pharmacy). The Final Examination is divided into two parts, which may be taken separately. Part I consists of (a) forensic medicine and toxicology, and (b) hygiene and preventive medicine. Part II consists of (a) medicine, including dermatology, diseases of children, and mental diseases; (b) surgery, surgical pathology, and diseases of the eye and of the ear, nose, and throat; (c) obstetrics and gynaecology.

M.D.—A candidate for this degree must be a Bachelor of Medicine of the university of at least one year's standing. He has a choice between presenting an original dissertation or undergoing a written (as well as a practical and clinical) examination in medicine, and a written and practical examination in pathology, and one other subject selected by himself.

Ch.M.—A candidate must have held, since becoming Ch.B., and for not less than twelve months, a post in a public institution affording opportunity for the study of the branch of surgery in which examination is desired. The examination in Branch I comprises the general field of surgery; Branch II, obstetrics and gynaecology; Branch III, ophthalmology; Branch IV, otology, laryngology, and rhinology.

B.Sc. and M.Sc.—The ordinary degree of B.Sc. in the Schools of Anatomy and Physiology may be obtained by students in medicine who in their third year of study for the degree of M.B., Ch.B. complete the additional courses in these subjects prescribed for this degree. Candidates for the Honours degree of B.Sc. in anatomy or physiology who are students in medicine are required to attend courses in advanced anatomy and physiology for four terms after passing the Second Examination for the degrees of M.B., Ch.B. Graduates in science of this university, of not less than one year's standing from the date of their graduation as Bachelors, may proceed to the degree of M.Sc. by the presentation of an approved thesis on some subject coming within the scope of the Faculty of Science.

FEES

The following examination fees are payable. Matriculation, £2; on readmission, £2. Each M.B. examination, £8 8s.; on readmission, £3 3s. M.D., including the conferring of the degree, £15 15s. Ch.M., £10 for the examination and £10 10s. for conferment of degree. Application for further information should be addressed to the Dean of the Medical School.

UNIVERSITY OF SHEFFIELD

The degrees of this university (M.B., Ch.B., M.D. and Ch.M., B.D.S., and M.D.S.), and the diploma of licentiate in dental surgery, are open to candidates of either sex. Candidates for a degree must have matriculated in the

university or have passed such other examination as may be recognized for this purpose, and have passed the preliminary examination in chemistry and physics.

Professional Examinations

A candidate for the degrees of M.B., Ch.B. must produce certificates that he will have attained the age of 22 years by the day of graduation; that he has pursued the courses of study required by the university regulations during not less than five and a half years subsequent to the date of his matriculation or exemption from matriculation, three of such years at least having been passed in the Faculty of Medicine of the university, one at least being subsequent to the passing of the Second Examination. The following examinations must be passed in due order.

First Examination.—The subjects are chemistry, physics, and biology. Candidates who have passed the Intermediate Examination of the Faculty of Pure Science in any or all of the subjects of the First M.B. Examination will, on payment of the fee for the latter examination, be deemed to have passed it when they have passed in such subjects as they did not take for the Intermediate B.Sc. Examination. Candidates on presenting themselves for this examination are required to furnish certificates of having attended for not less than one year approved courses of instruction, after matriculation, in (i) chemistry, inorganic and organic; (ii) physics; (iii) biology; and of having passed or obtained exemption from the preliminary examination in chemistry and physics.

Second Examination.—The subjects are anatomy and physiology (Part I). Candidates must have passed the First Examination, and must have attended (1) courses on anatomy, including lectures and practical anatomy, during five terms; (2) courses on physiology, including lectures and practical physiology, during one year.

Third Examination.—The subjects are pathology and pharmacology, applied anatomy, and physiology (Part II). Candidates must have attended courses of instruction in pathology for five terms, in pharmacology for three terms (and one term in pharmacy), in applied anatomy for four terms, and in physiology (Part II) for six terms.

Final Examination.—The subjects are: Part I, forensic medicine and public health; candidates must have attended courses for one term in each subject. Part II, medicine (including mental diseases and diseases of children and vaccination), special pathology (including morbid anatomy and clinical pathology), and therapeutics. Part III, surgery (including the administration of anaesthetics, diseases of the ear, nose, and throat, ophthalmology, and surgical pathology), and obstetrics and gynaecology (including ante-natal and post-natal practice and infant hygiene). Candidates for Parts II and III must have completed a minimum of five and a half years of study.

M.D.—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least three years previously, must present a thesis embodying observations in some subject approved by the Professor of Medicine, and must pass an examination in the principles and practice of medicine.

Ch.M.—Candidates for the degree of Master of Surgery must have passed the examination for the degrees of M.B., Ch.B. at least three years previously, and must, since taking the degrees of M.B., Ch.B., have held for not less than twelve months a surgical appointment in a public hospital or other public institution affording full opportunity for the study of practical surgery. The subjects of examination are systematic, clinical, and operative surgery, surgical anatomy, surgical pathology, and bacteriology.

Other information concerning this university will be found in the section devoted to Provincial Medical Schools.

UNIVERSITY OF WALES

The Charter and statutes of the University of Wales provide *inter alia* for a School and a Faculty of Medicine and for the granting of the following degrees: Bachelor in Medicine (M.B.), Bachelor in Surgery (B.Ch.), Master in Surgery (M.Ch.), and Doctor in Medicine (M.D.).

A candidate for the M.B., B.Ch. is required to pursue a course of study of not less than six academic years

subsequent to matriculation in the university, and of these years at least three must have been passed in one of the constituent colleges of the university. These are the University College of Wales, Aberystwyth; University College of North Wales, Bangor; University College of South Wales and Monmouthshire, Cardiff; and University College of Swansea. He must hold an arts or science degree of the University of Wales, or of some other university approved for this purpose. Certain of the courses of study pursued for a B.Sc. or a B.A. degree may be counted as courses required for the degrees in the Medical Faculty.

The courses for the M.B., B.Ch. are divided into two sections, of which the first includes the preliminary subjects—physics, chemistry, botany, zoology; and the ancillary subjects—organic chemistry, human anatomy, and physiology. Study of the preliminary subjects and of organic chemistry must extend over at least one academic year; study of physiology and anatomy must extend over at least two academic years; the first section of the course must occupy not less than three years.

The second section includes courses in pathology, bacteriology, pharmacology, hygiene and forensic medicine, medicine, surgery, and obstetrics and gynaecology, and cannot be commenced until the examinations relating to the preliminary and ancillary courses have been passed. Examinations in all the subjects are held in June of each year, and in pharmacology, pathology, medicine, surgery, obstetrics and gynaecology, in December also.

The university also provides courses of study in public health and in tuberculosis, and awards Diplomas in Public Health (D.P.H.) and Tuberculous Diseases (T.D.D.). Candidates for these diplomas must possess a medical qualification registrable for practice in Great Britain and Ireland, and must have completed courses of study as prescribed by the regulations.

Further particulars and prospectuses may be obtained from the Secretary, Welsh National School of Medicine, The Parade, Cardiff.

Welsh National School of Medicine

This school was reconstituted under the provisions of a Royal Charter granted to the school in February, 1931. The school maintains departments of medicine, surgery, obstetrics and gynaecology, pathology and bacteriology, materia medica and pharmacology, tuberculosis, and preventive medicine and public health.

Full particulars of the conditions of admission to the school and the courses of instruction provided may be obtained on application to the Secretary, Welsh National School of Medicine, The Parade, Cardiff.

English Medical Corporations

There are in England three medical corporations which grant licences to practise—the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. The first two combine for certain purposes to form what is known as the Conjoint Board in England. Details concerning this body, its component Colleges, and the third licensing body here follow.

THE CONJOINT BOARD

This body—the Examining Board in England—deals with the qualifications of all candidates for the Licence of the Royal College of Physicians of London and for the Membership of the Royal College of Surgeons of England. It prescribes for them certain periods of study, and recommends those who pass the required examinations for the Licence and for the diploma of Member respectively. The successful candidate is then entitled to register as L.R.C.P.Lond., M.R.C.S.Eng. It performs the same task in connexion with diplomas in public health, tropical

medicine and hygiene, ophthalmic medicine and surgery, psychological medicine, laryngology and otology, gynaecology and obstetrics, and medical radiology, jointly issued by the two Colleges. Under the present regulations every candidate for the L.R.C.P. and M.R.C.S. must (1) complete five years of professional study after passing a recognized preliminary examination and a recognized pre-medical examination in chemistry and physics; (2) comply with the regulations, which may be had from the Secretary, Examination Hall, Queen Square, London, W.C.1; and (3) pass the two professional examinations of which particulars appear below.

Regulations for the Conjoint Diplomas

The following is an outline of the present regulations for the L.R.C.P.Lond. and M.R.C.S.Eng. The full regulations and synopses and forms of certificate may be obtained from the Secretary.

Pre-Medical Examination

Students are required to pass a pre-medical examination in chemistry, physics, and elementary biology, conducted by the Conjoint Examining Board, before commencing the five years' curriculum of professional study, or some other examination recognized by the Board—namely, the examination in chemistry, physics, and biology for the degree in Medicine of any university recognized by the Board, the higher school certificates of Oxford and Cambridge Universities and the Oxford and Cambridge Schools Examination Board, the higher certificates of London, Bristol, Durham Universities, the Joint Matriculation Board of the Northern Universities, or the Central Welsh Board higher certificate.

A candidate must enter for chemistry and physics together, and he will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other subject. He will be admitted to the examination on producing evidence of having passed the required preliminary examination in general education.

The examination is partly written, partly oral, and partly practical. A candidate rejected in one or both subjects of the examination will not be admitted to re-examination until after the lapse of a period of not less than three months. Not more than two terms of professional study is recognized before the examination in elementary biology is passed.

Professional Examinations

There are two professional examinations, called the First and Final Examinations. The courses of study for the First Examination may be commenced before the pre-medical examination has been passed provided three terms of study of anatomy and physiology are completed after passing such examination.

First Professional Examination.—The subjects of this are: Section I, (a) Anatomy, including histology and embryology; (b) physiology, including biochemistry. Section II, Pharmacology and materia medica. A candidate must have attended at a recognized Medical School courses of instruction in anatomy, including embryology, during five terms, in the course of which he must have dissected the whole body; courses of instruction in physiology, including biochemistry and biophysics, during five terms; courses of instruction in pharmacology and materia medica. A candidate may present himself for the two sections together or separately, but he must take parts (a) and (b) of Section I together until he has passed in one or both parts, but a candidate will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part. Section II of the examination may be passed at any time before the candidate enters for the Final Professional Examination, provided that the courses for admission to Section I have been completed. A candidate who produces satisfactory evidence of having passed an examination in the subjects of Section I or of either part of Section I and of Section II in the examination for the degree in Medicine conducted at a university recognized by the Board will be exempted from further examination in such subject or subjects.

Final Professional Examination.—The subjects of this are: Section I, Pathology (including morbid anatomy, morbid histology, and clinical pathology) and Bacteriology. Section II, Part I, Medicine, including medical anatomy, forensic medicine, and public health; Part II, Surgery, including surgical anatomy and the use of surgical appliances; Part III, Midwifery and gynaecology. The examination is partly written, partly practical, partly clinical, and partly oral. A candidate may take Sections I and II and the three parts of Section II

of the Final Examination separately, or may take the whole examination together. He will be required to produce the certificates prescribed by the regulations before being admitted to the respective parts of the examination. No exemption is granted from any subject in the Final Examination.

FEEs

The fee for the *Pre-Medical Examination* is four guineas, for re-examination in Chemistry two guineas, for re-examination in Physics one guinea, and for Biology one guinea. The fee for the *First Professional Examination* is ten guineas, for re-examination after rejection in Section I six guineas, for re-examination after rejection in either part of Section I three guineas, for re-examination after rejection in Section II three guineas. The fee for admission to Section I of the *Final Professional Examination* is four guineas; for admission to Section II, Part I, ten guineas; Part II, ten guineas; Part III, six guineas; and the re-examination fees are respectively three guineas, six guineas, six guineas, and five guineas.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

This College has three grades—its Licentiate, its Members, and its Fellows. The Licence is now only issued through the Conjoint Board. The Membership (examinations for which are held in January, April, July, and October) is only granted to those who have obtained the Licence or to those who are graduates of a recognized university; in any case they must be persons over 23 years of age. Candidates are examined in pathology and the practice of physic, partly in writing and partly *viva voce*; they are also examined in Latin, Greek, French, and German. The languages are not compulsory, but credit is given to those who show a knowledge of them. The fee for the Membership is £42, or in the case of a Licentiate £21. There is a fee of £10 10s., payable before entrance to the examination, which in the case of successful candidates is reckoned as part of the Membership fee. The body of Fellows is maintained by election from among the Members.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

This College has two grades—Members and Fellows. The Members are admitted as stated in the section dealing with the Conjoint Board. The Fellowship is granted after examination to persons at least 25 years of age who have been engaged in professional studies for six years. There are two examinations for the Fellowship—the first in anatomy and physiology, held in the months of June and December, which may be passed after the third winter session; the second held in the months of May and November, chiefly directed to surgery, which may be passed after six years of professional study. Candidates must pass the Final Examination of the Examining Board in England and be admitted Members of the College before admission to the Second Examination for the Fellowship, except in the case of graduates in medicine and surgery of not less than four years' standing of universities recognized by the College for the purpose. All candidates are required to have held for six months a responsible post in charge of general surgical patients in the wards of a general hospital recognized by the Council.

Fees.—At First Examination, £8 8s.; for re-examination, £5 5s. At Second Examination, £12 12s. Admission fee £10 10s. for members, £31 10s. for non-members.

THE SOCIETY OF APOTHECARIES OF LONDON

This Society confers a registrable diploma in medicine, surgery, and midwifery, now known as the L.M.S.S.A. (Licentiate in Medicine and Surgery of the Society of Apothecaries), on those successful at the following examinations:

Pre-medical Examination.—Chemistry and physics, and elementary biology.

Primary Examination.—This includes anatomy, physiology and histology, written, oral, and practical, and

materia medica and pharmacy, written and oral. Candidates referred will be required to produce evidence of further study before being admitted to re-examination. Candidates will be excused any or all the subjects of the Pre-medical and Primary Examination on producing evidence that they have passed the equivalent examinations before an examining body recognized by the Society.

Final Examination.—This is divided into four sections: A, Principles and practice of surgery, including surgical pathology, surgical anatomy, operative manipulation, instruments and appliances; B, Principles and practice of medicine (including therapeutic prescriptions), general and medical history, and morbid histology; C, diseases of newborn children, obstetric instruments and appliances; D, Forensic medicine, hygiene, theory and practice of vaccination, and mental diseases. A, B, and C are written, oral, and clinical. D is written and oral. A, B, C, and D may be taken at separate examinations, but there is no exemption from any subject of the Final Examination. Candidates referred in A, B, or C will be required to produce evidence of further study before re-examination.

All candidates making their first entry for the Final Examination after January 1st, 1935, will be required to pass the present Section D (forensic medicine, hygiene, and mental diseases) with Section B (medicine, general pathology, and bacteriology). The sections which may be taken separately will therefore be: A (surgery), B and D (medicine, etc.) C (midwifery). The form and scope of the examination will otherwise be unchanged.

The fee for the Pre-medical Examination is £5 5s.; for the Primary and Final, £21. The regulations and synopses relating to the several examinations, and other information, may be obtained from the Registrar, the Society of Apothecaries, Water Lane, Queen Victoria Street, E.C.4.

Mastery of Midwifery

The Society has recently instituted a Mastery of Midwifery, and issues a diploma under this title denoting the possession of specialized knowledge of ante-natal care, midwifery, and child welfare. The examinations take place in May and November, and candidates are required to submit certificates, etc., twenty-one days before date of examination. A severe test has been imposed so as to ensure a high standard of professional knowledge, but the diploma is not registrable under the Medical Acts. Admission is open to all who have been for not less than three years in possession of a registrable medical qualification, and who have had certain prescribed experience at recognized institutions concerned with obstetrics, ante-natal work, and child welfare work. Medical officers employed by a public health authority, and having special duties connected with maternity and child welfare, are admitted to the examination on production of evidence to that effect. The entrance fee for the examination is £10 10s., and a further fee of £10 10s. is payable by successful candidates before admission to the Mastery. Copies of the regulations may be obtained from the Registrar at the address given in the preceding paragraph.

British College of Obstetricians and Gynaecologists

The British College of Obstetricians and Gynaecologists was founded and incorporated in September, 1929. The objects of the College are set forth in the Memorandum of Association. The first and most important object is "to encourage the study and practice of obstetrics and gynaecology, subjects which should be inseparably interwoven." The College consists of Fellows and Members. It also has power to grant diplomas and certificates in obstetrics and gynaecology, either alone or in co-operation with teaching and/or examining bodies authorized to grant such diplomas. Candidates for the Membership of the College have to show evidence of having held resident appointments in general medicine or surgery, as well as in obstetrics and gynaecology, before

entering for the examination. The Fellowship of the College is granted to those Members who are judged by the College to have advanced the science and art of obstetrics and gynaecology. The Fellowship and Membership of the College include practically every teacher of obstetrics and gynaecology in Great Britain, and many distinguished exponents in the British Dominions. The Fellowship or Membership of the College is now a necessary qualification for election to the staff of several obstetric and gynaecological hospitals, and it is hoped that in time it will be regarded as essential for election to the staff of such hospitals. Consequently, all intending to specialize in these subjects should endeavour to obtain as soon as possible the Membership, the conditions and regulations of which may be obtained from the honorary secretary. The president is Dr. J. S. Fairbairn, the treasurer Mr. Eardley L. Holland, and the honorary secretary Professor W. Fletcher Shaw.

After long consideration, and as the result of over three years' experience gained by its Examination Committee, the College, recognizing that the present training of students in obstetrics is insufficient to fit them for responsible work in maternity services, has decided to award a diploma (D.C.O.G.) to registered medical practitioners who have had special post-graduate training and experience in the subject and satisfy the examiners appointed by the College. The membership of the College, being intended for those aspiring to special practice in obstetrics and gynaecology, demands a larger and wider experience than is possible for those entering family practice. Many candidates for the membership have had to be rejected because they had insufficient training and experience, and for most of these candidates it is impossible, at the stage of their career which they have reached, to undergo further training and to hold further resident posts. Many of them will be suitable candidates for the diploma. A special regulation has been made for candidates whose names have been on the *Medical Register*, and who have been engaged in practice for at least ten years. Copies of the prospectus and regulations for the membership and diploma may be obtained from the secretary of the College, 58, Queen Anne Street, W.1.

Scotland

THE UNIVERSITIES

There are in Scotland four universities, each possessing a Faculty of Medicine, and having the right to confer degrees which admit the holder to the *Medical Register*. In essential points the regulations in their medical faculties for undergraduates are much alike, so that a general account can be given of all of them together.

The universities are those of St. Andrews, Glasgow, Aberdeen, and Edinburgh. The provision each of the cities in which these universities are situated makes for the education of medical students will be found in the section on Medical Schools in Scotland; here it need merely be said that degrees in medicine from Scotland as a whole have always enjoyed a high repute.

The degrees granted in medicine and surgery to candidates of either sex are four in number—Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.). The two former are not obtainable one apart from the other. Besides these degrees a diploma in tropical medicine and hygiene is obtainable from the University of Edinburgh, as also diplomas in psychiatry and radiology. As for public health, registrable degrees and diplomas in this subject are granted by the University of Glasgow, while diplomas in public health may be obtained from the Universities of Edinburgh, St. Andrews, and Aberdeen.

The conditions for admission of graduating students of medicine are the same as those in the Faculties of Arts

or Science. Prospective medical students are also required to pass a pre-registration examination in chemistry and physics. This is not enforced at Aberdeen or St. Andrews.

Professional Education

The regulations comply in all respects with the requirements and recommendations of the General Medical Council, and, in addition, necessitate definite study for stated periods of diseases of children, of the larynx, ear, and nose, of the skin, of ophthalmology, and of mental diseases. In respect of the various courses certificates must be obtained showing that the student has not only attended regularly, but has duly performed the work of the class. Out of the necessary five years of medical study not less than three (or in certain circumstances two) must be spent at the university whose degrees the student hopes to obtain, and the balance at any place officially recognized for such purpose. In each academic year there are two sessions—one lasting from the beginning of October to the middle of March, and the other from the middle of April to the beginning of July.

Professional Examinations

The distinctive feature of the Scottish curriculum is that though nominally there are only four examinations, each of these may be, and habitually is, split up by the student into sections. Hence, a student may complete some stage of his career during the course of nearly every session. Thus, by the end of the first winter session the student may pass in zoology* and chemistry.† At the end of the first summer session he can finish with botany* and physics,‡ and with anatomy and physiology at the end of the second. Pathology and materia medica he may pass at the end of the third year, and so on, until the final examination in midwifery, surgery, and medicine, and the corresponding clinical subjects, at the end of the fifth year of study. At each examination the candidate may pass "with much distinction" or "with distinction," and a record is kept of the merit displayed, so that when the time comes for the candidate to graduate, one who has done well throughout can be declared as graduating with honours. A further point in the system is that the student's own teachers commonly take some part in his examination.

Of the four examinations, the first deals with physics, botany, zoology, and chemistry; the second with anatomy and physiology; the third with materia medica and pathology; the fourth with medicine and surgery (clinical and systematic), midwifery, clinical midwifery and clinical gynaecology, and forensic medicine and public health. At Edinburgh the first two examinations are held three times a year; the third and final twice a year. At St. Andrews all four examinations are held twice a year, and at Glasgow the first two are held twice a year and the third three times. At Aberdeen, degree examinations in all subjects are held twice a year.

Exemption from the first professional examination may be obtained by candidates who have passed an arts, science, or medical degree examination in its subjects at any recognized university.‡

The Higher Degrees

It is open to those who are already M.B., Ch.B. to proceed either to the M.D. or the Ch.M. A candidate for the former must have been engaged for not less than one year in work in the medical wards of a hospital, or in scientific research in a recognized laboratory, or in the Naval or Military Medical Service, or have been at least

* At St. Andrews University botany and zoology may be taken at the end of the first winter term, physics and chemistry at the end of the first year.

† In the case of Glasgow these subjects—chemistry and physics—are transposed.

‡ This does not apply to the University of Aberdeen, where the course in physics includes special instruction on the medical aspects of the subject. Accordingly every student, irrespective of whether he holds an arts or science pass in physics, must take medical physics.

two years in general practice, and he must be 24 years of age. He has to write a thesis on any subject not exclusively surgical, and is examined in clinical medicine and (or, in the case of Glasgow, St. Andrews, and Aberdeen) in some one or other of its special departments. The regulations for candidates for the Ch.M. are of a corresponding character, a period of surgical work in a hospital or elsewhere being substituted for medical work, and the thesis being on a surgical rather than a medical subject. He is examined in surgical anatomy, clinical surgery, operative surgery, and in some of the special departments of surgery.

FEES

It is estimated that the class, examination, and other fees for the M.B., Ch.B. come altogether to about £265, the separate examination fees included in this calculation being as follows:

	£	s.	d.
First Professional	9	9	0
Second Professional	7	7	0
Third Professional	6	6	0
Final	11	11	0

Re-entry in any subject in which the candidate has failed entails a fresh payment of £1 1s. Candidates for the M.D. and Ch.M. pay £21, and on re-entry £5 5s.

More detailed information with regard to the University of Edinburgh can be obtained from the *Medical Programme*, price 6d., which is published by Mr. Thin, 55, South Bridge, Edinburgh, or on application to the Dean of the Faculty of Medicine. Similar information about Glasgow should be sought from the Assistant Clerk, Matriculation Office, Glasgow. With regard to Aberdeen, application should be made to the Secretary of the University of Aberdeen. In respect of St. Andrews, information can be obtained either from the Secretary of the University, or, alternatively, the Secretary of the United College, St. Andrews, or the Secretary of University College, Dundee, these being the two constituent colleges of the University of St. Andrews.

Finally, it should be mentioned that in connexion with all the Scottish universities there are valuable bursaries and scholarships, some information as to which will be found in the article on Medical Schools.

The Carnegie Trust

The following is a summary of the regulations made by the Carnegie Trust for the Universities of Scotland for assistance in the payment of class fees in the universities and extra-mural colleges of Scotland.

Applicants must be over 16 years of age; they must be of Scottish birth or extraction, or have attended for two years, after the age of 14, at a school or institution under inspection of the Scottish Education Department. Applicants so qualified who have been pupils of schools under the Scottish Education Department will be eligible for assistance in the payment of class fees if they have obtained the leaving certificate of the Department with a minimum of three higher grade passes, provided that it bears evidence of such preliminary education as is required by the universities for their graduating curricula, or that it has been supplemented by such passes either in the Scottish Universities Preliminary or other examination as will satisfy the above requirement of the universities. Where applicants have not been pupils of schools under the Scottish Education Department, or where other good ground for not having obtained the leaving certificate can be shown, the Executive Committee has power to accept instead what it deems equivalent evidence of attainments provided that applicants will not be considered eligible who have not obtained three higher grade passes or who require to pass any further preliminary examination before they can complete their graduating curricula. No applicant in medicine is eligible for assistance until pre-registration subjects have been passed at any centre where pre-registration examinations are required.

Applicants in the Faculties of Arts and Science must have had their course of study for each academic year approved by the University Adviser of Studies, and all applicants must have passed the graduation examinations belonging to the previous stage of their curriculum before becoming eligible for assistance in the payment of fees of classes belonging to a further stage. Beneficiaries must submit to the Executive Committee at the end of each session particulars as to their

attendance and work, any distinctions gained, and any graduation examinations passed.

The annual allowance towards payment of class fees offered to beneficiaries by the Trust in the Faculty of Medicine is £20 for four years, in all £80. Any unexpended part of a grant will be carried forward to the succeeding year. In combinations of Faculties the allowances available for beneficiaries are: Arts and Medicine—two Arts grants of £9 and four Medicine grants of £20, in all £98; Science and Medicine—two Science grants of £18 and four Medicine grants of £20, in all £116.

Applicants, in writing for application forms (Carnegie Trust, Merchants' Hall, 22, Hanover Street, Edinburgh) must name the university and faculty in which they intend to study, and state whether they have previously obtained the benefits of the Trust. Applications must be lodged not later than October 25th for the winter session, or May 10th for the summer session. Payments are made by means of fee coupons, and fees already paid are not refunded.

THE SCOTTISH CORPORATIONS

There are three medical corporations in Scotland—the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Their licences can be separately obtained only by persons who are already in possession of a recognized qualification—in surgery in the case of the College of Physicians, and in medicine in the case of the College of Surgeons and the Faculty of Physicians and Surgeons of Glasgow. All others must submit to the examinations held by the Conjoint Board, which the three corporations have combined to form. Details concerning this Board and its component Colleges follow. The conditions on which their higher qualifications are granted will be found set forth separately in connexion with each corporation.

THE CONJOINT BOARD IN SCOTLAND

This body has charge of all questions connected with candidates for the Conjoint Licences of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Those finally approved by it are entitled to registration and to the initials denoting the Licences of the three bodies concerned—namely, L.R.C.P.Ed., L.R.C.S.Ed., and L.R.F.P.S.Glas. The Board requires all candidates to comply with the regulations of the General Medical Council. It has an arts examination of its own, but is prepared to accept in its place any of the other educational tests approved by the General Medical Council. All candidates must obtain registration with the General Medical Council.

Professional Curriculum for Candidates registered as Medical Students after October 1st, 1930

Subsequent to registration as a medical student the candidate must pass not less than five years in medical study, each comprising a winter and a summer session. The Board does not insist that candidates shall pursue their study at any particular place, and is prepared to accept certificates of having attended the necessary courses from any recognized medical school.

Its examinations are four in number, each of them being held four times every year, and these will fall to be held three times in Edinburgh and once in Glasgow during the next period; it is open to candidates to present themselves for examination at either place. The first examination deals with general biology (systematic and practical), and physics and chemistry (systematic and practical); the second with anatomy, embryology, physiology, biochemistry and biophysics; the third with pathology (including bacteriology and morbid anatomy) and pharmacology (theoretical and practical); and the final with (1) medicine, including therapeutics, applied anatomy and physiology, and clinical pathology, with practical medicine; (2) surgery, including applied anatomy and physiology, clinical

pathology, and practical surgery; (3) midwifery and diseases of women, clinical obstetrics and gynaecology, with practical midwifery; and (4) medical jurisprudence and public health. All candidates for the Final Examination must complete portions (1) (2) and (3), which must be taken together, within a period of nineteen months.

These examinations must be passed in due order, and before admission to any of them the candidate must supply certificates showing that he has completed the due periods of study of their subjects. He can present himself in any single subject of the first three examinations. As regards the Final Examination, a candidate can present himself in medical jurisprudence and hygiene at any time after completion of the third examination and of his study of these subjects; but in medicine, surgery, and midwifery he cannot present himself until the completion of five years' study, and he must take them all simultaneously. A candidate who takes up several subjects of an examination or the whole of the subjects at one time, but fails in some of them, is credited at the next examination with those subjects in which he has been approved.

Part or entire exemption from the first three examinations may be granted to those who have already passed before other bodies examinations deemed by the Board equivalent to its own, but all candidates for the Conjoint Licence must sit for the Final Examination, and at no examination can a candidate present himself within three months of his rejection by some other licensing body.

FEES

It is estimated that the total cost of lectures and fees for the Conjoint Licence is about £170. The separate examination fees are as follows: First, Second, and Third Professional, £5 each; Final £15. On re-entry for any of the first three examinations £3, and on re-entry for the Final, £5. If the re-entry is only in one or two subjects of the First, Second, or Third Examination the fees are smaller.

Information concerning this Board should be sought either from Mr. David Thomson, Solicitor, 18, Nicolson Street, Edinburgh, or from Mr. David Willcox, Faculty Hall, 242, St. Vincent Street, Glasgow.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

This College has three grades—Licentiate, Membership, and Fellowship—all of which are open to men and women. The regulations applying to candidates for the Licentiate have already been generally indicated. If desirous of receiving it apart from those of the other two corporations, they must be duly registered medical practitioners. Candidates will be required to pass an examination corresponding to the medical part of the Final Examination of the Conjoint Board, and conditioned in the same way, and also an examination in materia medica. The fee for examination is 15 guineas, a special examination being obtainable on due cause being shown, and on payment of 5 guineas extra. Ordinary examinations take place monthly on the first Wednesday and Thursday, except in September and October.

Candidates for the Membership must be either Licentiates of a British or Irish College of Physicians, or alternatively graduates of medicine of a university approved by the Council, and in either case not less than 24 years of age. Candidates are examined in medicine and therapeutics, also on one or more departments of medicine specially professed, and approved by the Council, in which a high standard of proficiency will be expected. The fee to be paid by a candidate for the Membership is £36 15s. The examination is held quarterly, on the second Tuesday and following days of the months of January, April, July, and October, and application for admission to it must be made a month previous to the date at which it is proposed to appear.

For the Fellowship the candidate must have been a Member of the College for at least three years, and, if accepted, pay fees, including £25 stamp duty, amounting altogether to £64 18s. Further details can be obtained on application to the Secretary of the College.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

This College has two grades—its Licence and its Fellowship. Licentiates may be of either sex, and for the Fellowship women are eligible also.

Licence

As an original qualification the Licence is only granted after fulfilment of the regulations of the Scottish Conjoint Board, but as an additional qualification it can be obtained by those already possessed of a registrable or equivalent qualification in medicine. In this case the candidate has to pass a written, oral, and clinical examination in surgery and surgical anatomy, and may be asked to operate on the dead body.

The fee is £15 15s., of which £10 10s. is returned to unsuccessful candidates. On due cause being shown, a special examination may be granted, the fee being £20, of which £10 is returned to a candidate if he is not approved.

Fellowship

Candidates for the Fellowship must be not less than 25 years of age, and have been in the practice or study of their profession subsequent to qualification for at least two years, and must hold either a surgical degree from a university recognized for that purpose by the College, or a registrable diploma obtained as the result of an examination which includes surgery as well as medicine and midwifery. Candidates are examined in (a) the principles and practice of surgery, including surgical anatomy, (b) clinical surgery, and (c) one optional subject, which they may choose from among the following: surgical pathology and operative surgery, ophthalmology, laryngology, otology and rhinology, surgery, anatomy, and dental.

The examination is written, oral. A candidate who desires to be examined must give one month's notice. After having passed the examination he must lodge with the Clerk to the College a petition asking that his name be placed before the College for election as a Fellow. This petition must be signed by two Fellows, as proposer and seconder, who should be sufficiently acquainted with the candidate to vouch that he is in every way a suitable candidate for the Fellowship. Examinations are held four times a year—January, March, July, and September. It is desirable that either the proposer or the seconder should be resident in Edinburgh. Candidates are not allowed to appear more than three times at the examinations unless by express permission of the President's Council.

The admission fee is £20, and after passing the examination the candidate shall pay the sum of £30 to the College funds. In the case of Licentiates of the College £10 thereof shall be remitted in consideration of the fees they have already paid. For further information application should be made to the Clerk of the College, Mr. David Thomson, Solicitor, Surgeons' Hall, 18, Nicolson Street, Edinburgh, from whom a copy of the *Laws Relating to the Fellowship by Examination* may be obtained.

ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

This body possesses two classes—Licentiates and Fellows. The regulations applying to the former correspond with those respecting candidates for the Licence of the Royal College of Surgeons of Edinburgh. Candidates for the single Licence are examined in surgery (including clinical surgery and surgical anatomy). The fee is £15 15s., and examinations are held quarterly. Candidates for the Fellowship must be qualified medical men of not less than two years' standing and 24 years of age. Candidates approved at this examination are then eligible for election as Fellows. The Faculty can also elect three Fellows annually without previously submitting them to examination, provided they "have highly distinguished themselves in medical science or practice." They must be of not less than twenty years' standing and 45 years of age.

The fee for the Fellowship is £50. Further information can be obtained from Mr. David Willcox, Faculty Hall, 242, St. Vincent Street, Glasgow.

Ireland

MEDICAL REGISTRATION IN THE IRISH FREE STATE

The Medical Practitioners Act, 1927 (Irish Free State), provides for the establishment of a Medical Registration Council for the Irish Free State. The main functions of the Council are (1) to keep a register of medical practitioners who may desire to practise permanently or temporarily in the Irish Free State, and (2) to exercise disciplinary power with regard to all medical practitioners who are on the register and engaged in practice in the Irish Free State. The first schedule of the Act contains the agreement between Great Britain, the Irish Free State, and Northern Ireland. This agreement provides for the nomination of a member of the General Medical Council, formerly made for Ireland by His Majesty on the advice of the Privy Council, to be made henceforth by His Majesty in Council on the recommendation of the Governor of Northern Ireland. The nominations of members of the General Medical Council by universities and medical corporations in Ireland and the election of a member of the General Medical Council by registered medical practitioners in Ireland will be in all respects the same as heretofore. The constitution of the General Medical Council and of the several Branch Councils as formerly existing under the Medical Acts, and the powers of holding qualifying examinations and granting diplomas for the purpose of registration in the general *Register* formerly vested in certain universities and medical corporations in Ireland, are not affected by the establishment of the Irish Free State or of Northern Ireland, and for the purpose of the preparation and keeping of the general *Register* the General Medical Council and the Branch Council for Ireland have the same powers and jurisdictions under the Medical Acts as they exercised formerly. The agreement provides also that any person who is or shall be registered in the general *Register* shall be entitled on the payment of a prescribed fee to be registered in the *Irish Free State Register*, but this fee is not payable by any person who, on the date of the establishment of the *Irish Free State Medical Register*, is registered on the general *Register*. Then follow provisions with regard to the erasure from the *Register* of the name of a person on account of misconduct.

The *Irish Free State Medical Register* was established on May 26th, 1928, this being the date appointed by the Medical Registration Council. The *Register* on establishment contained the names of every medical practitioner who was registered in the general *Medical Register* immediately before May 26th, 1928, and who either was then resident in the Free State, according to his address as stated in the general *Register*, or was living outside the Free State and applied to the Council within one month before May 26th, 1928, to be registered. No fee for registration was charged in such cases.

For registration in the *Irish Free State Medical Register* subsequent to its establishment a fee is required, together with a prescribed form of application. A person is eligible for registration if he is at the time of application registered in the general *Medical Register*, or if he possesses the requisite qualifying diploma granted by colleges or bodies in the Free State as set out in the Act. Candidates for medical appointments made under the Appointments Commission must be registered in the *Irish Free State Medical Register*. Application for further information may be made to the Registrar, Medical Registration Council, Room 35, Upper Fitzwilliam Street, Dublin.

THE IRISH UNIVERSITIES

There are three universities in Ireland, each with a medical faculty. These are, in the Irish Free State, the University of Dublin (usually known as Trinity College, Dublin), and the National University of Ireland; and, in Northern Ireland, the Queen's University of Belfast.

UNIVERSITY OF DUBLIN: TRINITY COLLEGE

This university grants two degrees in medicine (M.B. and M.D.), two in surgery (B.Ch. and M.Ch.), two in midwifery (B.A.O. and M.A.O.), and two in public health. It also grants degrees in gynaecology and obstetrics, for which nine months' study is required, and in psychological medicine, for which twelve months' study is required. The degrees are granted to those who, having passed the professional examination, have also graduated in arts.

Professional Examinations

A candidate for the Final Examination for the M.B., B.Ch., and B.A.O. degrees must be a matriculated student of at least five years' standing. The examinations which students must pass are the Preliminary Scientific, the Intermediate Medical, and the Final. Before admission to any of these examinations students must have completed the courses of study in the subjects involved.

Preliminary Scientific. This covers (a) chemistry, (b) physics, (c) botany and zoology. The three divisions may be taken together or at different times.

Intermediate Medical.—This is divided into two parts: (a) anatomy, physiology, and histology; (b) applied anatomy and applied (clinical) physiology. The two parts may be taken separately or together.

Final Examination.—Part I: Pathology and bacteriology, materia medica and therapeutics. Part II: (a) Midwifery and gynaecology; (b) medicine, mental diseases, medical jurisprudence and hygiene; (c) surgery in all branches, including clinical ophthalmology. The three sections of Part II may be taken separately or together. In either case the full curriculum must have been completed, and the Final Examination cannot be completed before the end of the fifth year.

M.D.—The candidate must have passed all the qualifying examinations in medicine, surgery, and midwifery, and have taken, or have been qualified to take, the degree of B.A. three years previously. He must send in a thesis for approval. Subsequently the Regius Professor of Physic and an assessor will discuss with him questions connected with the thesis, and also examine him viva voce on other medical subjects of a more general nature.

M.Ch.—The candidate must be a B.Ch. of not less than three years' standing and must produce satisfactory evidence of having been engaged in practice for two years.

M.A.O.—The candidate must be a B.A.O. of not less than two years' standing and must produce satisfactory evidence of having been engaged for two years in the study of obstetric science. The examination is specially directed to obstetrics and practical gynaecology.

Further information regarding courses of instruction, etc., may be obtained from the Registrar of the School of Physic, Trinity College, Dublin.

QUEEN'S UNIVERSITY, BELFAST

The degrees granted by the Medical Faculty of this university are as follows: Bachelor of Medicine (M.B.), Bachelor of Surgery (B.Ch.), Bachelor of Obstetrics (B.A.O.), Doctor of Medicine (M.D.), Master of Surgery (M.Ch.), Master of Obstetrics (M.A.O.). The university also confers a diploma in public health and a diploma in psychological medicine. The first three degrees mentioned serve as a qualification for admission to the *Medical Register*, and are not granted separately. In addition to matriculating and passing his

professional examinations, a candidate for these degrees must have passed three of the regulation five years as a student at the Belfast School of Medicine. Degrees in dental surgery (B.D.S. and M.D.S.) are conferred by the university, and also a diploma in dental surgery (L.D.S.).

Professional Examinations

The examinations for the M.B., B.Ch., B.A.O. are four in number. The first deals with: (1) inorganic, organic, and practical chemistry, (2) experimental and practical physics, (3) botany and practical botany, (4) zoology and practical zoology. It is divided into two parts, of which botany and zoology form one. The Second Examination covers anatomy and physiology (both theoretical and practical), and may be taken at the end of the second year of the student's career. The Third Examination includes: (1) pathology and practical pathology, (2) materia medica, pharmacology, and therapeutics, (3) medical jurisprudence, and (4) hygiene. Candidates who have passed the Second Examination may present themselves for Part I of the Third (Nos. 1 and 2) at the close of the third year, and for Part II (Nos. 3 and 4) at the end of the winter session of the fourth year.

The Final Examination includes: (1) medicine, (2) surgery, (3) midwifery, (4) ophthalmology and otology. The student must pass in all subjects at once at the end of his fifth year. No certificate in regard to the study of the subjects of this examination will be valid unless the work was done subsequent to passing in all the subjects of the Second Examination.

The Higher Degrees

Candidates for the degree of Doctor of Medicine must be graduates in medicine of at least three years' standing, unless they hold also a degree of the university in arts or science, in which case a standing of two academic years will suffice. Moreover, candidates must be able to show that the interval has been passed in the pursuit of such courses of study or practical work as may be prescribed. The degree may be conferred either (a) after a formal examination, or (b) in recognition of the merits of a thesis or of some piece of original study or research carried out by the candidate, followed by an oral or other examination in its subject. When an ordinary examination is imposed it will include (1) a written paper on the principles and practice of medicine, (2) a commentary on a selected clinical case, (3) a clinical and viva voce examination, and (4) a written paper and clinical or practical and viva voce examination on a subject chosen from the following list: (a) human anatomy, including embryology; (b) physiology, (c) pathology, (d) pharmacology and therapeutics, (e) sanitary science and public health, (f) forensic medicine and toxicology, (g) mental diseases, (h) infant hygiene and diseases of children, (i) midwifery and infant hygiene. The regulations for the degrees of M.Ch. and M.A.O. are of the same general nature.

NATIONAL UNIVERSITY OF IRELAND

The National University of Ireland carries on most of its medical educational work through three constituent colleges—University College, Dublin; University College, Cork; and University College, Galway. Each of these provides a full medical curriculum, and all candidates for the medical degrees of the university must pass three of their five years of study at one or other of them. These years do not count except after matriculation in the Medical Faculty. The candidates at each constituent college are examined by the university, and a common standard of education is secured by all courses of instruction and the regulations concerning them having to be approved by the Senate, after considering report thereon from the General Board of Studies of the university. In addition to the ordinary degrees in Medicine and Surgery, the university grants those of Bachelor and Master of Obstetrics, Bachelor and Doctor of Science in Public

Health, and Bachelor and Master in Dental Surgery, as well as Diplomas in Public Health and in Psychological Medicine.

Application for other information may be made to the Registrar, National University of Ireland, 49, Merrion Square, Dublin, C.17.

THE IRISH CORPORATIONS

There are, in the Irish Free State, three licensing bodies other than the Medical Faculties of the universities; and in Dublin, just as in London, there is a Royal College of Physicians of Ireland, a Royal College of Surgeons in Ireland, and an Apothecaries' Hall. In Dublin, as in London and in Edinburgh, the two Colleges have formed an examining Conjoint Board, which is responsible for the recommendation of candidates to the two bodies for their respective licences. The Apothecaries' Hall of Ireland, like the Apothecaries' Society of London, gives its licence separately.

THE CONJOINT BOARD IN IRELAND

This body requires of candidates either the passage of its own preliminary examination in the subject of general education or proof that the candidate has passed one of the tests accepted by the General Medical Council as well as passing in the pre-registration examinations in chemistry and physics and biology.

Professional Examinations

There are three professional examinations, the first of which cannot be passed earlier than the end of the second winter session, nor the final before the conclusion of full five years of medical study. Before being admitted to any of them the candidate must show that he has studied the different subjects in practice and theory for the requisite periods, certificates to this effect being accepted from the authorities of most of the recognized medical schools at home and abroad. The First Examination deals with Part I—(a) biology, (b) applied chemistry and physics. Part II—anatomy, including embryology; physiology, including physiological chemistry and histology. The Second Examination deals with (a) pathology, including morbid anatomy, clinical pathology, and bacteriology; (b) materia medica, pharmacy, and therapeutics; (c) forensic medicine, hygiene, and public health; (d) ophthalmology and aural surgery; and may be taken separately.

Final Examination.—This is divided into three divisions, which cannot be completed until at least five years have passed in medical studies other than those for the pre-registration examinations, and five years at least since the beginning of the curriculum. The divisions are: (a) medicine, including fevers, mental diseases, and diseases of children; (b) surgery, including operative surgery; (c) midwifery, including diseases of women and newborn children, and the theory and practice of vaccination.

Fees.—Preliminary Examination—2s. Re-examination, £2 2s. P. £3 3s. Re-examination in C. £1 1s. First Professional Examination—Part I, £17 17s.; Part II, £10 10s.; Second, £9 9s.; Final, £6 6s. Re-examination fee is £2 2s. for each division.

Diploma in Psychological Medicine

There are two examinations in connexion with this diploma: Part I consists of (a) anatomy and physiology of the nervous system, (b) psychology. Part II—(a) neurology, including clinical and pathological neurology; (b) psychiatry, or psychological medicine, including its legal relationships. Fees, £6 6s. for each part.

Further information can be obtained from Mr. Alfred Miller, Secretary of the Committee of Management, Royal College of Surgeons, St. Stephen's Green, Dublin.

Royal College of Physicians of Ireland and Royal College of Surgeons in Ireland

The Diploma in Public Health

Every candidate for the Diploma in Public Health must observe the following rules:

1. Not less than two years shall elapse between the attainment by a candidate of a registrable qualification in medicine, surgery, and midwifery and his admission to the final examination for a diploma or degree in sanitary science, public health, or State medicine. (The purpose of Rule 1 is to provide opportunity for candidates while passing from the state of pupilage to that of responsible practice, to give mature consideration to the obligations and duties involved in the work of the Public Health Service, and to acquire direct experience of medical work in a responsible capacity, in general medical practice, in hospital or laboratory appointments, or in any special branch of clinical work or study related to State medicine.)

2. The curriculum for a diploma or degree in sanitary science, public health, or State medicine shall extend over a period of not less than twelve calendar months (or an academic year of whole time study covering a period of not less than nine calendar months) subsequent to the attainment of a registrable qualification.

3. Every candidate shall produce evidence of having attended, during not less than 280 hours, at an institution approved by the licensing body granting the diploma or degree practical instruction in: (a) bacteriology and parasitology (including immunology, serology, medical entomology, etc.), especially in their relation to diseases of man, and to those diseases of the lower animals which are transmissible to man; (b) chemistry, physics, radiology, and electrolgy in relation to public health; (c) physiology and biochemistry in their application to nutrition and hygiene; (d) meteorology and climatology in relation to public health.

4. Every candidate shall produce evidence of having received, during not less than 120 hours, at an institution approved by the licensing body granting the diploma or degree, instruction in: (a) the principles of public health and sanitation; (b) epidemiology and vital statistics; (c) sanitary law and administration (including public medical services); (d) sanitary construction (including licensing body granting the diploma or degree practical instruction for three months on the clinical practice of a recognized hospital for infectious diseases, and has received therein instruction in the methods of administration. At least twenty-four daily attendances of not less than two hours each shall be required.

5. Every candidate shall produce evidence that he has, during a period of not less than six months, been engaged in acquiring a practical knowledge of the duties, routine and special, of public health administration under the supervision of a medical officer of health, who shall certify that the candidate has received, from this officer or other competent medical officer during not less than three hours on each of sixty working days practical instruction in these duties, and also those relating to: (a) maternity and child welfare service; (b) health service for children of school age; (c) venereal diseases service; (d) tuberculosis service; (e) industrial hygiene; (f) inspection and control of food, including meat and milk. (Instruction in (a) to (f) should include attendance at the centres, clinics, institutions, and premises concerned.) Certificates of having received the prescribed instruction in public health administration must be given by a medical officer of health who devotes his whole time to public health work; or by the M.O.H. of a sanitary area having a population of not less than 50,000; or in Ireland the medical superintendent officer of health of a county or county borough having a population of not less than 50,000.

6. The examination for the diploma or degree shall be divided into two parts, Part I and Part II, each of which shall extend over not less than two days, and shall be conducted by examiners specially qualified. A candidate must pass in all the subjects of Part I before being admitted to examination for Part II. In Part I, and also in Part II, a candidate must pass in all the specified subjects at one time.

7. The examination for Part I shall be practical, written, and oral, and shall include the subjects referred to in Rule 3. Candidates may not be admitted to examination for Part I until after they have completed the prescribed courses of instruction in the subjects thereof.

8. The examination for Part II shall include the subjects referred to in Rules 4, 5, and 6. The examination shall be written and oral, and shall include practical examinations in infectious diseases; food inspection; inspection of premises—dwellings, factories, workshops, schools, etc. Candidates may not be admitted to examination for Part II until after they have completed the prescribed courses of instruction in the subjects thereof. No candidate shall be admitted to Part II of the examination for a registrable diploma or degree in public health until after the lapse of not less than two years from the date of his obtaining a registrable qualification in medicine, surgery, and midwifery, which qualification must be registered in the *Medical Register* before admission to Part II.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

Those whose names already appear on the *Medical Register* can obtain the separate Licence in Medicine of this College and its Licence in Midwifery. In either case an examination has to be passed in the subjects indicated, questions on midwifery, hygiene, and jurisprudence being included

in the examination for the Licence in Medicine. For the Licence in Midwifery practitioners of over five years' standing are exempted from examination by printed questions. The other grades of the College are Members and Fellows. The former are admitted after an examination which is open to graduates in medicine of recognized universities whose names are on the *Medical Register* of the United Kingdom or the Irish Free State, and Licentiate in medicine of the Royal Colleges of Physicians. The examination deals with the general subjects of medicine. Fellows are selected, by vote, from among the Members of the College.

Fees.—For the Licence in Medicine, 15 guineas; Special Examination, £21. For the Licence in Midwifery, 8 guineas; Special Examination, 16 guineas. For the Membership, 20 guineas to a Licentiate of the College, 35 guineas to others; £35, in addition to stamp duty, £25.

Information as to special examinations and other matters can be obtained from the Registrar, the Royal College of Physicians, Kildare Street, Dublin.

ROYAL COLLEGE OF SURGEONS IN IRELAND

This body, besides granting a Licence in Surgery, admits those possessed of registrable surgical qualifications to its Fellowship under certain conditions. Its Licence is usually granted conjointly with that of the Royal College of Physicians, but it is given separately to holders of a registrable qualification in medicine, provided the College is satisfied that adequate courses of study have been pursued, and provided its own provisional examination is passed. This examination is held on its behalf, by the Conjoint Board, and is identical with the ordinary surgical portion of the examinations imposed by that body.

The Fellowship.—Candidates for the Fellowship must pass two examinations, of which the first is in anatomy (including dissections), physiology, and histology; and the second in surgery (including surgical anatomy) and pathology. Both examinations are partly written, partly practical, and partly viva voce; while the Final Examination includes the performance of operations. All subjects of either examination must be passed at one time, and in neither can a candidate be admitted who has been rejected in any of its subjects by any other licensing body within three months. Candidates are not admitted to the Primary Examination except on evidence that they have already passed an examination in anatomy, physiology, and histology, held by some university or other body whose degrees or licences entitle the holder to admission to the *Medical Register*; if, however, the candidate's name is on the Colonial or Foreign List in the *Medical Register*, at the discretion of the Council. Candidates for the Final Examination must be over 25 years of age, produce a certificate of general good conduct signed by two or more Fellows of the College, and, if successful, must make a declaration before admission to the effect that they do not conduct dispensing practices, and will not do so as long as they are Fellows.

Fees.—Candidates for the Fellowship pay 5 guineas for each examination, the total of 10 guineas being reckoned as part of the fee payable on admission to the Fellowship. That fee is 25 guineas in the case of those who are already Licentiates, and 40 guineas in the case of others.

APOTHECARIES' HALL OF IRELAND

A diploma is granted by this Hall which entitles the holder to be registered as a practitioner of medicine, surgery, and midwifery, and confers also the privileges of an apothecary. Women candidates are eligible.

Fees.—First and Second Professional Examinations, £21; Final Examination, £21. Subjects of examination: First Professional, Anatomy and Physiology. Second Professional, Materia Medica and Pharmacy; Medical Jurisprudence and Hygiene; Pathology. Final Examination: Medicine, Surgery, and Midwifery. Candidates must enter for and pass at the one time in Anatomy and Physiology. They are at liberty to enter for the subjects of the Final Examination at separate

times, but the Final Examination cannot be completed until a period of three years has elapsed from the date of passing First Professional Examination.

Application for other information should be made to the Registrar, 95, Merrion Square, Dublin.

Medical Schools and Colleges

LONDON

Information as to the fees at each of the various metropolitan medical schools, and the scholarships, prizes, and junior appointments which they offer, will be found in the following pages. The courses they provide are fundamentally the same, and in all of them the arrangements made are such as to meet the requirements of students of every class—of those who are aiming at the diplomas of the English Conjoint Board or the Apothecaries' Society, not less than of those who have London or other university degrees in view. At all, too, special facilities are offered to students who have commenced their professional education at Oxford or Cambridge, and are seeking the medical degrees of those universities.

Charing Cross Hospital

Centenary Year

The School, which was formally opened in October, 1834, is this year celebrating its centenary by the issue of a public appeal for funds. One of the principal objects of the appeal is for the provision of a students' hostel. The inaugural ceremony will be held in the autumn, and details will be furnished to applicants.

Situated in the centre of London, Charing Cross Hospital Medical School is the most easily accessible of all the London schools. Instruction is given in all the subjects for the final examinations of the universities of London, Oxford, and Cambridge, the Conjoint Board, and other licensing bodies. In addition to the clinical appointments held by every student, courses of systematic lectures, demonstrations, and tutorial classes are held in all subjects of the curriculum. In the School there are departments devoted to bacteriology, clinical pathology, biochemistry, materia medica, public health, operative surgery, as well as laboratories for research. By reason of the abundance and variety of the material available for investigation, the Institute of Pathology, with its whole-time staff of scientific workers and its completely equipped laboratories, offers peculiar advantages to students in this branch of medicine. The Library has ample accommodation, and contains nearly 4,000 volumes, including modern textbooks and contemporary reviews. The Pathological Museum is organized in two sections: one devoted to specimens illustrating general pathological conditions; the other consisting of the Lockyer Collection, the finest collection of gynaecological and obstetrical specimens in the country.

The hospital contains 300 beds. The opening of the new Nurses' Home at Hampstead has released in the hospital considerable accommodation which is shortly to be converted into wards for paying patients, thereby increasing the number of beds to about 360. There are special departments for diseases of ear, nose and throat, the eye, the skin, for children, for mental disorders, for orthopaedic surgery and massage, for x-ray, electrical and light treatment, for dental surgery, and for tuberculous and diabetic cases. A number of beds are set apart for diseases peculiar to women and for midwifery cases, and the hospital serves an extensive and thickly populated district in gynaecological and obstetric work. The out-patient department dealt with 30,196 new cases last year, with 135,703 attendances. In-patients numbered 5,244.

The Students' Club provides for the athletic, recreational, and social life of the students by means of an 8-acre sports ground, with facilities for football, cricket, hockey, and tennis, by common rooms, restaurant, etc.,

and by sections of the club designed for a particular purpose, such as the debating society and the dramatic society.

Appointments.—The number of resident appointments as compared with the number of students in the School is exceptionally large, and students of reasonable ability and industry can usually be certain of obtaining one or more. The resident appointments to which election is made every six months number 14 (28 every year). During the time an appointment is held the officer receives a salary, varying with the post from £50 to £200 p.a., and is provided with free board and accommodation in the Residency of the hospital. In addition to the foregoing, two non-resident officers and a number of clinical assistants are appointed annually. **Higher Appointments.**—Annual election is made to the posts of resident medical officer (£400), resident casualty officer (£200), medical registrar (£150), surgical registrars (two, £150 each), obstetric registrar (£100), and registrar to the ear, nose, and throat departments (£100). The holders of these posts are eligible for election for a second year. Every student during the course of his clinical studies serves the offices of medical clerk, surgical dresser, and clerk and dresser to all the special departments.

Scholarships.—The following are offered annually: (a) For students commencing medical studies, two scholarships, each of the value of £50. (b) For students commencing clinical studies, two University Scholarships, each of the value of £120, in pathology; one University Scholarship, value £120; and one Open Scholarship, value £75, in anatomy and physiology. An "Epsom College" Scholarship (£100) is awarded periodically on the nomination of the Head Master, and a "Cranleigh" Scholarship on similar conditions. In addition there are a number of exhibitions.

Prizes.—(1) The Llewellyn Prize, £25, for highest distinction throughout final course of studies. (2) Williams Travers Prize, £15, midwifery and gynaecology. (3) Pereira Prize, £4 4s., clinical commentary. (4) T. H. Green Prize, £5 5s., clinical commentary. (5) Clinical Surgery Prize, £3 3s. (6) Clinical Medicine Prize, £3 3s. (7) John H. Morgan Prize, £10. (8) Steadman Prize in Pathology. (9) The Governors Clinical Gold Medal. (10) Class Prizes of £2 2s. each in Pathology and Bacteriology; Hygiene and Public Health; Ophthalmology, Oto-laryngology; Psychological Medicine; Midwifery; Practical Midwifery; Gynaecology, and Pharmacology and Therapeutics.

Fees.—The fees are as follows: Entrance for the whole course including Primary and Intermediate £16 16s.; for Final studies only £10 10s.; Annual, 38 guineas.

Further information may be obtained on application to Eric A. Crook, M.Ch., F.R.C.S., Dean of the Medical School, Charing Cross Hospital, London, W.C.2.

Guy's Hospital

The hospital contains 649 beds in constant occupation. Twenty-five beds are set apart for diseases of the eye, and 42 for the most urgent and interesting medical cases, which form the subjects of the weekly clinical lectures. There are special wards for the reception of cases of diseases of women and for cases of difficult labour. Beds are also allotted to the throat and ear departments, the departments of orthopaedics, neurology, and dermatology, the department for the treatment of diseases of the genito-urinary system, and the children's department; there are also some special beds for the treatment of syphilis.

The residential college fronts the east gate of the hospital, providing accommodation for resident students. This contains a dining hall, reading rooms, a library of general literature, and a gymnasium for the use of the residents and of the members of the Clubs Union. The athletic ground at Honor Oak Park is reached from the hospital in fifteen minutes. The Gordon Museum of Pathology, the Wills Library, the departments of chemistry, physics, pathology, and pharmacology, and the school buildings in general, afford opportunities for a liberal education and for research, and provide the full curriculum for all medical degrees and diplomas. The departments of anatomy, physics, and biology have been reconstructed and equipped on the most modern lines, and provide ample accommodation for teaching and research. Special classes are held for the First and Second Examinations for medical degrees of the University of London, for the pre-medical examination, and for the First and Final F.R.C.S. Eng. Examinations. Special teaching is provided to meet the requirements of the Universities

of London, Oxford, and Cambridge in general pathology and pharmacology.

Appointments.—All appointments are made according to the merits of the candidates, as determined by a committee of the medical staff. Sixteen out-patient officers, eight house-physicians, twenty assistant house-surgeons, eight house-surgeons, two ophthalmic house-surgeons, two genito-urinary house-surgeons, two house-physicians (children's department), two house-physicians (dermatological and neurological), and nine resident obstetric assistants are appointed annually. The house-physicians and house-surgeons, obstetric residents, ophthalmic house-surgeons, and genito-urinary house-surgeons hold office for six months each, and receive free board and lodging in the college. Every student is provided with rooms and commons in the hospital during the period of his "take in" as senior dresser. In addition to the clerkships and dresser-ships in the medical and surgical wards, students are appointed to the posts of clinical assistant dresser, or clerk in the special departments of ophthalmology, laryngology, gynaecology, diseases of children, diseases of the nervous system, dermatology, otology, actinotherapeutics, anaesthetics, dentistry, orthopaedics, vaccine, tuberculosis, fractures, and genito-urinary and venereal disease; clinical assistantships in the various special departments are open to post-graduates.

Scholarships, Prizes, etc.—The following scholarships in Arts and Science are awarded. A. Open Junior Scholarships: (1) An Arts Scholarship of the value of £100; (2) a Science Scholarship of the value of £100; these are awarded annually in April. (3) A War Memorial Scholarship of the value of £200, awarded alternately in Arts and Science. This scholarship is open every other year; the next award will be made in April, 1936 (in Arts). B. Confined Scholarship in Science. A junior Science Scholarship of the value of £100 is offered for competition annually in April to candidates who have attended the preliminary science classes at this school. Candidates for these scholarships (male students only) must be under 20 years of age on August 1st of the year of the competition. C. University Entrance Scholarships: (1) A War Memorial Scholarship, entitling the holder to free medical education for three years; (2) an exhibition of the value of £60; both of these are awarded annually in June or July. Candidates will be examined in two of the following subjects at their option: (1) anatomy and embryology; (2) physiology; (3) pathology, including bacteriology; (4) biochemistry. The examination is held in common with the Medical School of St. Thomas's Hospital and the Medical College of St. Bartholomew's Hospital. Full particulars as to the scholarships may be obtained from the Dean of the Medical School. Junior prizes for general proficiency, £20, £15, £10; Hilton Prize for dissection, £5; Michael Harris Prize for anatomy, £10; Sands-Cox Scholarship for physiology, £15 for three years; Wooldridge Memorial Prize for physiology, £10; Beane Prize for pathology, £34; Treasurer's Medal and Prize in medicine, Treasurer's Medal and Prize in surgery, and the Golding-Bird Gold Medal and Scholarship for bacteriology (£20) are awarded annually after competitive examination. The Gull Studentship in pathology, of the value of £250 per annum, the Beane Scholarship in materia medica, of the value of about £70, and the Anderson Demonstratorship in clinical chemistry, value £175 per annum, are awarded without examination to enable research to be carried on in these subjects. An Arthur Durham Travelling Scholarship of £100 is awarded triennially. The Griffiths Demonstratorship in Pathology, of the value of £320 per annum, and the Hilda and Ronald Poulton Fellowship, value £150 per annum, are awarded without examination.

An annual composition fee is paid by all students until a registrable qualification is obtained. Further information may be obtained from the Dean of the Medical School, Guy's Hospital, London Bridge, S.E.1.

King's College Hospital

The New Medical School at Denmark Hill, opened in July, 1933, contains the museum, research laboratory, research rooms, common rooms, lecture rooms, refectory, and two squash rackets courts. Provision is made for all the subjects of the medical curriculum. The hospital was opened in 1913, and is one of the most modern and best equipped in England. In the education at the hospital a special feature has always been the individual attention given to each student. The studies are co-ordinated under the direction of senior members of the honorary staff, assisted by medical, surgical, obstetric, and pathological tutors.

The Hall of Residence for members of the medical school is situated on Champion Hill. Both the Hall and the athletic ground are within ten minutes' walk of the school.

The Clubs and Societies Union combines athletics, music, and other societies connected with the school, and provides also a common room.

Appointments.—Thirty-one resident medical and surgical appointments are made during each year, as well as dressers and clerks in the wards, out-patient departments, post-mortem rooms, and special departments. Each of the special departments has clinical assistants. There are eight registrars and four tutors, all of whom receive salaries.

Scholarships, etc.—At entrance: Science Scholarship, £75. At commencement of Final Studies: Anatomy and Physiology Scholarship, £75; Pathology Scholarship, £75; two Raymond Gooch Scholarships, each £105; two Burney Yeo Scholarships, each £105 (for Oxford and Cambridge students); Seaman Scholarships, £50 a year up to five years; Epsom College Scholarship, £100; Senior Scholarship, £40; Todd Prize, Tanner Prize, Cheyne Prize, Legg Prize, Ware Prize, Fernier Prize in Neurology, Class Prizes and Medals.

Fees.—The composition fee is 93 guineas if paid in one sum. Entrance fee of 10 guineas.

Dental School.—This school was opened in October, 1923, and, in conjunction with King's College, provides complete courses for dental degrees and diplomas.

The calendar of the school can be obtained on application to the Dean, John A. Drake, M.D., F.R.C.P., D.P.H., or to the Secretary of the Medical School, S. C. Ranner, M.A., King's College Hospital, Denmark Hill, S.E.5.

The London Hospital

This hospital, with its medical college and dental school, is situated in the Mile End Road, E.1. The hospital contains 847 beds, which are in constant use. During 1933 14,515 patients passed through the wards and 106,099 out-patients received treatment. There are special departments for the treatment of diseases of the ear, nose, throat, eye, skin, and teeth, and in addition there are departments devoted to gynaecology and obstetrics, paediatrics, orthopaedics, brain surgery, venereal diseases, radiology, electro- and physico-therapeutics, radium, and vaccine therapy. The number of major operations which were performed amounted to 7,691.

The hospital presents, therefore, a large field for clinical instruction, and in its wards and out-patient and special departments exceptional opportunities are afforded for acquiring an extensive and practical experience of all phases of disease.

A clinical unit in medicine, under the charge of a whole-time director, assisted by an assistant director, two assistants, and two house-physicians, provides for the more elaborate methods of diagnosis and treatment, and takes a leading part in the initiation and co-ordination of medical research. To each medical and surgical firm throughout the hospital there is attached a first assistant, who is responsible for instructing the clerks or dressers of the firm in elementary medicine and surgery, and who assists the honorary members of the firm in the preparation of their demonstrations. In the department of cardiology there is a research scholar and a house-physician. In the department of obstetrics and gynaecology there is a first assistant and two resident accoucheurs. In the department for children's diseases there is a first assistant, one house-physician, and two clinical assistants; and in the department of neuro-surgery there is a house-surgeon. Special courses of lectures and demonstrations are arranged in medicine and surgery and in their ancillary subjects. Opportunities for research are provided under the supervision of the staff.

All the departments are modern and adapted for the teaching of all subjects in the various curricula. Special courses of instruction are held in preparation for the examinations of the University of London, for the Fellowship of the Royal College of Surgeons, and for the Membership of the Royal College of Physicians. Special entries can be made for the medical and surgical practice of the hospital. A resident hostel is provided for the holders of house appointments. A new students' hostel has been opened, and provides accommodation for upwards of fifty students. In the hostel there is a library, writing, common, and dining rooms, and two standard squash rackets courts. The athletic ground, of over thirteen

acres, is at Higham's Park, and is open to all members of the Club's Union.

Appointments.—The salaried appointments, open to past students of the hospital, are those of assistants to the medical unit; first assistants to the medical and surgical firms and to the department of obstetrics and gynaecology; medical, surgical, and obstetric tutors; clinical assistants in the medical, surgical, ophthalmic, aural, light and skin, orthopaedic, and electrical departments, and in the Institute of Pathology. There are appointed annually 4 resident accoucheurs, 16 resident house-physicians and 19 resident house-surgeons, 14 resident receiving-room officers, 8 resident emergency officers, 8 clinical assistants to the medical out-patient department, and 16 clinical assistants to the surgical out-patient department, also paid and unpaid clinical assistants in the various special departments. In addition, there are numerous assistantships, clerkships, and dresserships in the departments of medicine, surgery, gynaecology, and obstetrics.

Scholarships and Prizes.—The following is a list of scholarships and prizes:—At entrance: Price Scholarship in science, £100. Two open scholarships, each of the value of £100. A Scholarship open to students of Oxford and Cambridge Universities: £100, anatomy and physiology; Entrance Scholarship in science, £50; Epsom Scholarship, "free medical education." After entrance: Buxton Prize in anatomy and physiology, £40; Lethby Prizes in organic chemistry and chemical pathology, £25; Prize in clinical obstetrics and gynaecology, £20; Duckworth Nelson Prize in practical medicine and surgery, £10; Hutchinson Prize in clinical surgery, £60; Treves Prize in clinical surgery, £20; Sutton Prize in pathology, £20; Sir Andrew Clark Prize in clinical medicine and pathology, £14; T. A. M. Ross (prox. acc.) Prize in clinical medicine and pathology, £10 10s.; Anderson Prizes in elementary clinical medicine, £20; Dressers' Prizes, £20; Practical Anatomy Prizes, £10; Arnold-Thompson Prize in medical and surgical diseases of children, £15; Liddle Prize, £120; Francis Farmer Entrance Scholarship in biology, chemistry and physics, £25; Harold Fink Prize in dental surgery, £8 8s. The "London" Prize in dental prosthesis, £6 6s. Six class examination prizes of the value of £3 3s. to £5 5s. are offered for competition at the end of the courses of lectures in the dental curricula. Funds to the value of over £113,000 permit of financial assistance being given to students and graduates engaged in medical research.

Fees.—Entrance fee, 20 or 15 guineas, according to examinations passed; annual fee, 40 guineas.

Full information may be obtained from the Dean at the London Hospital Medical College, Mile End, E.1.

The Middlesex Hospital

The school and hospital are in Mortimer Street, W.1, close to Oxford Circus, Goodge Street, and Great Portland Street stations. There are a gymnasium, squash rackets court, common rooms, and restaurant within the hospital precincts, and an athletic ground within easy reach. The hospital contains 534 beds, including a wing containing 90 beds for patients suffering from cancer. There are special wards for maternity and gynaecological cases, for neurological cases, for cases of venereal disease, and for diseases of children and of the skin and eye, and a newly built west wing and residents' house.

The medical school, which includes the Bland-Sutton Institute of Pathology, the S. A. Courtlaud Institute of Biochemistry, the Barnato-Joel Laboratories, and the Ferens Institute of Otology, is completely equipped for teaching the entire medical curriculum, including the pre-medical subjects, chemistry, physics, and biology. The Bland-Sutton Institute, under the direction of the Professor of Pathology, contains large pathological and public health laboratories, and smaller rooms for original investigation, as well as a pathological and anatomical museum. Bacteriological and microscopical examinations of material from the wards, operating theatres, and out-patient departments are carried out in the laboratories, and senior students are eligible for clerkships in connexion with this work. Junior assistants in the pathological and bacteriological laboratories are elected annually from recently qualified students. Every facility is given for original research. The Biochemical Institute is under the charge of the Professor of Biochemistry, and contains teaching and research laboratories in addition to those devoted to the routine chemical pathological work of the hospital. The Barnato-Joel Laboratories offer unrivalled

opportunities for the study of cancer in both its clinical and its pathological aspects.

Appointments.—Thirty-three resident appointments are open annually for competition among students of the hospital. The officers reside and board in the residential college free of expense. Two casualty medical and two casualty surgical officers, and four resident officers to the special departments, are appointed annually. Eight house-surgeons are appointed every year at intervals, after examination; eight house-physicians are also appointed annually at similar intervals. An obstetric and gynaecological house-surgeon is appointed every six months. One senior and two junior resident assistant anaesthetists are appointed annually. A dental house-surgeon is appointed every eight months. Nine registrars, each at a salary of £300 per annum, are appointed annually. In the out-patient departments and wards the appointments are: clerk and dresser to the physicians and surgeons to out-patients; clerk in the departments for diseases of the skin and nervous diseases; dressers to the department for diseases of women, to the ophthalmic surgeon, to the throat and ear department, to the orthopaedic department, and to the dental surgeon. Extern midwifery clerks and post-mortem clerks are also appointed; every student secures six months' experience in midwifery and gynaecology without leaving London. The appointments are so arranged that every student may, during his course, hold all the out-patient and in-patient clerkships and dresserships. Non-resident qualified clinical assistants are appointed in the medical, surgical, skin, neurological, ophthalmic, throat and ear, odontological, children's, and electro-therapeutic out-patient departments.

Scholarships.—There are two Entrance Scholarships, value £100 each. Two annual Entrance Scholarships, of the value of £90 and £60 respectively, are open to students of the Universities of Oxford and Cambridge who have completed the curriculum for, or passed the examinations in, anatomy and physiology. Students joining the school in the previous April are eligible. The Freer Lucas Scholarship is annually awarded on the nomination of the Head Master to a pupil of Epsom College who has passed the first examination for medical degrees (Preliminary Scientific Examination). There is also a scholarship, awarded annually to students from New Zealand, which affords the holder the clinical advantages of the hospital for one year. In addition to the Entrance Scholarships, there are numerous other valuable scholarships, prizes, and exhibitions open to students of the hospital, including the Broderip Scholarships, value £60 and £40; Lyell Gold Medal and Scholarship, value £55 5s.; Freeman Scholarship, value £30; John Murray Gold Medal and Scholarship, value £25; Hetley Clinical Prize, value £25; Leopold Hudson Prize, value 11 guineas; and the Second Year's Exhibition, value 10 guineas.

The rebuilding of the hospital is being completed without the loss of a single bed, or any disorganization of its clinics.

Fees.—(a) Entrance fee, 25 guineas, payable on joining the medical school; Pre-medical students: For one year or less, £21. (b) Students who have completed the Preliminary Science course: Five annual fees of £45. The annual fee for further attendance at the medical school, if a registrable qualification has not been obtained, is £23. (c) Oxford and Cambridge and other students who have completed the Intermediate course: entrance fee, 15 guineas; three annual fees of £45; further annual fees as above. These fees are inclusive and cover the cost of instruction in vaccination, fevers, etc., and also the subscription to the amalgamated clubs and hospital journal.

Further information may be obtained from the Dean or the School Secretary.

St. Bartholomew's Hospital

This institution fills one side of Smithfield and Giltspur Street, covering the greater part of a large island of ground separated practically from all other buildings; it is on the edge of the City, and easily reached from all parts of London. The hospital contains 762 beds. Extensive buildings, opened in July, 1907, occupy part of the ground acquired from the old Bluecoat School, and these materially enhance the attractions of the hospital as a place of medical study. The medical school buildings, including the library, the museum, and the chemical, biological, and anatomical departments, have now at their side a very large building, which includes club rooms for the Students' Union, a writing room, luncheon and dining halls, new quarters for the resident staff, and an out-patient department and accommodation for special departments of such large size as to be unsurpassed by any

hospital in the kingdom. During the year 1909 a second block of new buildings was completed. These form the pathological department, and include, in addition to an extensive post-mortem room, large and well-equipped laboratories for clinical pathology, pathological histology, bacteriology, and chemical pathology, altogether forming the most complete pathological department in the country. A further large block in Giltspur Street was acquired in 1923, and has been equipped by the construction of new lecture theatres and extensive laboratories for physics, chemical physiology, experimental physiology, histology, and pharmacology. The new block of surgical wards and five operation theatres (one attached to each surgical unit), with accommodation for 250 patients, was opened in June, 1930. One of the old blocks previously used for surgical cases has been reconverted for the housing of an enlarged gynaecological and obstetrical unit, with separate operation theatres attached. The Students' Union owns grounds of some ten acres in extent for recreative purposes at Winchmore Hill, which is easily accessible from the hospital.

The Medical College has recently purchased the site and buildings in Charterhouse Square (five minutes' walk from the hospital), formerly occupied by the Merchant Taylors' School, and the whole of the pre-clinical departments will shortly be established there. Various athletic amenities are also available on this new site.

Special classes are held for students preparing for the Preliminary Scientific and other examinations, for the M.B., M.D. of the Universities of Oxford, Cambridge, and London, and for the higher surgical degrees at the same universities, including the M.Ch.Oxon., M.Chir.Cantab., M.S.Lond., and F.R.C.S.Eng.

Clinical Units.—Special clinical units have been established in medicine and surgery, each under the charge of a professor and director, who devotes the whole of his time to the purpose of hospital practice, teaching, and research. In each unit there are an assistant director and four assistants, for whom special laboratory accommodation has been provided by a gift from the Sir William Dunn Trustees. The appointments of clerks and dressers in these departments are open to all students, and arrangements are made for all students to study in these units during a part of their clinical course.

Appointments.—Clinical clerks to the physicians and to the physician-accoucheur, and dressers to the surgeons and in the casualty department, are chosen from the students; clerks and dressers are also selected from the students to attend in the out-patient rooms, in the special departments (ophthalmic, orthopaedic, gynaecological, children's, laryngological, aural, dermatological, venereal, electrical, and dental), and in the post-mortem room. Chief assistants and clinical assistants are selected from qualified men appointed yearly to help in the general medical, surgical, and in special departments. Ten house-physicians and ten house-surgeons are appointed annually. During their first six months of office they act as "junior" house-physicians and house-surgeons, and receive a salary of £80 a year. During their second six months they become "senior" house-physicians and house-surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant, an ophthalmic house-surgeon, a house-surgeon to the skin and venereal department, and a house-surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Three resident administrators of anaesthetics are appointed—the senior for one year at a salary of £150, and two juniors for six months with a salary at the rate of £80 per annum—and all are provided with board and rooms. An extra midwifery assistant is appointed every three months, and receives a salary of £80 a year.

Scholarships.—Five Entrance Scholarships and Exhibitions are annually awarded after examinations held in July, and one (the Shuter Scholarship) after examinations held in June. The subjects of examination and conditions of eligibility for these scholarships are: (1) and (2) one scholarship, entitling the holder to free undergraduate medical education for a period of three years, and one exhibition, value £60, in any two of the following subjects: human anatomy and embryology, physiology, pathology (including bacteriology), biochemistry. Candidates must have completed their examinations in anatomy and physiology in a British school or university outside the London Metropolitan area. (3) One scholarship, value £100, in the three following subjects: chemistry, physics, biology; limited to students under 21 years of age who have

not entered on the medical or surgical practice of any London medical school. (4) An entrance scholarship in arts, of the value of £100, in mathematics; Latin or Greek or French or German; a second language or chemistry or physics. (5) The Jeaffreson Exhibition in the same subjects as No. 4, of the value of £50. Candidates for Nos. 4 and 5 must be under 19 years of age. (6) Helen Cave Memorial Scholarship, awarded after open competition to sons of registered medical practitioners, value about £200, conditions obtainable from the Dean. (7) The Shuter Scholarship value £50, in anatomy and physiology, is confined to Cambridge graduates. The total value of the scholarships and prizes is over £1,700 annually.

Further information and a handbook can be obtained on application to the Dean of the Medical College, St. Bartholomew's Hospital, E.C.1.

St. George's Hospital

This school is at Hyde Park Corner, and is carried on in connexion with St. George's Hospital, an institution having a service of 436 beds, of which 100 are at the convalescent hospital at Wimbledon. It provides for the instruction of its students in the preliminary and intermediate subjects of the curriculum at the teaching centres of London University established at King's College and University College. The school at Hyde Park Corner is devoted entirely to the teaching of clinical subjects, great attention being paid by the members of the staff to individual teaching. A number of special courses are given, in which the requirements of university and all other examinations receive careful attention.

The St. George's Hospital Club consists of an amalgamation club, with smoking and luncheon rooms on the hospital premises, and other students' clubs, with an athletic ground at Wimbledon. Students have the advantage of a well-filled library of medical and scientific books. A register of accredited apartments and a list of medical men and others willing to receive St. George's men as boarders may be seen on application to the Dean.

Appointments.—Two house-physicians, two house-surgeons, and two casualty officers are appointed every three months. The house officers reside and board in the hospital free of expense. The casualty officers are non-resident, and receive salaries at the rate of £60 per annum. After the student has held a house appointment the following are, among others, open to him: assistant resident physician at £250 per annum; surgical chief assistant at £225 per annum; medical officer to the Atkinson Morley Convalescent Hospital at £300 per annum; medical registrarship at £200 per annum; medical officer to the biochemical department at £100 per annum; assistant curatorship of the museum, £100 per annum; obstetric assistantship, resident, at £100 per annum; the post of resident anaesthetist at £100 per annum.

Scholarships.—The following Entrance Scholarships and Exhibitions in anatomy and physiology and in general pathology are awarded in July to candidates who have passed the second M.B.London or corresponding examination; Senior William Brown Exhibition of the value of £120; Junior William Brown Exhibition of the value of £80; Anne Selina Fernee Scholarships (two) of the value of £80 each; Anne Selina Fernee Exhibitions (two) of the value of £60; Devitt-Pendlebury Scholarship of the value of £40; and Exhibitions, each of the value of £40 and up to four in number. Other prizes to the value of £200 are awarded annually to the students of the hospital.

Fees.—First year (First M.B. or pre-medical course), £36 15s.; second and third years, £42 each. For the course of clinical study, in the fourth and subsequent years, entrance fee, £10 10s.; annual composition fee, £42. No entrance fee is payable by St. George's students who have studied at King's College or University College.

Further information may be obtained from the Dean of the Medical School.

St. Mary's Hospital

St. Mary's is exceptional in its situation, for while it is adjacent to a large poor district in which it serves some 500,000 persons, one-tenth of whom (on an average) pass through the hospital annually for treatment of one kind or another, it is, nevertheless, so near to Kensington Gardens and one of the best residential districts of London

that it offers to the medical student the unusual possibility of living in close touch with his work, without a wearisome journey in an overcrowded train or tube. As a direct outcome of this, social life among students is closer than is possible where the members of a school live scattered in many parts of London and its suburbs.

The rebuilding of the Medical School and Institute of Pathology has just been finished. The new school occupies a site adjacent to the hospital, and provides departments for teaching the entire curriculum. There are also a students' club and restaurant, a large library, a gymnasium, a swimming bath, a squash rackets court, and an underground garage for fifty cars.

The principle underlying the clinical teaching is to encourage the student, under supervision, to carry out for himself the various methods of clinical investigation and treatment. This is secured by the provision of a very large number of appointments, and by developing the system of clinical clerkships and assistants. Large classes are avoided whenever possible, and the intimate association between staff and student has been reinforced by the institution of Clinical Units. St. Mary's is one of the three medical schools in London to enjoy the great advantages in teaching and research which these units confer. The clinical material is exceptional. A new block has recently been added containing two operating theatres and 60 beds. Owing to affiliation with adjacent hospitals, more than 1,000 beds are now available for teaching. There are lying-in beds at St. Mary's, with 450 confinements yearly, and in addition to the instruction thus obtained each student is sent (without further fee) to Queen Charlotte's Hospital for a fortnight as part of his training in midwifery.

Students especially interested in pathology and bacteriology have singular advantages at St. Mary's. The institute comprises seven special departments, the whole being under the personal direction of Sir Almroth Wright. Two Research Studentships of £200 each are awarded annually.

From three to five Entrance Scholarships, each representing free tuition, are awarded annually by nomination on the lines of the Rhodes Scholarships. Full particulars may be obtained from the School Secretary, St. Mary's Hospital, Paddington, W.2. Numerous appointments are open to newly qualified members of the medical school, including seventeen salaried posts with salaries varying up to £750 per annum.

A special post-graduate course is held at the beginning of October and is open to all general practitioners and other qualified men without fee.

The athletic ground (10 acres) at Wembley is within easy reach of the Medical School.

St. Thomas's Hospital

The Hospital and Medical School are situated along the Albert Embankment between Westminster and Lambeth Bridges. The buildings form one of the most striking architectural features of London, opposite the Houses of Parliament, with Lambeth Palace and the beautiful grounds adjoining immediately to the East.

The hospital consists of eight linked-up pavilions, the Medical School buildings being separated from the hospital by a quadrangle; they comprise a magnificent Department of Anatomy with its own lecture theatre, museums, and research laboratory, the School of Physiology, named after Sir Charles Sherrington, O.M., completely equipped for teaching and research, a newly rebuilt Department of Chemistry with special facilities for research; Physics and Biology Laboratories. The school buildings contain also the library and reading room, which overlook the river and contain approximately 8,000 volumes, also an excellent supply of periodical literature adapted to the needs of medical students and research workers. The Museum, named after Professor S. G. Shattock, is also situated in the School; it contains nearly 5,000 preparations, which illustrate all the morbid lesions of importance met with in the various organs of the body, many specimens of historical interest, and a type series to illustrate medical,

surgical, and gynaecological pathology. In the west wing of the School are the Pathological Institute and the Photographic Department. The post-mortem room was entirely rebuilt in 1932; it is a model of its kind, with a large demonstration amphitheatre, which is perfectly adapted for teaching purposes and for the intimate study of morbid pathology.

The complete curriculum is provided for; students can join the Medical School directly after passing the requisite examination in general education, and proceed at once to the study of the first M.B. pre-medical subjects, which are taught by experienced professors and lecturers with the assistance of full-time demonstrators. Private coaching facilities are available for those students who wish to supplement the routine classes which cover the entire syllabus laid down by the various examining boards. Most students, particularly those entering for the first M.B. pre-medical examination, enter in October, but the clinical studies are arranged in three-monthly periods, and students can join at any time of the year for the Intermediate and Clinical studies. Classes for the Primary F.R.C.S. are held before each examination; these classes are limited to students who have joined for the full curriculum, and are therefore small, permitting of intimate personal teaching. Revision classes in anatomy and physiology are arranged for students from Oxford and Cambridge. Classes in pharmacology and materia medica and pharmacy cover the requirements of all the examining bodies.

Clinical Studies.—The hospital contains 644 beds; in addition it has 30 beds (with teaching facilities over a further 150) at the Pyrford Orthopaedic Hospital, and 22 beds at the St. Thomas's Babies' Hostel in Lambeth. During 1933 the number of patients admitted into the hospital was 11,528; during the same period 98,780 out-patients were treated. In the Maternity Department 2,630 women attended; 420 were admitted into the special maternity ward and 660 were delivered in the district. Casualties to the number of 166,281 attendances were dealt with during the same period. In addition to the 696 beds actually controlled by the hospital, students have the advantage of a close liaison with Lambeth Hospital, where demonstrations of rare and advanced cases, such as are seldom seen in the wards of a general hospital, are arranged at regular and frequent intervals by the superintendent. The obstetric training of students has, during 1934, been supplemented by an arrangement with St. James's Hospital, Balham, whereby throughout the year two students at a time spend a fortnight in residence at St. James's Hospital, where they follow, and take part in, the maternity work of the hospital. Clinical teaching of medicine and surgery is carried out daily throughout the year in the wards and out-patient departments. From the day that a student enters on his clinical studies he comes into direct responsible contact with patients. Every student acts as clerk in the post-mortem room and in the pathological laboratories. The Medical Unit, through which every student passes for a period of three months, provides a very thorough grounding in clinical medicine and clinical biochemistry, the in-patient clerkship being afterwards completed under the aegis of a different medical firm. In addition to three months' dressing in the casualty department at the outset of his clinical studies, every student becomes, for six months, a dresser to one of the surgeons of the hospital; during this period he receives instruction in anaesthetics. Great stress is laid on the teaching of pathology, which proceeds *pari passu* with the clinical appointments held by the student throughout the curriculum. The special maternity ward in the hospital gives the student scope for elementary obstetric training before he takes his turn of duty on the district, where again he works under close supervision. All the special departments are available for the teaching of students; special attention is given to ante-natal instruction and the teaching of the diseases of children, a department through which every student passes. The laboratories and reading room in the units building are open day and night for those who wish to avail themselves of these facilities. A special Tuberculosis Department in the hospital forms a part of

the Lambeth scheme for the treatment of patients. The Venereal Disease Department is part of the L.C.C. scheme. The clinical material in the hospital is placed wholly at the disposal of undergraduate students; with the exception of a small class held twice yearly for the Final F.R.C.S. Examination, post-graduate clinical students are not accepted. Special tutorial classes in all subjects are held before all the final examinations of the universities and Conjoint Board.

St. Thomas's House—the Amalgamated Students Clubs' premises immediately opposite the hospital—was opened in 1927; it has all club amenities, with two squash rackets courts, a miniature rifle range, and ample garage accommodation. The hostel in the same building has accommodation, with all modern comforts, for 50 resident students. There is a hard tennis court in the Medical School quadrangle, and the beautiful sports ground at Chiswick provides for all field games.

Appointments.—Following qualification the following appointments are open to students: twenty-five clinical assistantships to the various special departments are appointed every three months. Eight resident casualty officers and anaesthetists, seven house-physicians, and nine house-surgeons are appointed every six months. Nine chief assistants (unpaid) to the special departments and nine non-resident registrars (medical, surgical, obstetric, and ophthalmic) at a salary of £250 to £300 a year hold appointments renewable yearly. A resident anaesthetist (salary £200), a resident assistant physician, and a resident assistant surgeon (salary £225 per annum) are appointed annually. Assistants in the medical and surgical units (salary £450 to £600) hold appointments with a maximum tenure of four years. Three assistants in the Department of Pathology hold appointments at a salary of £450 to £600 a year.

Scholarships and Prizes.—At this School there are the following Entrance Scholarships: Three in Natural Science, of the value of £150, £100, and £60 respectively; the University Scholarship of £100 in any two of the following: anatomy, physiology, pathology, chemistry, also the "Hector Mackenzie" University Exhibition of the value of £60. The value of all Entrance Scholarships is taken out in Tuition Fees. The money value and subjects of examination of the remainder are as follows: (a) William Tite Scholarship for second-year students £25; (b) and (c) Musgrove Scholarship or (alternatively) Peacock Scholarship each for third-year students and tenable for two years £35 each; (d) Mead Medal, medicine, pathology, and hygiene; (e) Wainwright Prize, medicine; (f) Toller Prize, medicine; (g) Cheselden Medal, surgery and anatomy; (h) Clutton Memorial Medal in Clinical Surgery, biennial; (i) Beaney Scholarship £50, biennially, surgery and surgical pathology; (j) Solly Medal and Prize, biennial reports of cases; (k) Sutton Sams Prize, biennial reports of cases; (l) Bristowe Medal, pathology and morbid anatomy; (m) Hadden Prize, pathology and morbid anatomy; (n) Grainger Testimonial Prize £31 10s., anatomy and physiology; (o) Louis Jenner Research Scholarship tenable for two years, £60 annually, pathology; Perkins Fellowship £40-£100, research; Myers Prize in Psychological Medicine 10 guineas.

University College Hospital

The school, which forms part of the corporation of University College Hospital, is in immediate proximity to the hospital in University Street, and opposite University College. It comprises departments of medicine, surgery, midwifery and gynaecology, pathology including morbid anatomy, chemical pathology, biochemistry and bacteriology, cardiography, forensic medicine, mental physiology and mental diseases, dental surgery, practical pharmacy, and other departments for the study of special diseases, such as those of the eye, skin, ear and throat, venereal diseases, and for instruction in anaesthetics, electro-therapeutics, and skiagraphy. The hospital and school have acquired the National Dental Hospital and College as their dental departments, thus providing every facility for the study of dental subjects. The Royal Ear Hospital has also been amalgamated as the Ear, Nose, and Throat Department, and a new hospital for in- and out-patients, close to University College Hospital. It contains 41 beds, including eight private wards for patients of limited means.

The school thus provides the final course of study for the degrees of the Universities of Oxford, Cambridge, London, Durham, and other British universities, and for the diplomas of the Royal Colleges of Physicians and Surgeons

in medicine and in dental surgery. Each department is also equipped for more advanced work, and provides facilities for research.

Clinical units in medicine, surgery, and obstetric medicine are now in operation. The whole-time directors of the units are concerned with the organization of the teaching generally, but the honorary staff is responsible for the largest share of the teaching in the wards and out-patient department of the hospital. The main hospital contains 414 beds.

The new buildings of the obstetric hospital of 85 beds (rendered possible by the Rockefeller benefaction), the new Residents' House (with accommodation for 33 residents and students), the extension of the Nurses' Home, and the new research laboratories for the Medical School, are now finished and in full occupation.

A Students' Hostel adjoins the Medical School. Large, airy, and handsomely furnished bed-sitting rooms, each fitted with hot and cold running water, are available.

Appointments.—The qualified appointments, in addition to a number of posts as house-physicians and house-surgeons and obstetric assistants, include the appointments of resident medical officer, medical registrars, surgical registrars, obstetric registrar, Harker Smith radium registrar, ophthalmic registrar, casualty medical officers, casualty surgical officers, assistants in ear, nose and throat, skin and venereal diseases departments, and house anaesthetists.

Scholarships.—The following scholarships and prizes are open to competition: Two Goldsmid Entrance Scholarships entitling the holder to the final course of medical study; one Goldsmid Entrance Exhibition entitling the holder to a reduction by £80 of the fees due for the full course of final medical study, open to candidates who are graduates in arts or science of a university of the British Empire; and a Filliter Entrance Scholarship in pathology, entitling the holder to a reduction by £52 10s. of the fees due for the full course of final medical study. The examination for these scholarships is in any two of the following subjects: anatomy, physiology, general pathology and biochemistry. The examination for 1935 will be held as follows: Monday, July 15th, 10 a.m. to 1 p.m., anatomy; 2 p.m. to 5 p.m., physiology. Tuesday, July 16th, 10 a.m. to 1 p.m., biochemistry; 2 p.m. to 5 p.m., general pathology. Candidates for the Filliter Exhibition need take pathology alone. Radcliffe Crocker Travelling Scholarship in dermatology for one year, value about £280; the Graham Scholarship in pathology of a sum not exceeding £400 per annum; Leslie Pearce Gould Research Scholarship in surgery for one year, value about £260; the Atkinson Morley Scholarship of £45 a year for three years, awarded after examination in the theory and practice of surgery; the Atchison Scholarship of £55 a year for two years for general proficiency in medical studies; the Magrath Clinical Scholarship, value about £160; Ferriere Scholarship, value £25; the Filliter Exhibition in pathology of £30; the Percival Alleryn Prize for the advancement of surgery by research, value about £110; the Graham Gold Medal for research work; four Fellows' Medals in clinical medicine; Liston Medals in clinical surgery; the Bruce Medal in pathology and surgery; two Tuke Medals in pathology; the Erichsen Prize for practical surgery; and the Roberts Prize in obstetrics and gynaecology.

Fees.—Inclusive fee to cover complete course for three years. Oxford: £40 per annum for three years. There are no extras, as these fees include courses of instruction in pharmacy, vaccination, and fevers, and life subscription to the Medical Society of Women's Medical Club.

Particulars of general and special courses can be obtained on application to the Dean of the Medical School, University College Hospital, University Street, W.C.1.

Westminster Hospital

The school, with its hospital situate in Broad Sanctuary, opposite Westminster Abbey, provides for the education of its students in the preliminary and intermediate subjects of the University of London at King's College, Strand, and University College. The rest of the work is done in the school buildings near the hospital. The number of in-patients averages 4,800 and out-patients upwards of 27,000 annually, and the hospital and school afford ample facilities for instruction in all branches of medicine and surgery. Every student must perform the duties of out-patient dresser for three months, and afterwards hold the office of in-patient dresser for three months. He is

also required to serve two terms of three months each as medical clinical clerk to the in-patient physician, and one term as gynaecological clinical clerk. Two pathological clerks are appointed every three months to assist in the post-mortem room. No student is eligible as an in-patient dresser or clinical clerk until he has completed his examination in anatomy and physiology. Clerks and dressers in the special departments of hospital practice are periodically appointed.

An annexe devoted to radium therapy and research, containing twenty-two beds, has recently been opened.

The athletic ground is situated at Tooting, and can be reached in twenty minutes from the hospital.

Appointments.—A medical and surgical registrar are appointed annually, each with a salary of £150, and an obstetric registrar with a salary of £50 plus £50 for tutorial fees. An assistant medical registrar and an assistant surgical registrar, salary £100 per annum each, are appointed for six months. A senior resident and casualty officer, salary £104 per annum and board, appointed for six months, may be extended for a further period of six months. A medical registrar to the children (Wander scholar), salary £250, is appointed for one year. Three house-physicians, three house-surgeons, three assistant house-physicians, three assistant house-surgeons, and a resident obstetric assistant are appointed after examination; and are provided with rooms, commons, and salary of £52 per annum, except the assistant house-physicians and the assistant house-surgeons, who are provided with commons only. The assistant house-physicians, after three months' service, become house-physicians for a further period of six months, and the assistant house-surgeons, after three months' service, become house-surgeons for a further period of six months. One house-anaesthetist is appointed for six months, non-resident, salary £100 per annum. Clinical assistants to the assistant physicians and assistant surgeons, and to the officers in charge of special departments, are appointed from among the qualified students.

Scholarships.—The following open scholarships are offered for competition during the year 1934-5. In the winter session two scholarships in anatomy and physiology, £75 each. In the spring two scholarships in anatomy and physiology, £75 each. A certain number of scholarships are allotted to universities of England, Wales, and the Colonies, and to public schools. These scholarships are awarded entirely on the nomination of the Principal of the university or school.

During the period of study the following prizes may be competed for: Sturges Prize in Clinical Medicine (Reports on Cases); Chadwick Clinical Surgery Prize (Reports on Cases); Chadwick Prize (Medicine and Surgery); Frederic Bird Medal and Prize; Abraham's Prize (Clinical Pathology); Hanbury Prize in Diseases of Children; Class Prize in Midwifery, Diseases of Women, Medicine, Pathology, Forensic Medicine, Bacteriology, Public Health, and Surgery.

Fees.—The annual composition fee is 40 guineas. An entrance fee is payable by all students—namely, primary and intermediate students, £10 10s.; students entering for the final subjects, £8 8s. These fees, which include subscriptions for membership of the Clubs Union, are subject to alteration from time to time as the School of Medicine may direct.

Further information and a prospectus can be obtained on application to the Dean at the Westminster Hospital Medical School, Caxton Street, Westminster, S.W.1.

London (Royal Free Hospital) School of Medicine for Women

The school is situated at 8, Hunter Street, Brunswick Square, W.C.1, close to the Royal Free Hospital. It is, like all the other London schools which have so far been mentioned, one of the constituent schools of the University of London. The laboratories are extensive and well lighted, and are fully equipped for the examination courses of the University of London and the Royal Colleges of Physicians and Surgeons. Research laboratories are attached to all departments. A large, well-equipped library, common room, Union Room, and refectory are provided for the use of students. Resident accommodation for 80 students is provided in students' chambers attached to the school.

The Royal Free Hospital, Gray's Inn Road, W.C.1, has 301 beds, all of which are available for clinical instruction. The obstetrical and gynaecological unit controls 68 beds. A large maternity district is served from the unit with a separate maternity hostel in the Essex Road, Islington. There are separate departments for diseases of the eye, ear

and skin, children and infant welfare, venereal diseases, orthopaedic surgery, massage, light, electrical and x-ray work, dentistry, and casualty. Students attend the practice of one of the fever hospitals of the London County Council and receive special instruction in lunacy at Horton Mental Hospital, Epsom; they are also admitted to the practice of a number of special hospitals, and hold clerkships and dresserships at the Elizabeth Garrett Anderson Hospital, the Cancer Hospital, Hospital for Sick Children, Great Ormond Street, the National Hospital for Nervous Diseases, the South London Hospital, the Central London Ophthalmic Hospital, and the Royal Ophthalmic Hospital. The work of the school includes preparation for the Primary Fellowship examination.

Appointments.—Qualified students of the school can obtain appointments as house-physicians and house-surgeons, obstetric assistants, surgical, gynaecological, and medical registrars, assistant pathologists, assistant anaesthetists, medical electrician, skiagrapher, and clinical assistants and demonstrators in various subjects.

Scholarships.—The Isabel Thorne and A. M. Bird Entrance Scholarships, value £30 a year for six years, the St. Dunstan's Medical Exhibition, value £60 a year for three years, which may be extended to five years, the Alfred Langton Scholarship of £50 a year for two years, the Flora Murray Bursary of £50, and the Mabel Sharman-Crawford Scholarship, value £20 a year for four years, are offered for competition in each year. The Sir Owen Roberts Memorial Scholarship of the value of £75 a year for four years; the Mrs. George M. Smith Scholarship of the value of £50 a year for three years, which may be extended to five years; the Dr. Margaret Todd Scholarship of the value of £37 10s. a year for four years; and the Sarah Holborn Scholarship of the value of £20 a year for three years, which may be extended to five years, are awarded in alternate years. The School Jubilee Bursary of £50 a year for three years is offered every third year. The Bostock Scholarship, value £90 a year for two or four years, is awarded by the Reid Trustees on the result of an examination held in May by the University of London every fourth year. The holder of the scholarship must enter the London School of Medicine for Women. The Lieutenant Edmund Lewis and Lieutenant Alan Lewis Memorial Scholarship, of the value of £25 a year for four years, is awarded every fourth year. The A. M. Bird Clinical Scholarship of £30 a year for three years. The John Byron Bursary of £20 a year for two years, the Julia Ann Hornblower Cock Prize of £60, the Helen Prideaux Prize of £60, the Mabel Webb and A. M. Bird Research Scholarship of £200 for one year, the Fanny Butler Scholarship of £16 a year for four years, the A. M. Bird Post-graduate Scholarship of £200 for one year, together with many other scholarships and prizes, are offered on sundry conditions. The Dr. Edith Pechey-Phipson Post-Graduate Scholarship of £100 is awarded annually. Altogether the school offers annually £1,950 in scholarships. Various missionary societies also offer scholarships on certain conditions, and assist women who wish to go to India and other countries as medical missionaries.

Fees.—Courses for the University of London degrees and the diplomas of the Conjoint Board in England, and other qualifications: £50 per annum throughout the course.

The Students' Union exists to promote corporate action of the students on matters of common interest, to promote and maintain athletic and other clubs, and to issue a school magazine. All students are required to become members of the Union.

Further information can be obtained from the Warden and Secretary.

King's College

The Medical Faculty at this College of the University of London gives instruction in the subjects of medical science for all the usual preliminary and intermediate examinations in medicine, surgery, and dentistry. Through the four associated hospitals students of the college have clinical facilities of over 1,000 beds, but they may also proceed to any other teaching hospital in London for final studies for the degrees of the University of London.

The Medical Faculty of the College provides a general university education in touch with other faculties, classes of which medical students are permitted to attend. There are many college societies, clubs, and functions in which students of all faculties have opportunity of meeting each other. The college has a large athletic ground at Mitcham, upon which there has recently been erected a new pavilion.

The first-year subjects are taught in the large departments of the Faculty of Science. Within the last few years there has been complete-remodelling of the second and third year medical departments at a cost of £70,000. This has comprised a new Department of Anatomy and reorganization, with considerable extension, of the Department of Physiology.

Scholarships.—The entrance scholarships are: (1) Two Warneford Scholarships, each £30 for four years; subjects—selected from mathematics, classics, divinity, and science. (2) One Sambrook Scholarship of £30 for three years; subjects of examination selected from mathematics, classics, and science. The holders of the preceding awards must proceed to King's College Hospital. (3) Worsley, £100, paid in five annual instalments. (4) Rabbeth Scholarships, value £30 and £15, in July, for the best student of the first-year. (5) Daniell Scholarship, £40, awarded on the results of the University Honours Examination. (6) The Layton and Berridge Studentships, each £150 and £100 per annum respectively, and (7) numerous prizes.

Full information as to admission, fees, and scholarships can be obtained from the Dean of the Faculty of Medical Science, King's College, Strand, W.C.2.

University College

This institution, one of the principal component parts of the University of London, possesses a Faculty of Medical Sciences whose work covers all the subjects included in the group commonly known as the preliminary medical sciences—namely, physics, chemistry, botany, and zoology; and also the intermediate medical sciences—namely, anatomy (including embryology and histology), physiology, biochemistry, and pharmacology. The anatomy building, provided by the munificent gift of the Rockefeller Foundation of New York, was opened on May 31st, 1923, by His Majesty the King. This building forms part of the block which includes physiology and pharmacology. A new building has recently been added for the department of zoology, for the endowment and equipment of which the Rockefeller Foundation has made another generous benefaction. Research work is undertaken in all the above-named departments. The College undertakes the education of students in all the subjects mentioned, leaving them free to complete their education in the strictly professional subjects—medicine, surgery, and the like—at any one of the recognized schools of advanced medical studies. The work is somewhat differently arranged, according to whether the student has in view the degrees of the University of London or the diplomas of the Royal Colleges. In either case the whole work to be done is divided into courses devised to meet the requirements of different examinations, and students can join the College for any of them. Women students are admitted to all courses on the same terms as men. The general arrangements for the benefit of students include membership of the Union Society or the Women's Union Society, with use of the College gymnasium and the athletic grounds. There is also a collegiate residence for about sixty-seven men students at Ealing and for one hundred and seventy-two women students in Malet Street.

Scholarships.—The scholarships and exhibitions obtainable include the Bucknill Scholarship, value 160 guineas, in chemistry, physics, botany, and zoology (the successful student must complete his work at University College Hospital Medical School)—the examination includes an English essay; two Entrance Exhibitions in the same subjects, each of the value of 55 guineas; a Faculty of Medical Sciences Entrance Scholarship, value £30 a year, for three years; the Bayliss-Starling Memorial Scholarship (physiology and/or biochemistry), £120; and the Ferriere Scholarship, £25, tenable for three years at University College Hospital Medical School.

Fees.—The fees for the courses covering the work of the First Examination for medical degrees of the University of London, and in both parts of the Second Examination, amount to 115 guineas. The fees for the courses covering the corresponding examinations held by the Conjoint Board in England also amount to 115 guineas. These fees do not cover tuition for more than a stated period.

A handbook specially relating to this faculty may be obtained on application to the Secretary of University College, London, Gower Street, W.C.1.

THE PROVINCES

There are in England and Wales, not counting London, ten medical schools, each supplying instruction in the full medical curriculum. Accounts of them here follow. In several cases information is appended about hospitals other than those directly connected with the school in question; such hospitals, officially and unofficially, play a part in the education which the students of the school receive, and in any case serve as places of additional or post-graduate study.

Oxford and Cambridge

At both Oxford and Cambridge there are medical schools which furnish unsurpassed opportunities for obtaining a good knowledge of the preliminary sciences and of anatomy, physiology, and pathology. The laboratories are excellently furnished, and the teaching staffs most distinguished. Both schools provide a full medical curriculum, and there is no essential reason why the student should not complete his career at either of them; but this is not commonly done, and is never, in the ordinary way, advised by the university medical authorities. The local hospitals—the Radcliffe Infirmary at Oxford and Addenbrooke's Hospital at Cambridge—though well equipped, are comparatively small. Students are therefore encouraged, as soon as they have completed the earlier examinations and taken a degree in arts, to join one of the London medical schools, and thus spend the time of their preparation for the final examinations in a city where the opportunities for gaining clinical knowledge are greater and more varied. A considerable proportion of Oxford and Cambridge medical students take the London Conjoint diplomas before graduating in medicine and surgery at their own university. The experience gained by holding resident hospital appointments is naturally of much advantage when sitting for the Final M.B. examination and when engaged in composing a thesis.

Birmingham

The school in this city is carried on by the Medical Faculty of the University of Birmingham, its students having an adequate number of good laboratories, classrooms, and other necessities devoted to their use by the university. The clinical work is done at the General and Queen's Hospitals, which are amalgamated for the purpose. Together they have upwards of 800 beds for medical, surgical, and special cases, with an array of special departments of all kinds, including one for lying-in women (about 13,000 in-patients and 90,000 out-patients). Clinical instruction is given in the wards and out-patient and special departments daily, and formal clinical lectures are delivered weekly throughout the session. Special tutorial classes are also held alike for the degrees of Birmingham and other universities, and for the diplomas of corporations.

Appointments.—The large number of appointments open to past or other students includes the following:—At the General Hospital: two surgical registrars, £100 (commencing) a year; one resident medical officer, salary £155 a year; one resident surgical officer, salary £180 a year; one assistant resident surgical officer, salary £100 a year; one resident pathologist, salary £70 a year; two visiting anaesthetists, salary £50 a year; two resident anaesthetists, salary £120 a year; four house-surgeons, office tenable for nine months, £70 a year; one house-surgeon to the gynaecological and one to the special departments, each tenable for six months, £70 a year; four house-physicians, post tenable for six months, £70 a year. At the Queen's Hospital: one resident medical registrar, salary £200 a year; two resident surgical officers, £100 a year, tenable for three years; three house-physicians, three house-surgeons, one obstetric and one ophthalmic house-surgeon, one ear, nose, and throat house-surgeon, and one house-physician for duty at the Nerve Hospital (associated with Queen's Hospital), tenable for six months, salary £70 a year, with board, lodging, and washing; one casualty house-surgeon,

tenable for three months, salary £70 a year, with board, lodging, and washing. At the City Public Assistance Institutions: five resident medical officers. At the Birmingham General and Branch Dispensaries: twelve resident surgeons. At the Birmingham Mental Hospitals: five assistant medical officers. At the City Fever Hospitals: three assistant medical officers. At the Children's Hospital: one resident surgical officer, one resident medical officer. At the Birmingham and Midland Eye Hospital: four resident surgeons. At the Orthopaedic and Spinal Hospital: two clinical assistants (non-resident). At the Ear and Throat Hospital: one house-surgeon, £70 a year; four clinical assistants (non-residents). Four non-resident appointments are in the gift of the Public Assistance Committee.

Scholarships.—There are numerous money and other awards for students of sufficient merit, among them being the following: Frank Fletcher and Catherine Fletcher Scholarships (not less than two per annum), tenable for five years, each of the annual value of £100, awarded on higher school certificate examination of the Joint Matriculation Board; the Walter Myers Travelling Studentship of £300, offered each alternate year for research work and tenable abroad; the Sands-Cox Scholarship of £42 (an entrance scholarship in the Faculty of Medicine, awarded on higher school certificate examination of the Joint Matriculation Board (July)); four Queen's Scholarships of £10 10s. each, awarded annually at the second (Part II), third, fourth, and final university examinations respectively; one or more Sydenham Scholarships, allotted on entrance to students who are the sons of deceased medical men; the Logleby Scholarships (two) of £10 for proficiency in midwifery and diseases of women; the Arthur Foxwell Memorial Gold Medal (clinical medicine); the Sampson Gamgee Memorial Medal for surgery (Final M.B.); the Russell Memorial Prize (for examination in nervous diseases, final year); the Priestley Smith Prize in ophthalmology, value about £6 (awarded in the final examination); and the Peter Thompson Prize in anatomy (value about £6) for students in their third university year; and the John Barritt Melson Memorial Gold Medal in Physiology for students in their third university year. There is also a scholarship of £46 17s. 6d. for students proceeding to a degree in dental surgery. University Clinical Board Prizes are awarded annually as follows: Senior Medical Prize, gold medal; Senior Surgical Prize, gold medal; Midwifery Prize, gold medal; Junior Medical Prize, silver medal; Junior Surgical Prize, silver medal.

Fees.—The composition fee for university classes is £106 5s. This covers all the work required for the degrees of Birmingham and some other universities, and for the ordinary qualifications of licensing corporations, but not the additional courses required for the Fellowship of the Royal College of Surgeons of England, the diploma and degrees of the university in State medicine, and some other special work. The total cost for the six years' curriculum, including hospital and examination fees, is £246 0s. 6d. (If first-year science subjects are excluded, £208 15s. 6d.)

Other information should be sought from the Registrar, or the Dean of the Faculty of Medicine, University, Edmund Street, Birmingham.

Bristol

The school is carried on by the Faculty of Medicine of the university, and provides full instruction for all its degrees and for the diploma in dental surgery.

Clinical Instruction.—The allied hospitals (Bristol Royal Infirmary and Bristol General Hospital) have between them more than 700 beds and extensive out-patient departments, special clinics for diseases of women and children, including ante-natal and post-natal work, also for eye, ear, nose and throat, and skin diseases, in addition to large and well-equipped departments for dental work and large outdoor maternity departments. The Bristol Royal Infirmary has now been selected by the National Radium Commission as a Radium Centre. At each of these institutions there are well-arranged pathological museums, post-mortem rooms, and laboratories for morbid anatomy. There are also laboratories for work in clinical pathology, bacteriology, and biochemistry, in which special instruction is given in these subjects. Departments are provided and well equipped for radiology, radiotherapy, actinotherapy, electrotherapy, and massage, with all forms of physiotherapy. The students of the school also attend the City and County Mental Hospital, the Ham Green Hospital for instruction in fevers and tuberculosis, the practice of the Royal Hospital for Sick Children and Women, containing 120 beds, and that of the Bristol Eye Hospital, with 40 beds. In addition, by the kind permission of the Health Committee of the

Bristol City Council, students may attend the clinical practice at Southmead Hospital, and may complete under certain conditions their practical work in obstetrics at that institution, which has 672 beds. The Orthopaedic Hospital at Winford and Stoke Park Colony for Mental Defectives are also available.

Appointments.—(1) Undergraduate: Medical clerkships, surgical dresserships, also ophthalmic, obstetric, pathological, dermatological, ear, nose, and throat clerkships, are tenable at the Bristol Royal Infirmary and the Bristol General Hospital. In these institutions the dressers reside in rotation free of charge. (2) Post-graduate: At the Bristol Royal Infirmary: four house-surgeons, one casualty house-surgeon, three house-physicians, one resident obstetric officer, one gynaecological and dermatological house-surgeon, one ear, nose, and throat house-surgeon, one assistant house-surgeon (who also acts in the ophthalmic department), one dental house-surgeon, and one unpaid assistant (usually a resident student) to the senior resident medical officer. All these appointments are for six months. Salary in each case at the rate of £60 per annum, with board, apartments, and laundry, except the casualty house-surgeon and the dental house-surgeon, who receive £80 per annum. In each case the salary is increased by £10 per annum if the officer is re-elected for another six months. From the resident medical officers a senior resident medical officer is appointed at a salary of £200 per annum. Clinical assistantships in all departments are open to senior qualified practitioners. At the Bristol General Hospital: senior resident medical officer, £200 per annum; casualty house-surgeon, £100 per annum; two house-physicians, £80 per annum; two house-surgeons, £80 per annum; resident obstetric officer, £80 per annum; house-surgeon to special departments, £80 per annum. All the £80 appointments carry a salary of £100 for residents who have previously held another of them; the dental house-surgeon (non-resident), £300 per annum. All these appointments are for six months, except that of senior resident medical officer, which is for two years. Clinical assistantships in the out-patient departments are also available.

Scholarships.—The following are among the scholarships and other awards open to students of the school: The Miriam Badock of the value of £120, and the H. H. Wills Science Scholarships, open to boys proceeding from Clifton College; the Harold Greenwood Memorial Scholarship of the value of £20, open to boys who have received instruction at State-provided schools in Clevedon (or elsewhere in Somerset) and subsequently at secondary schools in Somerset or Bristol; the Ashworth Hallett Scholarship, value £40, open to women only; two Martyn Memorial Pathological Scholarships of £10 each; the Tibbits Memorial Prize, value 7 guineas, for proficiency in practical surgery; the Committees' Gold and Silver Medals for fifth or sixth-year students, for general proficiency; the Augustin Prichard Prize, value about 6 guineas, for proficiency in anatomy; the Henry Clark Prize, value 11 guineas, for proficiency in gynaecology; the Crosby Leonard Prize, value 6 guineas, for proficiency in surgery; the Supple Surgical Prize, a gold medal and 7 guineas; the Supple Medical Prize, a gold medal and 7 guineas; the Henry Marshall Prize, value £12, for dressers; the H. M. Clarke Scholarship, value £15, for proficiency in surgery; the Sanders Scholarship, value £22 10s., for general proficiency; the Barrett-Roué Scholarship for proficiency in diseases of the nose, throat, and ear, or skin or eye, value £17, open to men only; Lady Habersfield Scholarship, value about 25 guineas; Bristol and Bath City Scholarships and the Scholarships offered by the counties of Gloucestershire, Somerset, Wilts, Dorset, etc., are tenable in the university.

One or more Fellowships of not less than £100 per annum are allocated by the Colston Research Society for medical research.

A Beaverbrook Fellowship, tenable for three years, is open to all members of the university holding a medical qualification.

University graduate scholarships are open to graduates of not more than one year's standing.

The Michael Hiatt Baker Scholarship of the value of £200 per annum, open to a graduate from New Zealand may be held in the medical faculty.

The Markham Skerritt Memorial Prize is awarded every three years to that member of the university, not a member of the medical board, who, in the opinion of that board has published the best original work during the three years.

The Paul Bush Gold Medal is awarded in alternate years to the best resident medical officer at the Bristol Royal Infirmary.

Fees.—The fee for all the courses required for the medical curriculum including hospital practice, is 205 guineas, paid by annual instalments.

Further information as to scholarships, curricula, and fees can be obtained from the Dean of the Faculty of Medicine, or the Registrar of the University, Bristol.

University of Durham College of Medicine

This constitutes the Medical School of the Faculty of Medicine of the University of Durham, and is in the neighbouring city, Newcastle-upon-Tyne. Its classes and lectures are arranged to meet the requirements of the university in all the degrees which the latter grants in the Faculty of Medicine, and also those of the other-examining bodies. Hospital practice is carried out at the Royal Victoria Infirmary, a general hospital containing more than 700 beds, where there are facilities for the study of the various special subjects. Students do their practical midwifery at the Princess Mary Maternity Hospital, which contains 90 beds, and has an annual indoor and outdoor attendance on 3,000 cases. In the Heath wing of the school itself there is a gymnasium and a set of rooms for the separate use of the students. The bacteriological department is adjacent to Armstrong College.

The Newcastle-upon-Tyne Dental Hospital and Sutherland Dental School is a component part of, and constitutes the dental department in, the College. The dental hospital, erected within the grounds of the Royal Victoria Infirmary and equipped on the best modern lines, was opened in 1931, and it is possible to undertake the whole of the dental curriculum (that is, systemic lectures, dental and general hospital practice, together with mechanical pupillage) at the College. The Dental Board of the United Kingdom recognizes the school for the purpose of granting its bursaries to students who are able to comply with the conditions laid down by the Board.

Post-Graduate Instruction.—A comprehensive series of post-graduate courses are arranged to enable practitioners to take advantage of the facilities for laboratory work and clinical study afforded by the College, the Royal Victoria Infirmary, and other associated hospitals; and in order to meet the varied requirements of practitioners there are general and special courses in the winter and summer sessions, as well as an intensive course in the summer vacation. Courses of instruction are given for the B.Hy. and D.P.H.

Students' Union.—A Students' Union has been erected and furnished at a cost of over £54,000, and is in daily use. Separate accommodation (non-residential) is provided for men and women students.

Appointments.—Assistants in the pathological department, eye department, throat and ear department, and department for skin diseases, are elected periodically. Clinical clerks and dressers are appointed every three months. Resident appointments at the Infirmary are made every six months, and each year medical and surgical registrars (who also act as tutors) are appointed from candidates who have previously held resident appointments at any recognized hospital. These latter posts afford an excellent opportunity for post-graduate study, not only at the Infirmary, but also in the departments of anatomy, physiology, pathology, and bacteriology of the College.

Scholarships.—University of Durham Entrance Scholarship, £25 a year for four years; Pears Entrance Scholarship, £40 a year for three years (awarded every third year); Heath Entrance Scholarship (from Kieper Grammar School), £60 (renewable); Province of Durham Masonic (Entrance) Scholarship, £60 (renewable); Heath Scholarship for surgery, £200, available every second year; Rutherford Morison Surgical Scholarship, £180, available every third year.

The following scholarships are tenable for one year—namely: Tulloch Scholarship for elementary biology and organic chemistry, £20; Dickinson Scholarship for medicine, surgery, midwifery, and pathology, £20; Charlton Scholarship for medicine, £25; Gibb Scholarship for pathology, £28; Luke Armstrong Scholarship for comparative pathology, £25; Stephen Scott Scholarships for anatomy and physiology, two of £50 each; Philipson Scholarships for highest marks in Final M.B., B.S. Examination, two of £45 each; Goyder Memorial Scholarship for clinical medicine and clinical surgery, interest on £325; Hamilton Drummond Memorial Scholarship, in aid of research in clinical surgery, about £50; Gibson Prize for midwifery and diseases of women and children, £10; Turnbull Prize and Silver Medal for surface anatomy; Outterson Wood Prize for psychological medicine, £10; and Sewell Memorial Prize and Silver Medal for clinical pathology. Approved applicants may obtain special grants for surgical research from the Stephen Scott Research Fund.

Fees.—The composition fee for lectures for medical students at the college is £132. Composition fee for hospital practice,

£46, plus £2 2s. yearly for three years, payable to the Committee of the Royal Victoria Infirmary. For dental students the composition fees amount to £236 for the B.D.S. and to £221 for the L.D.S., covering all systematic lectures and laboratory work at the College, general and dental hospital practice, and mechanical pupillage. Other information should be sought from the Dean of the College, University of Durham College of Medicine, Newcastle-upon-Tyne.

Leeds

The School of Medicine—which is open to both male and female students—in this city forms the teaching centre of the Medical Faculty of the University of Leeds, and is situated in immediate proximity to the General Infirmary, where students sufficiently advanced receive their clinical instruction. The main buildings, opened in 1894, contain excellent dissecting rooms, well-arranged laboratories for physiology, lecture theatres, and classrooms. In addition, there is a well-equipped library and reading room and a museum of anatomy. The comfort of the students is secured by means of common rooms and a refectory. Extensions of the medical school buildings were opened in October, 1930, and the Algernon Firth Institute of Pathology in April, 1933. This last houses the Departments of Pathology and Bacteriology, and Experimental Pathology and Cancer Research, including the Charles Brotherton Pathological Museum. The General Infirmary has 628 beds, and includes ophthalmic and children's wards, a large out-patient department, and the Ida and Robert Arthington Semi-convalescent Hospitals, Cookridge. The West Riding Mental Hospital at Wakefield is available for the study of mental diseases. Students also attend the practice of the Hospital for Women and the Leeds Maternity Hospital, and may attend also at the Leeds Public Dispensary.

Appointments.—Physicians' clerks and surgical dressers are appointed every six months; clerks in the children's department, orthopaedic dressers, ophthalmic and aural dressers, gynaecological ward clerks, maternity clerks, assistant physicians' clerk, dermatological clerks, assistant surgeons' dressers, dressers in the casualty rooms, junior and senior post-mortem clerks, laboratory assistants and dressers in the venereal clinic every three months. After graduation a considerable number of resident and other appointments become available in the Leeds General Infirmary, Leeds Public Dispensary, Hospital for Women and Children, West Riding Mental Hospital, etc., occupying periods of from six to twelve months at rates varying from £20 to £150 per annum.

Scholarships.—The university awards annually on the results of the first examination a scholarship in the form of free admission to the lectures and classes given in the School of Medicine. The university also awards a scholarship on the results of the second examination, of the value of £68, in the form of free admission to the clinical teaching of the Infirmary.

Fees.—It is estimated by the authorities that the approximate cost of medical education to a student in this university is £370, plus, of course, the expenses of living during the five and a half years covered by the curriculum. The composition fee for the course for the first, second, and third examinations, and for the clinical work at the Infirmary, is £242. The composition and clinical fee for those who have passed the second examination is £153.

Further information can be obtained from the Academic Subdean or Clinical Subdean, School of Medicine, Leeds.

Liverpool

The Medical School of this city is part of the university, and, owing to the enlightened liberality of several men of wealth, is exceptionally well provided with special laboratories, as well as with ordinary spacious and well-equipped classrooms and laboratories for the instruction of students proceeding to medical degrees and diplomas in special and ordinary subjects. All the laboratory and other rooms are situated close to one another and inter-communicate, together forming large blocks of buildings. The work of students throughout all stages of their career is arranged upon very satisfactory lines, and the teaching hospitals, of which a list is given below, have amalgamated to form the clinical school of the university.

The nature of the appointments open to past and other students at this school will be gathered from the account which follows of the hospitals forming its clinical department.

Scholarships.—The awards made each year to successful students total over £1,500. They include the following: two Holt Fellowships, one in pathology, the other in physiology; a Robert Gee Fellowship in anatomy; two John Rankin Fellowships in anatomy; a John W. Garrett International Fellowship in bacteriology; a Johnston Colonial Fellowship in biochemistry; an Ethel Boyce Fellowship in gynaecology; and a Thelwall Thomas Fellowship in surgical pathology; one Lady Jones Fellowship in orthopaedic surgery (value of Fellowships: one at £200, three at £150, two at £120, four at £100); a University Scholarship of £50, awarded on the results of Part I of the Final M.B. Examinations; a Ridgway Research Scholarship (£94); a T. J. Hughes Research Scholarship (£72); a Scholarship in mechanical dentistry of £20; two Lyon Jones Scholarships, of the annual value of £19 each for two years, awarded one on the results of the First M.B. Examination, the other on the Second M.B.; the Derby Exhibition of £15; the Clinical School Exhibition of £15; the Owen T. Williams Prize; the Torr Gold Medal in anatomy; John Rankin Exhibition in practical anatomy, £23; the George Holt Medal in physiology; the Kanthack Medal in pathology; Mitchell Banks Medal in anatomy; the Robert Gee Prize of £5 5s. in children's diseases; Mary Birrell Davies Memorial Scholarship (women), £60 per annum for four years; Robert Gee Entrance Scholarship (men), value of £42 10s. per annum for four years; Dental Operating Prizes (four); Orthodontia Prizes (two); Samuels Memorial Scholarships, three at £27 each; one Thomas H. Bickerton Prize in anatomy; Dr. N. E. Roberts Prize in zymotic diseases; Adam Prize in Pathology; Rich Prize; Ash's Prize in dental surgery, value £2 2s.; Gilmour Medal; and other entrance scholarships. In addition, a number of gold and silver medals have recently been instituted in the following subjects: pharmacology, surgery, forensic medicine and toxicology, public health, medicine, orthopaedic surgery, obstetrics and gynaecology, and laryngology and otology.

Fees.—Information as to the fees for the courses of instruction provided by the schools should be sought from the Dean of the Medical Faculty.

The Clinical School

As many as nine hospitals have combined to form the clinical school of the university, these being: the Liverpool Royal Infirmary, the David Lewis Northern Hospital, the Liverpool Royal Southern Hospital, the Liverpool Stanley Hospital, the Royal Liverpool Children's Hospital, the Women's Hospital, Liverpool, the Liverpool Maternity Hospital, the Eye and Ear Infirmary, and St. Paul's Eye Hospital. Between them they provide over 1,500 beds.

Manchester

The staff of the Medical School in this city constitutes the Medical Faculty of the Victoria University, all the arrangements for the instruction of students, both in their earlier and their later studies, being of an elaborate nature. The clinical work of the undergraduates is done chiefly in connexion with the Royal Infirmary, an institution which itself contains 590 beds, and has associated with it a large convalescent home (132 beds) and a Central Branch Hospital (54 beds). The courses in mental diseases are partly taken in the County Mental Hospitals at Prestwich and Macclesfield. Instruction in practical gynaecology and midwifery is given at the Royal Infirmary and the St. Mary's Hospitals.

Clinical Work.—The Royal Eye Hospital, the Hospital for Diseases of the Skin, the Manchester Northern Hospital for Women and Children, the well-known Hospitals for Children at Pendlebury, and St. Mary's Hospitals for Women and Children, the Manchester Hospital for Diseases of the Ear, Monsall Fever Hospital, the Christie Cancer Hospital and Holt Radium Institute, the Hospital for Consumption and Diseases of the Throat and Chest, the Ancoats Hospital, and the Salford Royal Hospital, all make arrangements for the instruction of students.

Appointments.—The following are among the appointments open to past and present students of this school in connexion with its arrangements for clinical tuition: two pathological registrars, at £100 and £50 per annum; two medical registrars at £75 per annum; a cardiographic registrar, at £150

per annum; a medical tutor, at £30 per annum; a director of the clinical laboratory, at £400 per annum, and two assistants, at £350 and £300; three assistant medical officers, each at £35 per annum; four chief assistants to surgical units, £250 per annum; chief assistant to neuro-surgical service, £350 per annum; chief assistant to orthopaedic department, £250 per annum; medical registrar to out-patient department, £150 per annum; assistant surgical officers, aural department at £35 per annum; seven anaesthetists from £75 to £125 per annum each; three anaesthetists at central branch, £25 to £100 per annum; one resident medical officer, one year, £200 per annum; one resident surgical officer, one year, £200 per annum; three resident medical officers for Central Branch, one at £200 and two at £100 per annum; one assistant resident surgical officer, £150 per annum; one resident medical officer at the Convalescent Hospital at Cheadle, £250 per annum; two assistant medical officers to radiological department, £150 and £105 per annum; medical officer, physio-therapeutic department, £150 per annum; assistant surgical officer, gynaecological department, £35 per annum; assistant to the dermatologist, £20 per annum; and three assistant surgical officers for Central Branch, £75 per annum; ten house-surgeons and eight house-physicians, appointed during the year for periods of six months, at a salary of £50 per annum. Resident officers are appointed to the gynaecological, the eye, and the ear and throat departments every three months. Clinical clerks and surgical dressers are appointed to the various departments of the hospital every three months. Non-resident clinical assistantships for qualified medical men and women, tenable for six months, at an honorarium of £35.

Entrance and other Scholarships.—The following are among the scholarships obtainable by students of the school: Rogers and Seaton Scholarships in Arts (in alternate years), £40 per annum, tenable for two years. Three Hulme Scholarships, tenable for three years, of £35, one being awarded annually for proficiency in subjects of general education. Two James Gaskill Scholarships of £35, tenable for two years, one being awarded annually for proficiency in the branches of mechanics and chemistry. A Dora Muir Scholarship, £30 per annum, tenable for three years, and open to the competition of women students only. This is awarded triennially. Sir J. P. Kay-Shuttleworth Scholarship, £30 per annum, tenable for three years, awarded triennially, open to the competition of scholars from Sedburgh School, Giggleswick School, and Burnley Grammar School; subjects—mathematics, chemistry, and mechanics. Dreschfeld Memorial Scholarship, value £20, tenable for two years and awarded triennially on the result of the Entrance Examination. John Russell Medical Entrance Scholarship, awarded annually, value £45. Two Dauntsey Junior Medical Scholarships, value £50 each, tenable for one year, for candidates who have not commenced the second year of study leading to a medical qualification; subjects—chemistry, physics, botany, and zoology. One Dauntsey Senior Medical Scholarship, £50 for one year, awarded on results of Second M.B. Examination. Two Entrance Scholarships in medicine, value 160 guineas, awarded annually for proficiency in arts or science respectively. Tom Jones Exhibition in anatomy, £25, offered annually. A Robert Platt Physiological Scholarship of £90, tenable for one year. A Leech Fellowship of £100 for original research after graduation. A Graduate Research Scholarship in medicine, value £70, tenable for one year, awarded annually for proficiency shown at Final M.B. Examination. Two Dunville Surgical Prizes, each value £15, awarded annually at graduation. The Tom Jones Memorial Surgical Fellowship, value £105, tenable for one year, usually awarded annually. The Turner Medical Prizes, value 10 guineas each, awarded annually for proficiency in certain subjects of the Final M.B., Ch.B. Examination. The John Henry Agnew Prize of £30, awarded annually for proficiency in the diseases of children. The Ashby Memorial Scholarship, tenable for one year (£100), for research in the diseases of children; offered triennially. Sidney Renshaw Prizes in physiology; offered annually (£10 and £20). Wild prize in pharmacology (£10). The John Henry Agnew Fellowship in diseases of children, £120, offered triennially. Eliza Marple Holt Post-Graduate Medical Scholarship for Women, £60 for one year, offered biennially. The details and regulations of the Dickinson Scholarships—(1) for anatomy, (2) for pathology, (3) Research Scholarship in surgery, and (4) Travelling Scholarship in medicine—may be obtained from the Secretary to the Trustees. The Morrison Watson Fellowship for research in anatomy is offered annually, value £150; also the Sheridan Delepine Fellowship in preventive medicine, value £300, is offered biennially. The Sam Gamble Scholarships—the trustees are prepared to award four scholarships of not less than £40 per annum, tenable for not more than four years, to women students who have passed the First M.B. Examination; the conditions can be obtained from the Registrar. The Knight Prize of £50 for original research in the psychological factors in the causation of mental disorder

—open to holders of the Diploma in Psychological Medicine or medical practitioners who have been registered in the university as candidates for that diploma. Pilkington Fellowship in Cancer research £300 for one year.

Fees.—The composition fee for the university course in medicine is 114 guineas for men, 112 guineas for women, payable in four instalments of 28½ and 28 guineas respectively, but this sum does not include the fee to cover the work required for the First M.B. Examination. This is £42, payable in one sum. Hospital fees are additional, and usually amount to about 90 guineas.

A prospectus and further information about the school and scholarships may be obtained from the Registrar.

Sheffield

In this city the Medical School is one of the departments of the university, being conducted and controlled by its Medical Faculty, and occupying practically the entire north wing of the quadrangle of the university buildings overlooking Weston Park. The laboratories and lecture rooms connected with the subjects of the first and second examinations—namely, chemistry, physics, biology, anatomy, and physiology—are, both as regards structural arrangement and scientific equipment, on the most modern and complete lines.

For students of pathology and bacteriology there are laboratories replete with everything necessary for the most advanced work, and a large pathological museum, which is open daily. In addition, there is a large library and reading room. There are a number of recreation, athletic, and other societies, all under the management of an annually elected students' representative council, and large and comfortable common rooms for both men and women students. There are also two student unions—one for men and one for women students. Thanks to the generosity of Alderman J. G. Graves, a well-equipped union building is in course of erection, and when complete will add very materially to the amenities of the students' social life.

There is ample hostel accommodation for women students, and in the near future similar accommodation will be available for men. In the university buildings there is a refectory open to all students of the school, and a university journal is published each term; the Medical School also publishes a journal. The ordinary clinical work of the school is done at the Royal Infirmary and Royal Hospital, which have amalgamated for the purpose of clinical instruction, and provide over 800 beds for medical, surgical, and special cases, including diseases of the eye.

In addition, the Royal Infirmary has special departments for the treatment of diseases of the skin and ear, with beds assigned to them; whilst at the Royal Hospital there are special out-patient departments for diseases of the throat, ear, skin, orthopaedics, and mental diseases. The medical and surgical staffs attend daily, and give clinical instruction in the wards and out-patient rooms. Clinical lectures in medicine and surgery are given weekly. Instruction in the practical administration of anaesthetics is given at either institution by the anaesthetists, and the post-mortem examinations at both institutions are in charge of the Professor of Pathology, and afford ample material for study of this subject. Students are able to attend the practice of the Jessop Hospital for Diseases of Women and the Hospital for Sick Children, while special courses on fevers are given at the City Fever Hospital, and on mental diseases at the South Yorkshire Mental Hospital.

Appointments.—The following appointments are open to all students who have passed their examinations in anatomy and physiology: (1) casualty dresserships, (2) surgical dresserships, (3) medical clerkships, (4) pathological clerkships, (5) ophthalmic clerkships, (6) clerk to the skin department, etc. These appointments are made for three months, commencing on the first day of October, January, April, and July.

Scholarships.—Entrance Medical Scholarship, covering cost of tuition fees for a degree course in the Faculty of Medicine, open to both sexes. Six Edgar Allen Scholarships of £100 a year for three years may be held by students taking the degree course in medicine. Two Town Trustees' Scholarships, each of the value of £50 a year, tenable for three years, for boys or girls who have been educated in a Sheffield secondary school for a period not less than two years

immediately preceding the examination. Four Town Trustees' Scholarships, value £50 a year, for boys or girls under 19 years of age educated in any school in Sheffield, secondary or otherwise. Town Trustees' Fellowship, value £75, tenable for one year. Mechanics' Institute Scholarship, value £50 (with remission of fees), tenable for one year, and renewable for a second year. The Frederick Clifford Scholarship, value about £50, tenable for two years. Kaye Scholarship, value £60, for proficiency in anatomy and physiology. Gold and bronze medals are also awarded for proficiency in various subjects.

Fees.—Students in the Faculty taking their complete medical course in the university pay an inclusive composition fee of £42 for each of the first five years and £28 for the sixth year. The composition fees for the dental courses are as follows: for B.D.S., first and third years, £80; second, fourth, and fifth years, £30; for L.D.S., first and second years, £80; third and fourth years, £30. The fees for special courses taken separately can be ascertained by inquiry of the Dean.

Note.—To non-British subjects—that is, students from outside the British Empire—an additional 20 per cent. will be charged on all fees.

Welsh National School of Medicine

The next session opens on October 2nd. All classes are open to both men and women students. Particulars relating to the admission of students can be obtained on application to the Provost, or to the Secretary, Welsh National School of Medicine, The Parade, Cardiff.

The following is a list of heads of departments: materia medica and pharmacology, Dr. Reginald St. A. Heathcote; pathology and bacteriology, Professor J. B. Duguid; medicine, Professor A. M. Kennedy; surgery, Professor A. W. Sheen; obstetrics and gynaecology, Professor G. I. Strachan; preventive medicine, Professor R. M. F. Picken; tuberculosis, Professor S. Lyle Cummins.

During the first three years students complete the first part of their scheme of study for the degrees of M.B., B.Ch. by taking the following courses, which also qualify for the B.Sc. degree:

(a) In the first year the preliminary subjects of physics, chemistry, botany, and zoology are taken. (Courses in these subjects can be taken in any of the four constituent colleges of the University of Wales.)

(b) In the second year the subsidiary subject of organic chemistry is taken.

(c) In the second and third years the ancillary subjects of human anatomy and physiology are taken. (Courses under (b) and (c) are taken at the University College of South Wales and Monmouthshire.)

SCOTLAND

As will be gathered from the following paragraphs, the facilities for acquiring a medical education in Scotland are very ample, whether the student be proceeding to a university degree or to a diploma. To the descriptions of the different Scottish medical centres is in some cases added an account of hospitals which either play an official part in the education given to students as yet unqualified, or offer valuable opportunities for post-graduation work.

Aberdeen

The school is conducted by the Faculty of Medicine. This comprises twelve chairs, from which instruction is given in all the main branches of medical science—namely, biology, physics, chemistry, anatomy, physiology, materia medica, pathology, bacteriology, surgery, medicine, and midwifery. Courses of instruction in forensic medicine, public health and infectious diseases, tropical medicine, medical ethics, tuberculosis, and clinical methods are conducted by lecturers appointed by the University Court. Special opportunities for practical instruction are afforded in the laboratories and museums attached to the departments.

Clinical instruction is obtained in the Royal Infirmary, the Royal Mental Hospital, the Sick Children's Hospital, the City Fever Hospital, the General Dispensary,

Maternity, and Vaccine Institution, and the Ophthalmic Institution. Courses of practical instruction are given in diseases of children at the Sick Children's Hospital; in fevers at the City Fever Hospital; in mental diseases at the Royal Mental Hospital; in diseases of the ear, nose, and throat at the Infirmary and Dispensary; in diseases of the eye at the Infirmary and Eye Institution; in venereal diseases and diseases of the skin at the Royal Infirmary.

The degrees granted in medicine are: Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.). A diploma in public health is conferred after examination on graduates in medicine of any university of the United Kingdom.

The degree of Ph.D. is also granted in this faculty.

Bursaries, scholarships, and fellowships, to the number of fifty, and of the annual value of £1,200, may be held by students of medicine in this university. The bursaries range in value from £10 to £50 per annum, and are tenable for periods from one to five years.

Fees.—An inclusive fee of 126 guineas is payable for instruction within the university, and the fee for the degrees of M.B., Ch.B. is 33 guineas. The total cost, including hospital fees, class and matriculation fees, and degree fees, is about £240.

Edinburgh

There are two Schools of Medicine: the School of the University, and the School of Medicine of the Royal Colleges of Physicians and Surgeons of Edinburgh.

THE UNIVERSITY SCHOOL.—This school, in addition to other resources of the university, has the following means of affording practical instruction: Royal Botanic Garden, Herbarium, and Museum; zoological laboratory and museum of science and art; physical laboratory; chemical laboratories; dissecting room, bone room, and anatomical museum; physiological laboratory; medical jurisprudence laboratories; John Usher Institute of Public Health; materia medica museum and laboratory; post-mortem department of the Royal Infirmary and University Pathological and Bacteriological Laboratory; tutorial classes of practice of physic, of clinical medicine, and clinical surgery, surgery and midwifery; and the practice of certain other hospitals.

Fees.—The sessional fee for chemistry, anatomy lectures, physiology, pathology, materia medica, surgery, medicine, and midwifery is £6 6s. each. Physics, botany, zoology, forensic medicine, and public health, £5 5s. Practical zoology, practical anatomy (summer), morbid anatomy, practical materia medica, mental diseases, practical pathology, clinical midwifery, and medical entomology and parasitology, £4 4s. Experimental physiology, diseases of tropical climates, practical botany, histology, child life and health, operative surgery, clinical surgery (per term), and clinical medicine (per term), £3 3s. Practical anatomy (winter), £6 18s. 6d. Practical chemistry, £4 14s. 6d., chemical physiology, surgical pathology, and infectious diseases, £1 11s. 6d. Tuberculosis, diseases of the eye, diseases of the larynx, ear, and nose, diseases of the skin, and venereal diseases, £2 12s. 6d. Advanced bacteriology, £7 17s. 6d. Clinical gynaecology, regional anatomy, and applied anatomy, £2 2s.

Scholarships.—There are many funds for the assistance of students by means of bursaries, scholarships, exhibitions, and money awards from the beginning to the end of their undergraduate career. In addition, there are funds which help those who have taken a first degree in medicine and surgery to continue at work as research students. The value of these awards, and the conditions attaching to them, are so varied that those interested should consult the prospectus of the school itself.

THE SCHOOL OF MEDICINE OF THE ROYAL COLLEGES.—This school is composed of Lecturers licensed by the Royal College of Physicians and the Royal College of Surgeons and in most cases also recognized by the University of Edinburgh through their *licentia docendi*; for the sake of convenience they lecture in separate buildings near to the Royal Infirmary, but form a single corporate body governed by a Board elected by the Royal Colleges of Physicians and Surgeons and by the Lecturers. This Board, with the assistance of the standing committees of the school, supervises the whole management and

especially the maintenance of the efficiency and discipline of the school. The buildings at present utilized for the purposes of lecturing are the following: (1) Surgeon's Hall, Nicolson Street; (2) New School, Bristo Street. Clinical classes are held in the Royal Infirmary, Royal Maternity Hospital, and other institutions. The teaching is similar to that of the Scottish universities, and the students receive similar certificates at the close of each session. The courses on the special subjects are also conducted by teachers specially qualified in each branch. The fees payable for class and other instruction, and including the sums payable before admission to the examination of the Conjoint Board for the triple qualification, amount to about £180. The Calendar, giving full information regarding classes and fees, can be obtained (price 9d., post free) on application to the Dean of the School, Surgeon's Hall, Edinburgh.

WOMEN STUDENTS IN EDINBURGH.—Until the close of the summer session of 1916 women students intending to proceed to graduation in the University of Edinburgh, as well as those entering for the triple qualification of the Royal Colleges of Edinburgh and Glasgow, received their training in the Edinburgh School of Medicine for Women. Now women students study under the same conditions as men, and may obtain either the university degree or the diploma of the Royal Colleges. In the university systematic lectures are given to them by the professors in the ordinary classes, which are therefore mixed. In clinical surgery, however, the women students are restricted to the wards of one charge. The particular wards are changed periodically, each of the surgeons to the Infirmary taking the women students in rotation. With few exceptions, prizes, scholarships, bursaries, and similar distinctions are open to women under the same conditions as for men. The women students also have the same privileges as in the past have been given to the men of attending classes taught by the recognized lecturers of the School of Medicine of the Royal Colleges. Most of the students' societies are open to women, with the exception of the University Union and the Royal Medical Society. Their place is taken by the Women Students' Union and the Women's Medical Society. There is also a Women's Athletic Club, with playing fields gifted to it by the university. The membership of the Royal College of Physicians and Fellowships of the two Royal Colleges are also open to women. Information on matters connected with women's studies may be obtained from the Adviser of Women Students, The University, Edinburgh.

Glasgow

THE UNIVERSITY SCHOOL FOR MEN.—The whole course of study required for graduation (M.B., Ch.B.) at the University of Glasgow can be taken here. Besides ample provision for lectures there is practical and clinical work at the hospitals, and practical courses are conducted in the laboratories of the following departments: pathology, public health, pharmacology, physiology, surgery, anatomy, chemistry, zoology, physics, and botany; the Botanic Garden and the Hunterian Museum are also open to students. Well-equipped new buildings have been provided for zoology, practical anatomy, and operative surgery, as well as for pathology. The classrooms and laboratories for the departments of botany, physics, physiology, pharmacology, materia medica, medical jurisprudence, and public health are also of recent erection, and are elaborately equipped. In addition to the regius chairs and the chair of pathology at the university, there are chairs of medicine, surgery, obstetrics, and pathology at the Royal Infirmary; and a number of university lectureships in clinical medicine, clinical surgery, venereal diseases, laryngology, dermatology, otology, psychological medicine, tuberculosis, pathological biochemistry, and electrical diagnosis and treatment have been founded there. Other chairs have been founded at the university in bacteriology, organic chemistry, physiological chemistry, applied physics, public health, and paediatrics. There are also lectureships on the surgical

and medical diseases of children and on electrical diagnosis and therapeutics. The university, in short, has made great and successful efforts to extend and improve the accommodation of the medical departments, to strengthen the teaching staff, and to encourage post-graduation and research work. A diploma in public health is now also granted. Three very extensive general hospitals in the city afford exceptional opportunities for clinical instruction—namely, the Western Infirmary (600 beds), near the university, to which the Regius Professors are attached; the Royal Infirmary (824 beds); and the Victoria Infirmary (380 beds); while the Royal Mental Hospital Gartnavel (500 beds), the Royal Hospital for Sick Children (350 cots), the Royal Maternity and Women's Hospital (114 beds), the Glasgow Eye Infirmary (100 beds), the Ophthalmic Institution (35 beds), the fever hospitals at Belvidere (680 beds), Ruchill (540 beds), and Mearnskirck, and other institutions afford facilities for the practical study of special branches. The large general hospitals of the parish council are now also available for clinical instruction in medicine and surgery. Information regarding post-graduate study will be found at page 431.

Bursaries.—Bursaries confined to the Medical Faculty amount in annual value to about £1,000, while bursaries in any faculty, amounting to about the same annual sum, may be held by students of medicine, a number of both sets being open to women. Several valuable scholarships may be held by medical students who have graduated in arts.

The following bursaries are open for competition to students entering on their first session of attendance in the Faculty of Medicine: Davidson Bursary, annual value £40, tenable for four years, for students who propose before entering the Faculty of Medicine to take the degree of B.Sc. in pure science, including in their curricula anatomy and physiology. Highland Society (Glasgow) Bursaries, annual value £25 each, tenable for five years, for students of Highland descent, open to women; two bursaries vacant each year. Logan Bursary, annual value £25, tenable for four years, open to women. Robina Eckford MacBrayne Scholarship, annual value £50, tenable for three years. Marshall Bursary, annual value £24, tenable for four years. Merchants' House Bursary, annual value £35, tenable for four years, open to women. John Oliphant Bursary, annual value £35, tenable for six years. James A. Paterson Bursaries, three each year of the annual value of £35, £25, and £15 respectively, each tenable for four years; students entering their second session are also eligible; open to women; examination in mathematics and natural philosophy.

Candidates for the aforementioned bursaries must take the university general Bursary competition, which is held each year in the month of June.

In addition, the following bursaries, scholarships, and prizes are open to students prosecuting their studies in the Faculty of Medicine: Arbroath Bursary, annual value £40, tenable for three years, is awarded by the Senate, on the recommendation of the Faculty of Medicine, to the student who is of the highest merit among the candidates as shown by their class records and their performances in the First and Second Professional Examinations. Arthur Bursary, annual value £20, tenable for three years, awarded to the woman student who takes the highest place among the Queen Margaret College candidates at the First Professional Examination. Mary Allan Bell Bursaries (five), annual value £50 each, tenable for three or four years, for students who have gone through the curriculum in arts; special examination, tenable also in theology or law. Brisbane Bursary, annual value £50, tenable for four years; candidates must be under 22 years of age, and must have taken the degree of M.A. William Gardiner Bursary, annual value £18, tenable for two years, awarded on results of the First and Second Professional Examinations in the subjects of physiology, chemistry, and physics. Dr. Thomas Gibson Bursary, annual value £50, tenable for four years; open to medical students entering on their second winter who are preparing for service as medical missionaries. Johnston Bursaries (two), annual value £25 each, tenable for three years, for eminence in the work and examinations of the first and second years of the curriculum. Lorimer Bursaries (six), value £20 each, tenable for one year, are awarded to the best students in each of the following classes: botany, zoology, physics, chemistry, anatomy, physiology. Macfarlane Bursary, annual value £40, tenable for three years, for students who have attended the first session of their professional study in the university; examination in elementary anatomy, elementary chemistry, and botany. Mackintosh Bursary, value £31, tenable for one year, open to medical students of either sex who have attended one of the courses of lectures on insanity; examination in that subject. John Monteith Bursary, annual value £21, tenable for two years,

is awarded annually to the student who gains the highest number of marks in the subjects of anatomy and physiology at the professional examinations held during the previous year. Rainy Bursary, annual value £50, tenable for two years, for students entering on their third session of medical study; awarded to the candidate whose aggregate of marks in the subjects of anatomy and physiology of the Second Professional Examination, and in chemistry, botany, and zoology of the First Professional Examination, is the highest. A. and B. Stewart Bursaries, annual value £50 each, tenable for three years, for students who have gone through the arts curriculum; there is a special examination. Walton Bursary, annual value £40, tenable for four years; the Earl of Sandwich has the right of appointing to the bursary one of two students nominated by the Senate. Weir Bursary, value £25, tenable for one year, awarded on the results of the Second and Third Professional Examinations. Barbour Scholarship in anatomy or physiology, annual value £250, tenable for two years. Joseph Coats Memorial Scholarship, value £85, tenable for one year, for research in pathology, may be held concurrently with the Perman Memorial Scholarship (q.v.). Faulds Fellowship, annual value £250, tenable for three years, for medical research. Foulis Memorial Scholarship in pathology, value £50. Four McCunn Medical Research Scholarships, value £200 each, tenable for one year. Perman Memorial Scholarship, value £50, tenable for one year, for research in pathology, may be held concurrently with the Joseph Coats Memorial Scholarship (q.v.). The Junior Arnot Prize of about £15; the Senior Arnot Prize of £25. Three Bellahouston Gold Medals. The Brunton Memorial Prize of about £20. The Maceven Medal in surgery. The Captain H. S. Ranken V.C. Memorial Prize of £5. The Straits Settlements Gold Medal. The West of Scotland R.A.M.C. Memorial Prize of about £15.

The Carnegie Trust for the Universities of Scotland is empowered to pay the whole or part of the university ordinary class fees of students of Scottish birth or extraction, under conditions given in the University Calendar, and summarized at page 404 of this issue. Scholarships and Fellowships are offered by the Carnegie Trust in science and medicine for post-graduation study.

Fees.—The matriculation fee for each year is £2 12s. 6d. In most cases the fee for each university class is £6 6s., but in some cases it is £4 4s. For hospital attendance at the Western Infirmary students pay £12 12s. for a perpetual ticket, or £1 11s. 6d. for a single term ticket, with an additional fee of £5 5s. for each winter and £2 12s. 6d. per term for each clinical course. The fees are the same at the Royal Infirmary. The university fees for the four professional examinations total £34 13s. For the whole curriculum the fees for matriculation, class attendance, hospital attendance, and professional examinations amount to about £250.

For further information apply to the Registrar, Glasgow University.

QUEEN MARGARET COLLEGE.—Includes the Women's Medical School of the University of Glasgow. The courses of study, degrees, regulations, fees, etc., are the same as for men. Women students have at Queen Margaret College reading rooms, library, and the offices of administration. They are taught in classes together with men students, and have all the rights and privileges of university students. Their clinical studies are taken in the Royal Infirmary, the Western Infirmary, and the Victoria Infirmary; also *inter alia* in the Royal Hospital for Sick Children, the Glasgow Ear Hospital, the Royal Asylum, Gartnavel, Hawkhead Asylum, the Ophthalmic Institution, the City of Glasgow Fever Hospitals, Belvidere and Ruchill, and the Glasgow Royal Maternity and Women's Hospital.

Scholarships.—The Arthur Scholarship, annual value £20, tenable for three years. Open to competition by medical students of first year at the First Professional Examination in October, 1934. This scholarship is restricted to women medical students.

Full information can be obtained from the Dean of the Faculty of Medicine, University of Glasgow, or the Secretary to the Mistress of Queen Margaret College, University of Glasgow.

Board for Students.—University Halls of residence for women students, Queen Margaret Hall and Robertson Hall, are situated near the college and the other university buildings. The cost of board and residence is from 35s. to 42s. a week, according to accommodation. Applications to be made to the Wardens. Another residence near the college is South Park House, Ann Street, belonging to the Student Christian Movement, and open to women students in Glasgow. Cost of board is from 32s. to 35s. weekly. Applications to be made to the Warden.

ST. MUNGO'S COLLEGE.—This is the Medical School of the Royal Infirmary, which is the largest general hospital in Glasgow. The Infirmary is situated in Cathedral Square, Castle Street, and has car communication with every part of the city. St. Mungo's College is in the Infirmary grounds, and affords full courses in all the subjects of the medical curriculum, and in all the medical subjects of the dental curriculum.

The Infirmary has (including the ophthalmic department) 782 beds—542 for surgical and 240 for medical cases. There are special beds and wards for diseases of women, of the throat, nose, and ear, burns, and septic cases. In the out-patient department in 1932 over 111,000 patients were treated. In addition to the large medical and surgical departments, there are departments for special diseases—namely, diseases of women, of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. There is also a fully equipped electrical pavilion, with the latest and most improved apparatus for diagnosis and treatment.

Appointments.—Five house-physicians and eleven house-surgeons, who must be fully qualified, are appointed every six months, and board in the hospital free of charge. Clerks and dressers are appointed by the physicians and surgeons. As many cases of acute diseases and accidents of a varied character are received, these appointments are very valuable.

Fees.—The average class fee is £3 3s. for summer classes and £4 4s. for winter classes. The fees for all the lectures, practical classes, and hospital attendance necessary for candidates for the diplomas of the English or Scottish Colleges of Physicians and Surgeons amount to about £120. The classes are open to male and female students.

A syllabus of classes can be obtained on application to the Secretary to the Medical Faculty, St. Mungo's College, 86, Castle Street.

THE ANDERSON COLLEGE OF MEDICINE.—This school provides education in the subjects of the curriculum for both medical and dental students. The school buildings are situated in Dumbarton Road, immediately to the west of the University and Western Infirmary. The hospital practice and clinical lectures are provided in the Western or Royal Infirmary; pathology in the Western or Royal Infirmary; vaccination and dispensary practice in the Western or Royal Infirmary Dispensary. These classes are recognized by all the licensing corporations in the United Kingdom, also by the Universities of London, Durham, Glasgow, and Edinburgh (the latter two under certain conditions stated in the School Calendar).

Fees.—The fees for the lectures and practical work required by ordinary students range between 2 and 6 guineas a class. The Carnegie Trust pays the fees of students at Anderson College on conditions regarding which particulars may be obtained from the Secretary, Carnegie Trust Offices, Edinburgh.

A Calendar will be sent on receipt of a postcard by the Secretary to the Medical Faculty, the Anderson College of Medicine, Glasgow, W.1, who will forward any further information which may be desired.

The Royal Samaritan Hospital for Women, Glasgow, with 160 beds, offers facilities for clinical instruction in the diseases peculiar to women. A university lectureship, the Royal Samaritan Lectureship in gynaecology, is associated with the hospital. The lecturer is Dr. Donald McIntyre. Particulars may be obtained from Mr. T. Mason Macquaker, M.A., B.L., Secretary, 191, West George Street, Glasgow.

St. Andrews and Dundee

The medical departments in these two teaching centres cater specially for students proceeding to the degrees of the University of St. Andrews, but admit other students as well. In the former city the United College provides education in all subjects for the first two years. In Dundee, University College provides for the needs of students from the beginning to the end of the five years' curriculum. Its buildings are modern, and contain fully equipped laboratories. The clinical work of the school is facilitated by various institutions. The class fees are from £6 6s. to £5 12s. 6d. for systematic classes, and from £4 14s. 6d. to £4 4s. for practical classes. The hospital ticket is £1 8s. for three months, £4 4s. a year, or

perpetual, £13 6s. 8d. in one sum. The inclusive or composition fee for the curriculum is £182. In connexion with both institutions there are bursaries and scholarships of considerable value, which are awarded after competitive examination. Information as to these can be obtained from the Secretary of the University of St. Andrews. Information regarding the clinical facilities may be obtained from the Dean of the Medical Faculty, Medical School, Dundee.

Clinical Work

Good opportunities for clinical work are afforded by the Dundee Royal Infirmary, the instruction given thereat being recognized for purposes of graduation by all the Scottish universities, the University of Cambridge, the University of London, the National University of Ireland, and by the Royal Colleges of England and Scotland.

IRELAND

There is a choice of six schools for those pursuing their medical studies in Ireland. For clinical instruction the choice is equally wide and varied, though the hospitals themselves are comparatively small. Some account of the schools follows.

Dublin

School of Physic

This school is in Trinity College, Dublin, and is carried on under the joint auspices of the University of Dublin and of the Royal College of Physicians of Ireland, the King's professors of institutes of medicine (physiology), practice of medicine, materia medica, and midwifery being appointed by the latter. Clinical instruction is given at Sir Patrick Dun's Hospital, and some twelve other metropolitan hospitals and asylums are recognized by the Board of Trinity College. The courses of instruction are open to all medical students, whether they belong to the university or not.

The Schools of Surgery

These are schools carried on in Dublin under the supervision and control of the Council of the Royal College of Surgeons. They are formed of the college's own school, combined with two famous old medical schools—Carmichael and Ledwich; they are attached to the college by charter. The buildings contain spacious dissecting rooms, special pathological, bacteriological, and chemical laboratories. Advantage can be taken of the lectures and instruction afforded by students otherwise unconnected with the college.

Prizes.—Among the prizes annually awarded are: The Barker Anatomical Prize (£26 5s.); the Carmichael Scholarship (£15); the Mayne Scholarship (£8); the Gold Medal in surgery; the Stoney Memorial Gold Medal in anatomy; the H. Macnaughton Jones Gold Medal for midwifery and gynaecology; the Captain Massey Miles Memorial Prize; class prizes, accompanied by silver medals, will also be given in each subject.

A prospectus can be obtained post free on application to the Registrar, Royal College of Surgeons, Dublin.

University College, Dublin

This is one of the constituent colleges of the National University of Ireland. The arrangements for the teaching of medical students from beginning to end of the curriculum are adequate. Applications for information may be addressed to the Secretary and Bursar, University College, Dublin.

Clinical Teaching in Dublin

Two other important obstetric and gynaecological hospitals in Dublin are the Coombe Lying-in Hospital and the National Maternity Hospital. During the year ending December 31st, 1933, the number of cases dealt with in the Coombe Lying-in Hospital were as follows: intern maternity department, total admissions 1,430; intern maternity department, total deliveries 1,279; extern maternity department, total deliveries 1,517; gynaecological department, number of operations 478. Attend-

ance at pre-natal clinic, baby and general dispensaries, 12,000 cases yearly. The practice of these hospitals is attended by large numbers of students, post-graduates, and nurses.

There are numerous well-arranged hospitals in and around the city, and almost all of these are recognized for teaching purposes by the Conjoint Board of Ireland, the University of Dublin, the National University of Ireland, and by like bodies elsewhere in the British Isles. Among them are the Mater Misericordiae Hospital, with 345 beds; Dr. Steevens's Hospital at Kingsbridge, with 150; Meath Hospital and County Dublin Infirmary, with 160; Mercer's Hospital, with 120; the Royal City of Dublin Hospital, with 124; the Adelaide Hospital, with 160; the Royal Victoria Eye and Ear Hospital, with 100 beds; Sir Patrick Dun's Hospital, which has a direct connexion with the School of Physic, and the combined institutions formed by the Hardwicke Fever Hospital, the Richmond Surgical Hospital, and the Whitworth Medical Hospital, with an aggregate of 330 beds.

As for the famous Dublin medical institution known as the Rotunda Hospital, this practically consists of two distinct hospitals, and is believed to be the largest combined maternity and gynaecological hospital in the British Isles. There are pre-natal and paediatric departments as well as a thoroughly equipped pathological laboratory, biochemical laboratory, and x-ray apparatus. It possesses residential quarters for students, and, taken as a whole, offers exceptional opportunities for study both to ordinary students and to medical graduates of any nationality. During the year ending October 31st, 1933, there were 2,650 maternity admissions. Including patients treated in their homes, the Rotunda dealt with 4,782 maternity cases during the year, of which 4,178 were delivered.

The National Maternity Hospital is being entirely rebuilt, and the first section, containing some seventy beds, operating theatres, administration departments, and nurses' home, is now nearing completion, and will be ready for the admission of patients before the end of this year. The fittings and equipment are of the most up-to-date type, and the outstanding feature is an "all-electric" heating, sterilizing, and hot-water system. The second section, to be started early in 1935, will contain a further seventy beds, out-patient, x-ray, and pathological departments, laundry, lecture theatre, etc. There is accommodation for about thirty students and post-graduates, and for a nursing staff of eighty. There are gynaecological, pre-natal, and paediatric departments, both internal and external. During the year 1933 the hospital dealt with 2,185 maternity cases, of which 1,855 were delivered. In the gynaecological department 345 patients were operated on. The attendances at the out-patient department were 7,487. Clinical lectures are given daily.

Belfast

The Medical School is part of the Faculty of Medicine of Queen's University, Belfast, and provides a complete medical curriculum for all purposes. The laboratories in the departments of bacteriology, biochemistry, biology, chemistry, physiology, pathology, public health, anatomy, physics, and materia medica are all excellent, and there is a students' union which gives students the advantages of dining rooms, reading rooms, a library, and various recreation rooms. Women are eligible as students. Clinical instruction is given at the Royal Victoria Hospital, which was rebuilt a few years ago and has 300 beds, and the Mater Infirmorum Hospital, which has 150 beds. Other hospitals open to the students of the university are: the Royal Maternity Hospital; the Ulster Hospital for Women and Children; the Hospital for Sick Children; the Ophthalmic Hospital; the Benn Ulster Eye, Ear and Throat Hospital; the Union Infirmary and Fever Hospital; the Fever Hospital, Purdyburn; the District Lunatic Asylum; the Samaritan Hospital; the Forster Green Hospital for Diseases of the Chest; and the Belfast Hospital for Skin Diseases.

Scholarships.—(1) Eight, of the value of £40 each, are assigned as Entrance Scholarships in the Faculties of Arts, Science, and Medicine, tenable for one year; (2) fourteen Professional Scholarships, value from £15 to £40 each; (3) one Hutchinson Stewart Scholarship, £12, in mental diseases; (4) one Mackay Wilson Travelling Scholarship, £100, awarded triennially (next award, 1936); (5) Isabella Tod Memorial Scholarship, tenable for three years, awarded triennially to a woman student; (6) Magrath Clinical Scholarship, awarded annually, value about £112; (7) two Musgrave Studentships of £200 in physiology and pathology. There is also a post-graduate research fund, open to all graduates of not more than

three years' standing. Gold medals are awarded at the M.D. examination.

Fees.—The cost of the curriculum intended for students proceeding to the degrees of the Queen's University of Belfast is, approximately, £230. This includes examination fees and a perpetual ticket for attendance at the Royal Victoria Hospital or the Mater Infirmorum Hospital, and fees for the special hospitals. The course for the Conjoint Board costs about the same amount.

The Regulations of the Medical Faculty, containing full information, can be obtained on application to the Bursar, Queen's University, Belfast, price 4d.

University College, Cork

This institution, formerly known as Queen's College, Cork, is one of the constituent colleges of the National University. It holds examinations for all the faculties of that university. In addition to continuing the work which it has hitherto performed—namely, that of providing education adapted to the needs of medical students at all stages of their career. Its first aim is to fit students for the degrees of the National University, but students proceeding for the examinations of the Conjoint Board of England, Scotland, or Ireland, the Society of Apothecaries of London or the Apothecaries' Hall of Ireland, or London University, can arrange the courses of lectures which they attend, and the order in which they attend them, to meet the requirements of those bodies. Certificates of attendance at the college courses are also accepted by the University of Cambridge. Clinical instruction is given at the North and South Infirmarys (each 100 beds) and at the Cork Union Hospital (1,200 beds). Students can also attend the Mercy Hospital (130 beds), the County and City of Cork Lying-in Hospital, the Hospital for Diseases of Women and Children, the Fever Hospital, the Ophthalmic and Aural Hospital, and the Eglinton Lunatic Asylum. The session extends from October to June.

There is a Dental School in which the degree of Bachelor of Dental Surgery of the National University of Ireland can be obtained. There is a large well-equipped dental hospital in connexion with the school.

Scholarships.—About £2,500 is available annually for scholarships in the college. Particulars as to each of them can be obtained on application to the Registrar.

Fees.—The fees for the lectures and hospital attendances required by the National University of Ireland course, including examination fees, come to about £175.

Further information can be found in the Calendar, or obtained on application to the Registrar.

University College, Galway

This institution is one of the constituent colleges of the National University of Ireland, and includes Faculties of Art, Science, Law, Celtic, Engineering, Commerce, and Medicine. The college buildings are well lighted and well ventilated, and contain dissecting rooms, an anatomical theatre, and laboratories for the study of physiology, chemistry, physics, and other departments of medical science. For pathology and chemistry new laboratories are now provided. It has good grounds surrounding it, and there are many arrangements, such as a library, a college union, and an athletic union, for the benefit of those belonging to the Medical Faculty, as well as for students in other departments of the college. The clinical teaching, which is recognized as qualifying not only for the degrees of the National University, but for those of the London University and the diplomas of the various colleges in the three kingdoms, is carried on at the Galway Central Hospital and the Galway Tuberculosis Hospital. The Galway Central Hospital is a general hospital, and at the two hospitals students have ample opportunities of studying zymotic and chronic diseases. The Central Hospital has a special ward for diseases of children. Each year the governing body offers about £2,500, and the County Councils of Connaught offer about £3,500, in scholarships. These scholarships are tenable in any faculty. Additional information regarding these scholarships can be obtained on application to the Registrar, and to the Secretaries of the Connaught County Councils.

CLINICAL HOSPITALS IN ENGLAND

Many hospitals in Great Britain and Ireland, though not connected with any medical school, open their doors either to those who have yet to be qualified, to those who are doing post-graduation work, or to both. The facilities they offer for gaining practical clinical experience are very great, and should not be overlooked. Their honorary staffs commonly make a point of giving such instruction as opportunity offers, and at those situated in the larger towns there are often appointments as clinical assistants to be obtained. In addition, they all have to offer, at shorter or longer intervals, appointments for resident medical officers, house-physicians, and house-surgeons. These are usually paid offices, which may be held for periods varying from six months to a year, or even longer. Some of those situated in the great medical centres in the provinces, and in Scotland and Ireland, have already been mentioned in speaking of the medical schools in these localities; but it should be added that there are many other provincial hospitals where admirable work is done, and at which much valuable experience can be gained by both senior and junior students, and by those already qualified. Cases in point are the Royal Infirmary, Bradford; the Royal Sussex County Hospital, Brighton; the Royal United Hospital, Bath; the Worcester General Infirmary; the Kent and Canterbury Hospital; the Derbyshire Royal Infirmary; South Devon and East Cornwall Hospital, Plymouth; the Royal Albert Hospital and Eye Hospital, Devonport; the Royal Devon and Exeter Hospital; the West of England Eye Infirmary, Exeter; the Gloucestershire Royal Infirmary and Eye Institution; the Royal Infirmary, Leicester; the County Hospital, Lincoln; the General Hospital, Northampton; the Norfolk and Norwich Hospital; the General Hospital, Nottingham; the Royal Portsmouth Hospital; the Royal Berks Hospital, Reading; the Royal South Hants and Southampton Hospital; the Staffordshire General Infirmary, Stafford; the North Staffordshire Infirmary at Hartshill; the Royal Hants County Hospital, Winchester; the Wolverhampton and Staffordshire General Hospital; the County Hospital, York; and the Coventry and Warwickshire Hospital.

London Clinical Hospitals

As for the hospitals in the metropolis, so many of these take a share in the giving of clinical instruction that it is worth while to classify them.

Children's Hospitals.—There are at least seven of these, the leader among them being the Hospital for Sick Children, Great Ormond Street, which has 268 beds. There are also the East London Hospital for Children, Shadwell, with 136; the Queen's Hospital for Children, Bethnal Green, with 134; the Victoria Hospital for Children, Chelsea, with 130; the Belgrave Hospital for Children, which has a considerable out-patient department, and in-patient accommodation for 74 children; the Paddington Green Children's Hospital; and the Evelina Hospital for Sick Children, Southwark Bridge Road, with 76 beds. The largest and the oldest of the hospitals for both women and children is the Royal Waterloo Hospital for Children and Women, Waterloo Road, S.E.1.

Hospitals for Women.—Queen Charlotte's Maternity Hospital, Marylebone Road, with 100 beds and a residential college for medical students and practitioners, specializes in the teaching of midwifery. The first section of the new Queen Charlotte's Hospital in Goldhawk Road, Hammersmith, an isolation block of 30 beds for cases of puerperal fever and puerperal pyrexia, was opened in July, 1930. The Bernhard Baron Research Laboratories, immediately adjoining the isolation block, were opened towards the end of 1930, and are fully equipped and staffed. The City of London Maternity Hospital, City Road, with 71 beds, also admits medical students and graduates to its practice. Monthly or

fortnightly residential courses are provided for two medical students at a time, and facilities are offered to post-graduates to see the work of the ante-natal clinics on three mornings weekly. Fees £16 16s. for four weeks, £8 8s. for two weeks (inclusive of board and residence). The Samaritan Hospital for Women, Marylebone Road, admits qualified practitioners as clinical assistants to both the in-patient and out-patient departments; demonstrations are given daily in both departments, the fees—payable in advance—being £3 3s. for three months; full particulars may be obtained from the secretary. In addition may be mentioned the Hospital for Women, Soho Square, whose teaching is confined to post-graduates in limited numbers; the Chelsea Hospital for Women, Arthur Street, Chelsea; and the Elizabeth Garrett Anderson Hospital for Women in Euston Road, the latter being in the nature of a general hospital so far as concerns the class of case treated.

Eye Hospitals.—The largest of these is the Royal London Ophthalmic Hospital (Moorfields), City Road, E.C.1, 152 beds; 3,133 in-patients, 50,074 out-patients in 1931. At this hospital two complete courses of instruction are given during the year—October to February, and March to July—comprising the following subjects: (1) anatomy (including histology and embryology), (2) physiology, (3) optics (including physiological optics), (4) refraction classes, (5) methods of examination and use of the ophthalmoscope, (6) pathology and bacteriology, (7) ophthalmic medicine and surgery, (8) ophthalmoscopic conditions, (9) operative surgery, (10) practical pathology, (11) practical bacteriology, (12) radiology, (13) physiotherapy (including ultra-violet light, diathermy, and ionization), (14) slit-lamp microscopy. A fee of 35 guineas will admit the holder once to all the lectures and classes, except those on physiotherapy and slit-lamp microscopy. The fee of a perpetual ticket to attend the practice of the hospital is £5 5s.; for three or six months, £3 3s.; for two months, £2 2s.; for one month, £1 1s. Registered medical practitioners and medical students are eligible, under certain conditions, for the posts of chief clinical assistant, clinical assistant, and junior assistant. There are also a number of salaried posts, an annual Clinical Research Scholarship of £50, and a biennial Gifford Edmonds Prize of £100. Clinical work begins each morning at 9 and operations at 10 o'clock. The course of instruction is specially adapted to meet the requirements of those reading for the D.O.M.S. and similar diplomas and degrees in ophthalmology. Further particulars may be obtained from the Dean of the Medical School. Other eye hospitals are the Royal Westminster Ophthalmic Hospital, now rebuilt on a new site in Broad Street, High Holborn, and containing 84 beds; the Royal Eye Hospital, Southwark, and the Central London Ophthalmic Hospital, Judd Street, W.C.1, each with about 40 beds; and the Western Ophthalmic Hospital with 18 beds.

Fever Hospitals.—The London County Council has under its control a number of institutions in and around London for the treatment of the more serious zymotic disorders; it makes special arrangements for the instruction of students in this subject, and grants certificates at the end of the courses. The fees for medical undergraduate and post-graduate instruction at the L.C.C. hospitals for infectious diseases and small-pox are as follows: Course in diagnosis and treatment of fevers, three guineas for two months' course. Course in clinical practice and hospital administration (for candidates for the D.P.H.), three and a half guineas for 24 demonstrations and four guineas for thirty demonstrations. Course in diagnosis and treatment of small-pox (in cases in which a fee is payable), one guinea for three demonstrations. Detailed information should be sought from the Medical Officer of Health, Special Hospitals Division, London County Council, County Hall, S.E.1.

Chest Hospitals.—The largest of these is the Brompton Hospital for Consumption, which has 333 beds and a large sanatorium at Frimley with 150 beds. There is also the City of London Hospital for Diseases of the Chest, Victoria Park, with 185 beds, and the Royal Hospital for Diseases of the Chest, City Road, with 85 beds, now amalgamated with the Royal Northern Hospital, Holloway Road.

Nose, Throat, and Ear Hospitals.—The institutions which confine their work to disorders of the throat, nose, and ear all make special arrangements for the benefit of senior and post-graduate students. They are the Metropolitan Ear, Nose, and Throat Hospital, Fitzroy Square; the Royal Ear Hospital, Huntley Street, W.C.1 (now the Ear, Nose and Throat Department of University College Hospital); the Central London Throat Nose and Ear Hospital, Gray's Inn Road; and the Golden Square Throat, Nose and Ear Hospital, near Piccadilly Circus, W.1—the last, which possesses 101 beds, being the largest of the four institutions.

Miscellaneous Special Hospitals.—Among these are the Bethlem Royal Hospital, recently transferred from Kennington to Monks Orchard, Eden Park, Beckenham, Kent, which (like the Maudsley Hospital) confines its work to the treatment of mental diseases, and includes a department for nervous and early mental disorders; the Royal National Orthopaedic Hospital, Great Portland Street; St. Peter's Hospital for Stone and Urinary Diseases, Henrietta Street, Covent Garden; St. Mark's Hospital, City Road, which devotes itself to the treatment of diseases of the rectum, including cancer and fistula; St. Paul's Hospital, Endell Street, Holborn, W.C.2, where continuous post-graduate work in genito-urinary disease is carried on, and two regular post-graduate courses held each year; the National Hospital for Diseases of the Heart in Westmoreland Street, W.1; St. John's Hospital for Diseases of the Skin in Leicester Square; the Hospital for Diseases of the Skin, Stamford Street, Blackfriars; the National Hospital, Queen Square, W.C.1, an institution possessing 200 beds for neurological cases and a world-wide reputation; and the West End Hospital for Nervous Diseases, 73, Welbeck Street, W.1.

Detailed information as to the teaching arrangements of all these institutions may be obtained on application to their secretaries.

Women in Medicine

The regulations of the General Medical Council and of the various universities and colleges set out in previous sections apply to women as to men.

Examinations

Women are admitted to all the medical examinations of the following qualifying bodies: all the universities of Great Britain and Ireland; the Royal College of Physicians of London; the Royal College of Surgeons of England; the Society of Apothecaries of London; and the Conjoint Boards of the Colleges in Scotland and in Ireland. In addition, women are eligible for election as Fellows of the Royal College of Physicians of London, the Royal College of Physicians of Edinburgh, and the British College of Obstetricians and Gynaecologists.

Medical Education

In this country at the present time co-education is the general rule. The schools of the London hospitals have, however, so far shown themselves more conservative in this respect than the rest of the country.

In England the colleges connected with the universities of Birmingham, Bristol, Cardiff, Durham, Leeds, Liverpool, Manchester, Newcastle, and Sheffield admit women students as well as men, whilst in Scotland the universities of Aberdeen, St. Andrews, Edinburgh, and Glasgow also admit women. In Ireland all universities and colleges are open to them.

In London the only schools open to medical women students are the London School of Medicine for Women and, to a modified extent, University College Hospital and King's College Hospital, which last-named has again recently opened its doors to women students. It is felt that such a state of affairs can only be temporary, and hopes are entertained that in the near future the principle of co-education will prevail in the capital.

At the present time it will be seen that the only co-education hospitals in London are University College and King's College. The number of women entrants is restricted, but they are given excellent opportunities whilst students, and also, in fair proportion, are given opportunities of post-graduate experience as residents, house-surgeons, house-physicians, and obstetrical assistants.

Number of Women Students

Returns made to the University Grants Committee show that the total number of full-time women medical and dental students attending university institutions in England, Scotland, and Wales during recent years were:

	1925-26	1927-28	1929-30	1931-32
England	1,059	862	842	910
Wales	30	30	19	40
Scotland	313	254	275	322
Total	1,402	1,146	1,136	1,272

The corresponding total number of full-time male students of medicine, including dentistry, was 9,107 in 1931-2.

The London (Royal Free Hospital) School of Medicine for Women

The London (Royal Free Hospital) School was started for the training of women in medicine in the days before there were any co-education facilities for them, and it still remains by far the largest school for women. In addition to the clinical work at the Royal Free Hospital, which at present has 321 beds, arrangements are made for students of the school to obtain clinical instruction at the National Hospital for Nervous Diseases, Queen Square; the Royal London Ophthalmic Hospital, Moorfields; the Great Ormond Street Hospital for Children; the Elizabeth Garrett Anderson Hospital; the South London Hospital for Women; the Cancer Hospital; and the Central London Ophthalmic Hospital. Its importance for women in medicine can hardly be overestimated, not merely because it was the pioneer which made the way possible, but also because it is still the only general hospital in Britain which offers all its post-graduate appointments, higher and lower, to open competition by women as well as men, thus giving unique opportunity of gaining experience. Not only are all the resident appointments at the Royal Free Hospital, of which there are twenty-seven yearly, eligible for women, but, in addition, higher posts may be obtained in all the various branches of a general hospital, from those of registrar and anaesthetist to those of visiting physician or surgeon and those in charge of special departments. There is a special unit in gynaecology under a woman professor, and entirely staffed by medical women. This policy has so far not been fully adopted in its entirety by any other hospital, and it may be of interest to note in this connexion that the Royal Free Hospital has many women on its general committee and weekly board of management.

Openings for Medical Women

There are at the present time the names of over five thousand medical women on the *Medical Register*. There is an increasing demand by the public for the services of women doctors in all branches of medicine, and statistics show that the proportion of those who make good is as high as, if not somewhat higher than, that of their men colleagues.

Openings at Home

Since the number of men and women qualifying has reached normal standards, medical women find no difficulty in obtaining house appointments in the recognized teaching hospitals and in non-teaching hospitals, hospitals for women and children, sanatoriums, etc. The reorganization of hospitals under local authorities, as an outcome of the new Local Government Act, has resulted in the creation of a number of new resident appointments, senior and junior, intended to be held by medical women. In fact, the supply at the present time does not meet the demand.

General Practice.—There are good openings as assistants or, better still, as assistants with a view to admission as partners in general practice. Medical women also do very well when starting in new districts; and there is considerable scope for them in midwifery work.

Specialist and Consulting Practice.—The number of women doing specialist and consultative practice grows rapidly. There is no branch of medicine in which it is not possible for a patient to consult a medical woman. Women so specializing equip themselves by obtaining the highest essential qualifications, and it is hoped that the time is not far distant when many more women will hold positions on the honorary staffs of all hospitals. Already medical women are on the honorary staff of the Royal Free Hospital, London, and of general hospitals in a number of provincial cities. In London, Edinburgh, Glasgow, Manchester, Bristol, and Brighton there are hospitals staffed entirely by medical women, doing very fine work and meeting a real need, the latest to be opened being the Marie Curie Hospital in London for the treatment of cancer by radium. Research work also provides interesting openings, as, for example, in dealing with the special problems concerning cancer, nutrition, puerperal morbidity and mortality, statistical work, etc., and for some of these research scholarships and grants are available.

Teaching Posts.—Women hold professorships and lectureships at various universities.

Industrial Medicine.—In this branch there is much interesting work available, and it is undergoing considerable development at the present time. Several women already hold such posts.

Administrative Work.—A certain number of these important posts are admirably filled by medical women. At the Ministry of Health the department for maternity and child welfare is staffed by medical women. Medical women also hold high administrative posts under the Home Office, the Board of Education, the Board of Control, etc.

The Public Health Service.—This service provides numerous openings for medical women. It has many departments, and its rapid growth in recent years has provided much interesting work in preventive medicine. Senior departmental posts are frequently held by medical women, and several occupy posts as medical officers of health. For maternity and child welfare work women have been found to be peculiarly suited; but, by a curious economic limitation, married women, who would appear to be the most suitable of all, are, by many public authorities, excluded from service. This exclusion not only prevents married women from taking part in this work, but also prevents many of the best women from specializing in this branch of medicine, as it is obviously uneconomic to specialize in a branch of public service from which one may be excluded in a few years.

Medical Inspection, etc.—Under the Board of Education there are women serving as medical advisers and school medical inspectors. The London County Council and other important councils in the country have medical women on their permanent medical staffs, in both the senior and junior grades. The London County Council has two of its senior medical women appointed to serve as district medical inspectors. In addition, they have a large number of women medical inspectors of school children, and also women are serving as experts in the departments dealing with mental deficiency, tuberculosis, and venereal disease. Some medical women also serve as examiners of the candidates entering the public services, as, for example, the civil service. The services of medical women are extensively enlisted by public authorities in dealing with employees of their own sex. In several instances women serve as assistant medical officers to prisons. The services of medical women are also enlisted as lecturers and examiners on first aid, home nursing, health, and infant care.

Pay and Status

It is interesting to note that medical women, backed by the powerful assistance of the British Medical Association,

have been on the whole successful in resisting the attempt to accept a lower salary for the same work as their men colleagues, thereby not only greatly benefiting themselves, but also maintaining the standard for the whole profession. They realize that ever since the admission of women to the medical profession exactly the same sacrifices for principle have been made by their predecessors as are now demanded from them. With the inauguration of the School Medical Service in 1908, and later when maternity and child welfare posts were created, persistent efforts were made by local authorities to pay their assistant medical officers below the minimum arranged by the representatives of the public authorities and the British Medical Association, and to secure women at a lower rate than men. With rare exceptions these efforts were a failure. Women realize as clearly as men that lowered pay invariably implies a lowered status and prestige, and that the woman who stamps herself as belonging to an inferior grade of doctor cannot complain if she is taken at her own valuation, and that a minimum always tends to become a maximum. Attempts to evade the scale and split the ranks of the profession by offering a post to a man at the agreed rate and a similar post to a woman slightly below that rate are particularly to be deprecated. Where the rule of equal pay for equal work is violated there is no limit to the extent to which women may be exploited.

Openings Abroad

Colonial Office.—To those to whom oversea service appeals it offers the possibility of useful, interesting, and adequately paid work. At present there are posts for women in Malaya, and East and West Africa. The work is almost entirely hospital and maternity and child welfare work; there have been one or two specialist appointments, such as bacteriologists, and more may follow. Women have, so far, only been appointed to the lower-grade posts, but their pay is the same as that of the men in similar grades. When placed on the permanent staff they are eligible for pension.

Egypt.—Appointments in the Kitchener Memorial Hospital, Cairo, which forms part of the Clinical Faculty of the University of Cairo, are held by women. Appointments in certain dispensaries are open to medical women. There are also posts held under the education authority, chiefly school medical inspection.

India.—See note on the Women's Medical Service for India on page 428.

Mission Field.—Missionary societies offer employment to medical women, chiefly in India, China, and the Near East.

Public Activities

Medical women are frequently appointed to serve on Royal Commissions and Government Committees dealing with medical subjects, and are also requested by them to give evidence of an expert medical nature.

Medical women have always shown considerable interest in medico-political affairs, and take an active part in the work of the British Medical Association, and with the various other societies dealing with medicine as it affects the community in general. With this end in view they also have a Medical Women's Federation, which enables them to voice a collective expression of opinion. This might otherwise be difficult to ascertain, as women are so widely scattered, both as regards their geographical distribution and their varied activities. This collective opinion of medical women has been found of great assistance by the British Medical Association and other allied societies with which it works in cordial co-operation and by whom it is frequently approached, both for information and also as a convenient means of approaching medical women as a whole.

It may be added, with regard to contributions to medical literature, that this is a branch of work in which women are more and more taking their share, and scientific and other works are frequently published by them.

WOMEN'S MEDICAL SERVICE FOR INDIA

Among careers open to medical women abroad the Women's Medical Service for India deserves honourable mention. This Service is open to fully qualified medical women of British or Indian nationality, and with the present amount of Government subsidy the number of medical officers is limited to 44.

Medical women proceeding to India to join the Women's Medical Service receive a sufficient sum for a first-class passage to India. On landing they are posted to one of the larger women's hospitals to gain Indian experience and to learn the language. For a further period they are appointed to act temporarily for medical women on furlough. They are then definitely appointed to the charge of hospitals. Private practice is allowed, provided it does not interfere with official duties. The only exception is in administrative or educational posts, when an allowance in lieu of practice is given. The amount obtained from practice varies according to the station, but in most cases it forms a fair addition to the salary, varying from £150 to £1,000 a year.

Excellent opportunities for surgery—especially gynaecological—are found in the Women's Medical Service. To those who are not keen surgeons opportunities are likely to open in the future in connexion with maternity and child welfare. Rates of pay are as follows:

Years of Service	Oversea Allowance per Mensem	Salary per Mensem	English Equivalent* per Annum
1 to 3	Rs. 100	Rs. 450	£440
4 to 6	Rs. 100	Rs. 500	£480
7 to 9	Rs. 100	Rs. 550	£520
10 to 12	Rs. 100	Rs. 600	£550
13 to 15	Rs. 150	Rs. 650	£600
16 to 18	Rs. 150	Rs. 700	£640
19 to 21	Rs. 150	Rs. 750	£680
22 to 24	Rs. 150	Rs. 800	£720
Over 24	Rs. 150	Rs. 850	£760

* At rupee value 1s. 4d.

Furnished quarters are provided, representing an additional Rs. 150 per mensem.

The cost of living in India is much higher than formerly, but it should be possible for a medical woman (with house provided) to meet actual household expenses for about Rs. 300 per mensem, leaving the remainder of her salary for dress and personal expenses. To this must be added the necessary saving to meet additional expenses for furlough and leave spent in the hills.

Leave on average pay is earned at the rate of two-elevenths of the period spent on duty.

Study leave is granted to the extent of twelve months in the total service, and will not be granted more than twice in the course of an officer's service. During study leave an officer draws half average pay, with a study allowance at the rate of 12s. a day during the course of study. Officers of European domicile are entitled to four free return first-class passages from a port in India to a port outside India in their whole service. The first passage is not granted until after the expiry of four years' approved service, and thereafter passages may be granted at intervals of not less than four years. There is a Provident Fund to which members of the Service contribute 10 per cent. of their pay. The Service contributes another 10 per cent., which accumulates at interest and is repaid on retirement.

Admission to the Service is made by selection in India and England, preference being given to those with Indian experience. Vacancies are few. Candidates in the United Kingdom should apply to the honorary secretary, United Kingdom Branch of the Countess of Dufferin's Fund, c.o. Major-General Sir John Megaw, India Office, Whitehall, London. Candidates in India should apply to the Chief Medical Officer, Women's Medical Service, Countess of Dufferin's Fund, Simla and Delhi.

Post-Graduate Study

Post-graduate students may be divided into general practitioners desirous of refresher courses, usually covering a wide field within a relatively short period of time, to bring their knowledge up to date; those who wish for instruction in special subjects with a view to obtaining one of the special diplomas or of preparing for some higher examination, perhaps with a view to promotion in one or other of the medical services, or, if already general practitioners, of adding some form of specialism to their work; and visitors, whether from the overseas Empire or from foreign countries, who wish to pursue intensive studies in special subjects or to familiarize themselves with the methods of practice in Great Britain. Further mention may be made of medical members of the Defence Services who, for reasons similar to these, constitute an important section of post-graduate students.

It is clear that London, with the large and varied amount of material available, and with its wealth of professional skill and teaching power, offers ample opportunity for the supply of all these needs if suitable concentration and organization of effort can be brought about and established. So far, however, no definite post-graduate school of the general character and scope required has yet begun to function; though, as described below, steps have now been taken which should render this statement inaccurate by the time our next Educational Number is published. Such teaching centres as at present exist are widely scattered, and their efforts are limited and largely unsystematized. Two hospitals—the West London Hospital at Hammersmith, and the Prince of Wales's General Hospital at Tottenham—have for many years had post-graduate colleges attached to them. Their efforts are valuable and praiseworthy, but they can cater only for a limited number of general practitioners, and these largely drawn from those whose practices are within a relatively short distance of the schools. The general practitioner may also perhaps find a refresher course at the hospital at which he was trained held during a vacation, and similar short courses are organized from time to time at one or other of the London hospitals. The Fellowship of Medicine, too, arranges definite courses of study at individual hospitals; and at its office—generously placed at its disposal by the Royal Society of Medicine at 1, Wimpole Street, W.1—a list of hospitals, special and general, to which medical graduates may resort, with or without fee, is kept, and the names of the teachers at each hospital are available. Occasional courses of a more special character may thus be discovered.

There has recently been a steady increase in the demand for post-graduate instruction in the psychological aspects of medicine, and this will probably continue owing to the passage of the Mental Treatment Act and other causes. Systematic attempts to provide this are being made by at least three bodies. There are courses for the diploma in psychological medicine held at the Maudsley Hospital. Courses in mental deficiency are held once or twice yearly, organized by the Central Association for Mental Welfare in conjunction with the University of London. The Institute of Medical Psychology (formerly the Tavistock Clinic), in addition to an introductory course of about a month's duration in October, and a three months' course in the summer term, has two main courses in psychotherapeutic theory and method covering one year's work: these are open to a limited number of practitioners only—one is arranged for those who can give only three hours twice a week for this purpose; the other is for those who wish to specialize and are prepared to give a minimum of twelve hours (on three days) in the week. The Institute now has admir-

able premises at Malet Place, W.C., and such systematic teaching as that indicated has been more fully and effectively developed there.

Over and above such specialized or occasional teaching, it is possible to obtain under one roof instruction in all branches of preventive and of tropical medicine at the London School of Hygiene and Tropical Medicine, at the corner of Keppel Street and Gower Street. This institution was opened in July, 1929, and has established itself as a most valuable school of the University of London in the faculties of medicine and science. Here are university chairs in public health, bacteriology, biochemistry, epidemiology, helminthology, medical protozoology, medical entomology, and medical industrial psychology.

The principal courses of study are for the university diplomas in public health, in bacteriology, in industrial psychology, and for the diploma in tropical medicine and hygiene (Eng.) of the Conjoint Board of the Royal Colleges. Special courses of instruction are also arranged in other subjects. The course of study for the diploma in public health includes not only lectures and demonstrations on the theory and practice of public health administration and the principles of sanitary law, but also a large number of visits to places of public health interest, including centres of industrial welfare. The course of study includes also sanitary engineering, practical work under a medical officer of health, instruction in infectious disease and hospital management, and two important studies which have recently been established—namely, physiology as applied to hygiene and industry, and medical industrial psychology. The course of study for the diploma in tropical medicine and hygiene can be taken in two parts, Section A being a three months' course of laboratory and clinical instruction and Section B a two months' course in tropical hygiene, and there are special arrangements for short periods of instruction for students unable to attend the whole course. Facilities for clinical work are afforded at the Hospital for Tropical Diseases, close by. At the Seamen's Hospital, too, in co-operation with the London School of Hygiene and Tropical Medicine, post-graduate courses for ship surgeons are now held systematically. With the incorporation in this school of the Ross Institute the studies in tropical hygiene have now received a new impetus and direction.

The shortcomings of London as a post-graduate medical centre have been recognized for a long time, and it is gratifying to know that practical steps have now been taken to remedy the several disabilities that have been mentioned, and to establish under the auspices of the University of London and the London County Council, with governmental financial aid, a real post-graduate hospital and medical college which will be worthy of the metropolis of the Empire. As long ago as 1921 a committee on post-graduate medical education was set up under the chairmanship of the Earl of Athlone. The establishment of "a school attached to a hospital centrally situated in London devoted solely to post-graduate medical education as a school of the University" was the chief recommendation that resulted. In 1925 a second committee was appointed "to draw up a practical scheme of post-graduate medical education centred in London." The scheme finally suggested was to use one of the Poor Law hospitals transferred to the London County Council under the Local Government Act, 1929, as a British Post-Graduate Hospital, and to establish a fully equipped medical school in connexion therewith. The hospital chosen for the purpose is the Hammernsmith Hospital at Shepherd's Bush, which is a modern institution with, at present, 400 beds, on a site of sufficient acreage to allow of extension and of the creation of the necessary college buildings. On this site the British Post-Graduate Medical

School is now in course of erection. A third committee, known as the Provisional Organization Committee, with Lord Chelmsford as chairman, reported in 1931 upon "(1) the action requisite to lead up to the planning and construction of the medical school, and (2) the form of government appropriate to the hospital and medical school with special reference to the position of the London County Council as the local authority responsible for the hospital, and to the position of the University of London in relation to the medical school." This has resulted in the approval by the King in Council of a Royal Charter constituting the Governing Body of the school and defining the functions of the governors. The Governing Body consists of representatives of various Government Departments, of the London County Council, of the University of London, and of the Royal Colleges of Physicians and Surgeons, the Society of Apothecaries, the Royal Society of Medicine, and the British Medical Association. The late Lord Chelmsford was its first chairman, and he has been succeeded by Sir Austen Chamberlain, K.G. Although the economic situation delayed developments, both the Government and the London County Council are now providing sufficient, though reduced, financial assistance. The foundation stone of the Medical School buildings was laid in July, 1933, by Mr. Neville Chamberlain, the Chancellor of the Exchequer. These buildings, with their main equipment, will, it is expected, be completed by the end of the present year. It is possible that the school may begin its actual teaching work by March 1st next. Dr. M. H. MacKeith, Dean of the Medical School of the University of Oxford, has been appointed its dean, and appointments to the professorships of medicine, of surgery, of obstetrics and gynaecology, and of pathology have also been made. Other appointments to the staff may be expected quite shortly. It is even hoped that before long the enlargement of the hospital to one of 600 beds, as contemplated by the Chelmsford Committee, may be undertaken by the London County Council. Arrangements will probably be made, also in accordance with the suggestions of that Committee, to associate the work of the Post-Graduate School and Hospital with that of some other hospitals of a special character—for example, in the spheres of psychological medicine, of neurology, and of diseases in children. No syllabus or prospectus has yet been issued, but it is understood that all classes of post-graduate students mentioned in the first paragraph of this article will be catered for. There may well be fortnightly "refresher" courses for general practitioners continuing during eight or nine months of the year, and longer courses of three months' duration for other students. Care is to be taken that no class is too large for its individual members to take full advantage of the clinical instruction provided, and it may be found possible to afford opportunity for the holding of house appointments or of clinical assistantships by a certain number of practitioners who, on the completion of their course, wish in this way to prolong their experience and association with the work of the hospital. London will thus, before long, become, as it should be, a world centre of post-graduate medical training.

In the provinces the Universities of Oxford, Cambridge, Birmingham, Bristol, Liverpool, Manchester, and Sheffield have organized courses of post-graduate work and instruction. Liverpool University has established a regular course for ship surgeons on similar lines to that already mentioned in London. Edinburgh receives graduates from many schools in the Dominions as well as in this country. In Glasgow and in Aberdeen courses are available, and, in relation with the University of St. Andrews, courses are given by the James Mackenzie Institute for Clinical Research. At many of these centres the teaching is pro-

vided by whole-time intensive courses, by part-time courses, and by means of clinical assistantships. The Joint Tuberculosis Council has provided nomadic courses in its own special subject, and a considerable number of the Divisions of the British Medical Association are now organizing post-graduate courses in their own locality.

Short particulars about the facilities for post-graduation study at present obtainable in Great Britain and Ireland are given in Section VII of the *Handbook for Recently Qualified Practitioners*, published by the British Medical Association (price 3s. 6d.).

Fellowship of Medicine and Post-Graduate Medical Association

The Fellowship of Medicine arranges regular courses in general medicine and surgery, including special departments, each lasting from one to four weeks. Courses in diseases of the chest, children, ante-natal, heart, nervous system; dermatology; gynaecology and obstetrics; proctology; orthopaedics; fractures; psychological medicine; physical therapy; rheumatism; urology; practical anaesthetic tuition; and in venereal diseases are given from time to time at the special hospitals in association with the Fellowship of Medicine. Evening clinical and pathological courses for the M.R.C.P. (three times a year) and F.R.C.S. (Final) (twice a year) are arranged also. Week-end and evening courses are arranged in many subjects. A panel of teachers is always available for clinical teaching, by arrangement with the Fellowship. Lectures and demonstrations are arranged periodically. The office of the Fellowship is, by kind permission of the Royal Society of Medicine, at No. 1, Wimpole Street, W.1 (telephone, Langham 4266). The secretary is in attendance daily from 10 a.m. to 6 p.m. (Saturday 10 a.m. to 1 p.m.). The annual subscription for membership of the Fellowship of Medicine and Post-Graduate Medical Association is £1 1s., which includes the *Post-Graduate Medical Journal*, published monthly. Courses, lectures, and demonstrations are open only to members.

Post-Graduate School of Radiotherapy

The working scheme announced in our issue of June 28th, 1930 (p. 1185), between the London Radium Institute in Riding House Street and the Mount Vernon Hospital at Northwood, for the establishment under joint control of a Post-Graduate School of Radiotherapy, continues in operation. The Dean (Sir Cuthbert Wallace) will be pleased to see prospective students by appointment. Applications for information may be addressed to the Secretary (Mr. T. A. Garner) at the School, Riding House Street, London, W.1.

West London Post-Graduate College

The work of this institution is carried on at the West London Hospital, the first in London to devote its clinical material solely to the instruction of qualified medical men. The college started in 1895; it is provided with lecture, reading, writing, and class rooms, and accommodation of all sorts for the convenience of post-graduate students. The work of the college is eminently suitable for men in general practice and officers in the Services who wish to revive their general clinical knowledge.

As for ward work, the students accompany the senior staff on their visits to the wards. The out-patient department is large, and affords ample facilities for post-graduates to see and examine patients. There are the usual special departments. Post-graduates are appointed to act as clinical assistants for three or six months, no charge being made. A special clinic for the treatment of venereal diseases (male and female) is held all day. Graduates are admitted to the work of the clinic free, and certificates of satisfactory attendance and work are given.

Operations take place at 2 p.m. daily, the surgeons often availing themselves of the assistance of the gradu-

ates, and in any case making arrangements so that they can readily see what is going on. The pathological laboratory is in charge of a pathologist, who attends every day. Demonstrations are given in the morning by the assistant physicians and surgeons, and by the medical and surgical registrars.

The certificates of the school are recognized by the Admiralty, the War Office, the Colonial Office, the India Office, the University of London (for higher degrees), and the Conjoint Board. The general course is recognized as being suitable for practitioners taking a course of study under the Ministry of Health "grant-aided scheme for post-graduate study by insurance practitioners in rural areas." A prospectus can be obtained on application to the Dean.

Fees.—Hospital practice, including all ordinary demonstrations and lectures, £2 2s. for one week, £6 6s. for one month, £9 9s. for two months, £12 12s. for three months. Instruction in the administration of anaesthetics is given at the rate of £3 3s. a month.

North-East London Post-Graduate College

The headquarters of this post-graduate school are situated at the Prince of Wales's General Hospital, Tottenham; N.15, in the midst of this densely populated North London district. It contains 238 beds, and is within a few minutes' walk of South Tottenham Station on the London Midland and Scottish Railway, and Seven Sisters and Tottenham Hale Stations on the London and North-Eastern Railway. It is readily accessible by electric tram from Manor House and Hackney, and from Dalston, Edmonton, and other parts of North London. The North Middlesex Hospital, Edmonton, N.18; with upwards of 1,000 beds, has, under a recent arrangement, taken part in the clinical teaching.

The college is in association with the Fellowship of Medicine and Post-Graduate Medical Association, and is recognized by the Admiralty and India Office for the purpose of study leave, and by the University of London as a place for advanced study for the M.D. and M.S. degrees; the course of practical teaching of bacteriology is approved by the University of Cambridge for its Diploma in Public Health, and there are ample arrangements for the convenience of men who are thus working, or who, being in active practice, are desirous of getting themselves into touch with modern methods. The hospital as a whole affords excellent facilities for qualified medical practitioners who wish to take part for a time in active general hospital work, or to obtain special instruction in the several branches of medicine and surgery, since it is open to them to study diseases of the eye, ear, throat, nose, skin, fevers, children's diseases, psychological medicine, dental surgery, radiography, the application of electricity in disease, and the administration of anaesthetics. Throughout the sessions, into which the year's work is divided, clinics, lectures, and demonstrations are given by members of the teaching staff. Operations are performed every afternoon of the week except Saturday. Special vacation or intensive courses are held at intervals throughout the year, each lasting two weeks, clinical instruction being arranged for each hour of each day. The winter session will be opened about the middle of September as regards clinical teaching.

Fees.—For the hospital practice in general medicine or surgery the fee is 5 guineas for three months or 2 guineas for one month. Provided there is accommodation in the special departments, the fees are: eye department 3 guineas; gynaecological department 5 guineas; ear, nose, and throat department 5 guineas for three months. All departments—the fee is 3 guineas for one month, 6 guineas for three months, 10 guineas for a year, and 15 guineas for a perpetual ticket.

Additional information can be obtained from the Dean of the Post-Graduate College, at the Prince of Wales's Hospital.

West End Hospital for Nervous Diseases

The post-graduate facilities of this hospital include: (1) courses of one month's duration—one hour or so daily—in common diseases of the nervous system, a number of short concentrated courses on particular subjects, and special concentrated courses for general practitioners lasting one week: the next course will be given from October

29th to November 3rd as advertised by the Fellowship of Medicine; (2) courses of instruction in psychological medicine as applied to children, in connexion with the Hospital's Child Guidance Unit; (3) a comprehensive course of instruction in speech therapy (which is acceptable to the Board of Education).

The clinical and teaching facilities of the hospital fulfil the requirements of the Examining Bodies for the Diploma in Psychological Medicine, and for the London University M.D. degree, Part III. Appointments as honorary clinical assistants (six months) and honorary clinical psychologists (twelve months) are made as required, and are open to candidates desiring facilities for the study of neurological and psychological conditions. The annual out-patient attendance is between 38,000 to 40,000 at the out-patient department, Welbeck Street, W.1. The in-patient department, Outer Circle, Gloucester Gate, Regent's Park, provides seventy-six beds, including twenty-five cots for children, and is fully equipped with a pathological laboratory and other special departments.

Manchester Post-Graduate Facilities

Courses in preparation for the diplomas in psychological medicine, in public health, bacteriology, pathology, and veterinary State medicine are arranged. There are facilities also for obtaining a certificate in venereal diseases. A limited number of clinical assistantships at the discretion of the hospitals are offered in the medical, surgical, and special departments of the Manchester Royal Infirmary, the Ancoats Hospital, and certain special hospitals for one, two, or three months, or longer. A clinical assistantship at the Radium Institute for three months is offered. Clinical teaching for post-graduates is given each Thursday during university terms by the honorary staff at Ancoats Hospital; no fee charged.

Post-Graduate Courses at Bristol

The University of Bristol provides courses of post-graduate study for practitioners. Details of set courses at the Royal Infirmary and General Hospital are announced locally. In addition, practitioners may become clinical assistants in medicine, surgery, or special subjects for periods of a month or more.

Daily Post-Graduate Study.—For those who are able to devote several hours each day to hospital practice the university offers special facilities for post-graduate work. Qualified medical practitioners may be appointed as clinical assistants for a period of one or more months. They may act as assistants, if times permit, in more than one department and in any of the hospitals during their period of study. They will be entitled to the use of the clinical laboratories and medical library, and have the right to attend in all departments, including operations, post-graduate and ordinary clinical demonstrations, and post-mortem examinations.

All inquiries and applications for admission should be addressed to the Director of Post-Graduate Studies (Clinical Section), Department of Medicine, University of Bristol.

Post-Graduate Courses at Newcastle

For the year 1934-5 the following post-graduate courses have been arranged by the College of Medicine, Newcastle-on-Tyne (University of Durham):

1 General courses in clinical medicine, surgery, and pathology at the Royal Victoria Infirmary, meeting once weekly for ten weeks. One course will be held from October to December, and one from April to June.

2 Special courses of clinical instruction meeting once weekly for ten weeks in the following subjects: gynaecology, diseases of the eye, diseases of the throat, nose, and ear, diseases of the skin, venereal diseases, neurology. Special courses in midwifery will be held at the Princess Mary Maternity Hospital.

3. An intensive course of fourteen days' duration in the summer vacation, 1935.

4. In addition to the regular post-graduate courses, practitioners may attend the ordinary medical and surgical practice of the Royal Victoria Infirmary, and also at the Princess Mary Maternity Hospital, for specified periods.

5. Classes are held at the Newcastle General Hospital for clinical instruction in medicine and surgery, or lecture-demonstrations, every Sunday morning during term. There is no fee, and all medical practitioners are invited to attend.

6. General and special courses in dental surgery are also provided in the Dental Department.

Edinburgh Post-Graduate Courses

In connexion with the University and Royal Colleges post-graduate courses are arranged every year, from about the middle of July to about the middle of September, comprising: (a) a course in obstetrics and gynaecology, held from July 16th to August 4th; (b) a course in child life and health extending from August 6th to 11th; (c) a general practitioner course; (d) a general surgical course. Courses (c) and (d) extend for four weeks from August 13th to September 8th. Similar courses are held each year.

The course in obstetrics and gynaecology includes instruction in clinical midwifery and clinical gynaecology, obstetrics and gynaecological pathology, ante-natal and post-natal clinics, etc.

The general practitioners' course includes lecture-demonstrations, and, where possible, practical instruction on medical anatomy, medical sideroom work, examination of the blood, x-ray and electrical therapy, morbid anatomy, and post-mortem examination; clinical instruction in medicine, surgery, gynaecology, child life and health, diseases of the skin, and infectious diseases; and special instruction in the diseases and methods of examination of the nervous, circulatory, respiratory, alimentary, and renal systems, and in diseases of the ductless glands. The general surgical course includes lecture-demonstrations on surgical anatomy, surgical pathology, and surgical x-ray diagnosis; clinical instruction in surgery at the Royal Infirmary and Royal Hospital for Sick Children; clinical instruction in venereal diseases; surgical out-patients, surgical and gynaecological operations, and special instruction in abdominal and genito-urinary and other branches of surgery.

A series of clinical discussions, open to all graduates, is arranged on subjects of general interest. Among the special courses also arranged at various times of the year are: examination of the blood, diseases of the ear, nose, and throat, ophthalmoscopy, venereal diseases, x-ray physics and electrotechnics, tuberculosis, ultra-violet radiations and their uses, the interpretation and significance of modern diagnostic methods, surgical pathology, clinical surgery, clinical medicine, urological surgery and treatment of fractures, neurological surgery, disorders of speech and voice, orthopaedic surgery, child life and health, endocrinology, diseases of the nervous system, urology.

Particulars regarding the courses, dates of commencing, fees, etc., may be had on application to the Honorary Secretary, Post-Graduate Courses in Medicine, University New Buildings, Edinburgh.

Post-Graduate Medical Teaching in Glasgow

Organized post-graduate medical teaching is available in Glasgow under the auspices of the Post-Graduate Medical Association. This association represents practically all the teaching institutions in Glasgow and the various teachers giving post-graduate instruction, and its business is managed by a board elected periodically by them. The chairman of the board is Professor Sir Robert Muir. During the winter months special courses in various subjects are conducted and a number of post-graduate lectures given. From November till May there is a series of weekly demonstrations specially designed for local practitioners. Clinical courses are carried out during the summer months, and arrangements have also been made whereby a limited number of graduates may become attached to wards or out-patient departments nominally as clinical assistants for definite periods throughout the year. As such they work under the direct supervision of the physician or surgeon in charge, and carry out such detailed investigations as directed.

A general medical and surgical course is held each year during the last two weeks of August and the first two weeks of September, which is arranged to include most

of the subjects of interest to the general practitioner. This year the course is being conducted from August 20th to September 14th. The forenoons are occupied with general medicine and surgical diagnosis and minor surgery, in the Royal Infirmary and in the Victoria Infirmary. In the afternoons special subjects are dealt with in the special hospitals and in the special departments of the general hospitals, two subjects being considered most afternoons.

Further information may be had on application to Dr. James Carslaw, Secretary, Post-Graduate Medical Association, 9, Woodside Terrace, Glasgow, C.3.

Tropical Medicine

There are large and important Schools of Tropical Medicine in London and Liverpool, and the Colonial Office expects all nominees for the Colonial Medical Service to pass through one or other of the two schools mentioned before their appointments are confirmed, and commercial firms engaged in tropical enterprise commonly demand from medical applicants for employment corresponding evidence of special knowledge. Information with regard to these schools and diplomas and degrees is given in the paragraphs printed below. The University of London alone gives a degree (M.D.) in Tropical Medicine, and this, being an "internal degree," can only be taken by students who are medical graduates of that university. Diplomas in Tropical Medicine or Hygiene are granted by the universities of Edinburgh and Liverpool, and by the Conjoint Board of the Royal College of Physicians of London and the Royal College of Surgeons of England.

Diplomas and Degrees

LONDON UNIVERSITY.—Tropical medicine is one of the six branches in which the M.D. degree may be obtained. Candidates must normally have taken the M.B., B.S. degree not less than two years previously and must subsequently have attended a course of one academic year in tropical medicine at an approved school, or must have practised for two years in a region where tropical diseases prevail. In exceptional circumstances candidates may enter for the M.D. examination one year after taking the M.B., B.S. degree.

THE CONJOINT BOARD IN ENGLAND.—This body grants a diploma in tropical medicine and hygiene to candidates after an examination held in the months of January, April, and July. New regulations are in force, and twenty-one days' notice in writing instead of fourteen days is now required of candidates for all examinations. Section A comprises clinical tropical medicine and surgery; applied pathology, zoology, and elementary bacteriology. Section B, tropical hygiene, including epidemiology, medical zoology, and bacteriology in relation to hygiene. Candidates may enter for either or both sections provided that A is taken before B. The examination fee is nine guineas. Candidates must possess a qualification in medicine, surgery, and midwifery recognized by the Board, and produce evidence of attendance, subsequent to qualification, at courses of instruction as laid down in the regulations. The hospitals and laboratories recognized for this diploma are the London School of Hygiene and Tropical Medicine, the Royal Army Medical College, the Liverpool School of Tropical Medicine, and the School of Tropical Medicine, Calcutta. Particulars and conditions of admission to these examinations, fees, etc., may be obtained from the Secretary, Examination Hall, Queen Square, London, W.C.1.

UNIVERSITY OF LIVERPOOL.—A diploma in tropical medicine is given by this university to candidates possessing a recognized medical qualification who have attended the courses provided by the Liverpool School of Tropical Medicine and who have passed the examination held twice yearly by the university examiners. The subjects

of examination are: (a) parasitology; (b) entomology; (c) tropical medicine, including aetiology, symptoms, pathology, diagnosis, and treatment of tropical diseases. Fee for the course, £21. A diploma in tropical hygiene (D.T.H.), open to the holders of the D.T.M., has also been established. The subjects of examination are tropical hygiene (including sanitary engineering, vital statistics and epidemiology, and applied parasitology and entomology); practical sanitation, bacteriology, chemistry (including meteorology and climatology). Fee for the course, £12 16s. Further information can be obtained from the Dean of the Faculty of Medicine, University of Liverpool.

UNIVERSITY OF EDINBURGH.—Candidates for the diploma in tropical medicine and hygiene granted by the University of Edinburgh must be graduates in medicine and surgery of that university, or hold corresponding degrees or qualifications registrable with the General Medical Council of Great Britain, or of such other universities or medical schools as may be recognized for the purpose by the University Court. The course of instruction, which commences in October, extends over two terms. The examinations (Part I and Part II) are written, oral, and practical, and are held at the end of the courses. Candidates, on the first occasion of presenting themselves for examination in either part, are required to appear for all the subjects of that part. Those who fail to pass the entire examination in either part within a period of twelve months after first appearance are required to reappear for all the subjects. The university is included in the list of institutions whose courses of instruction in tropical medicine may be taken by officers on appointment to the Colonial Medical Services or during study leave. Full particulars can be obtained from the Dean of the Faculty of Medicine, Edinburgh.

SCHOOLS

London School of Hygiene and Tropical Medicine (University of London)

(Incorporating the Ross Institute)

The courses of study in all branches of the work of the School will recommence in the autumn in the premises in Keppel Street (Gower Street), the gift of the Rockefeller Foundation, which has excellent laboratories and research rooms, a fine lecture theatre and class rooms, library, and museum.

The course of instruction for the diploma of the Conjoint Board in tropical medicine and hygiene is divided into two parts: Section A, a three-months' course of clinical and laboratory instruction, and Section B, a two-months' course in tropical hygiene. Each section has been so designed that it can be taken independently of the other, and the examinations by the Conjoint Board will follow closely upon the end of the corresponding course of study. This revised course is recognized by the University of London as a course for associate students.

The dates of the courses for the session 1934-5 are as follows:

Section A (Clinical and Laboratory Instruction).—A three-months' course, October 1st to December 21st, 1934; January 7th to March 30th, 1935; April 8th to June 28th, 1935.

Section B (Tropical Hygiene).—A two-months' course, January 21st to March 22nd, 1935; April 23rd to June 21st, 1935.

The course of instruction under Section A includes clinical tropical medicine, applied pathology, medical zoology, and elementary bacteriology. Section B comprises instruction in tropical hygiene, including, in relation to hygiene, bacteriology, medical zoology, anthropology, and vital and medical statistics.

There are special arrangements for short periods of instruction and also for students who are unable to attend at the beginning of a course.

The instruction in the division of clinical tropical medicine is given by the medical staff of the Hospital for

Tropical Diseases and by visiting lecturers. In this way the resources of the hospitals of the Seamen's Hospital Society at Endsleigh Gardens, at the Albert Docks, and elsewhere, become available for the clinical instruction of the students at the school.

The course of study for the diploma in public health will commence on October 1st, and will extend over a period of nine months' whole-time study. It is arranged in compliance with the requirements of the General Medical Council, and students taking the course will be able, should they so desire, to proceed to the academic diploma in public health of London University. The curriculum has been planned on very practical lines, and includes, in addition to work with medical officers of health in two selected areas, a large number of visits to places of public health interest. A series of special lectures is given by eminent authorities, and are open to members of the medical profession as well as to students of the school. The London County Council, the City of London, and various other bodies have placed their resources at the disposal of the School for teaching purposes.

The course of study for the University of London diploma in bacteriology covers a period of one academic year beginning in October, and special three-monthly courses will be given in epidemiology and vital statistics.

Special courses of study are arranged for the academic diploma in psychology (industrial) of the University of London.

Inquiries with regard to all the above-mentioned courses should be addressed to the Secretary, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1.

University of Edinburgh

A course of instruction for the diploma comprising a primary and a secondary course is given during the autumn and spring terms (October to March), and includes tropical hygiene, bacteriology, entomology, and parasitology, diseases of tropical climates (systematic and clinical), tuberculosis, and venereal diseases. The university is included in the list of institutions whose courses of instruction in tropical medicine may be taken by officers on appointment to the Colonial Medical Services or during study leave. Full particulars can be obtained from the Dean of the Faculty of Medicine.

Liverpool School of Tropical Medicine

This school is affiliated with the University of Liverpool. The university grants diplomas in tropical medicine (D.T.M.) and in tropical hygiene (D.T.H.).

Two full courses of instruction, each lasting about eleven weeks, are given every year for the D.T.M., commencing respectively October 1st, 1934, and January 3rd, 1935, and two courses for the D.T.H., beginning on January 10th and April 25th, 1935. The D.T.H. can only be taken by those who have obtained the D.T.M. Students who do not desire to take the diploma examinations held by the university at the end of each term are given a certificate if attendance has been satisfactory.

Fees.—(1) For the D.T.M. course, 20 guineas; for the D.T.H. course, 10 guineas. (2) For the diploma examinations, 5 guineas. An extra charge of one guinea is made for the use of a microscope if required.

The laboratories of the school adjoin the university and the tropical ward of the Royal Infirmary. The dimensions of the building are 162 feet in maximum length by 84 feet in width. In addition to the basement, in which are accommodated the photographic department and large storage rooms, there are four floors. The ground floor has: (1) lecture theatre, with accommodation for about seventy students; (2) library; (3) a spacious museum with preparation room adjoining. The first floor has twelve rooms, in which are housed the departments of tropical medicine and entomology. The second floor has the main class laboratory, 69 feet by 58 feet, excellently lighted; and three other rooms, devoted to the department of parasitology. The third floor has a large research laboratory and two research rooms. On the roof is an insectarium, a mosquito-proof house, and other accommodation.

Since its foundation the school has dispatched to the Tropics thirty-two scientific expeditions, many of the workers having been taken from among its students. The work done by the staff has been published in twenty-four special memoirs; in the *Annals of Tropical Medicine and Parasitology*, issued by the school; and in numerous articles in the scientific press.

The school also has a laboratory in the Tropics; the Sir Alfred Lewis Jones Tropical Laboratory in Sierra Leone, which was opened on January 10th, 1922, and is staffed by the school. Further information may be obtained from the Laboratory Secretary, School of Tropical Medicine, Pembroke Place, Liverpool, 3.

Psychological Medicine

A knowledge of psychological medicine is an essential part of a doctor's equipment; and in recent years its importance has become increasingly recognized. Its main concern may be said to be with the psychoses—that is, those mental affections which correspond more or less to what is termed insanity—but it embraces also the study of functional nervous disorders in all their varied manifestations, and it includes, in addition, the subject of mental deficiency, which, it must not be forgotten, may form the basis of either a psychosis or a psychoneurosis.

The study of mental illness cannot safely be forgone. All too often a patient meets with some calamity, with all its attendant distasteful publicity, which a knowledge of the practical aspects of mental disease might well have obviated. The treatment of psychotics is the province of the psychiatrist, but their early recognition is of supreme importance; and a working knowledge of such states will afford the practitioner with the means of their detection at a stage when curative measures are most likely to meet with success. Sufferers from one or other of the functional nervous disorders are innumerable, and too many of them pass from doctor to doctor unassuaged. The intervention of the specialist may be necessary in the treatment of the severer forms of hysteria and neurosis; but many practitioners have now acquired a sufficient knowledge of such states to be able to carry out a thorough and effective system of treatment themselves.

Mental deficiency cannot escape detection in its extremer forms, but numerous higher-grade defectives, many of whom are a menace to the community by reason of their criminal propensities, escape recognition; and especially must the student who proposes to take up a career in the school medical service or in the prison service make sure that he is thoroughly grounded in this subject.

It is generally assumed that the mental expert is equally well acquainted with each of these departments of psychological medicine—the psychoses, the psychoneuroses, and mental deficiency. This, however, is seldom the case. In the past there has been too rigid a specialization, largely the outcome of administrative requirements. Recently, owing to the establishment of mental out-patient clinics, and the coming into being of the Mental Treatment Act, which gave sanction to the admission of voluntary patients into public mental hospitals, the psychiatrist's experience has been considerably enlarged; and his province has been still further widened where the authorities have elected to place the selfsame physician in charge of both the psychiatric and the mental deficiency units. It is to be hoped that this process of co-ordination will continue, and that it will eventually embrace the systematic psychological examination of prisoners or, better still, of accused persons awaiting trial.

However that may be, the medical student intending to devote himself to psychiatry will be well advised to neglect no opportunity of furthering his acquaintance with every branch of psychological medicine.

Mental Hospital Appointments

Those who take up psychiatry as a career work as medical officers of public or private mental hospitals or similar institutions. Except in the larger institutions, such as those under the control of the London County Council, where a number of the medical officers are allowed to live out if married, the medical staff are resident officers, having board, lodging, etc., either in the hospital itself or a residence in the grounds. Junior assistant medical officers receive about £350 to £450 per annum, and senior assistant medical officers about £500 to £700, in both cases with board, lodging, laundry, etc., in addition; if married, the board, etc., is commuted for cash. As the mental hospitals are under local control the salaries vary much in different mental hospitals. Medical superintendents, whose pay commonly ranges between £800 and £1,500 per annum, are provided with a house in the grounds of the hospital, and draw various allowances.

Since the passing of the Asylums Officers Superannuation Act of 1909, doctors on the established staff of a public (county or borough) mental hospital, by paying as contributions 3 per cent. of the value of their appointments, may retire at the age of 55 (provided that they have completed twenty years' service), on a pension computed at the rate of one-fiftieth of their salary and emoluments for each completed year of service; but inasmuch as the benefits of this Act are restricted to the public mental hospitals and are forgone on transfer to private or chartered mental hospitals, and the provision for widows is inadequate and uncertain, less inducement is offered than might be to joining the service.

Appointments to the public mental hospitals are made by the visiting committees. Promotion tends to be slow, and uncertain. The higher positions are not always advertised: but in recent years there has been a general improvement in the conditions of service.

Mental hospitals are fast developing an atmosphere approximating more closely to that of the general hospitals. Whilst routine, administrative and clerical, necessarily bulks largely in mental hospital duties, there is ample material, time, and scope for purely medical work and research, and there is no branch of medicine in which research is more needed.

Instruction in Mental Disorder

Though at the present time the instruction given to the student is scarcely adequate to supply the knowledge of mental disorder requisite for the needs of the general practitioner, the facilities for the study of psychological medicine in the general hospitals are now much greater than in former years. Thus many of the teaching hospitals have out-patient departments for the treatment of mental cases, and in some of these hospitals special lectures are given in psychopathology. These facilities need not be utilized by the student, however, and the compulsory part of the curriculum is generally confined to formal lectures and a few attendances at some mental hospital. Here the student is apt to see mainly the advanced states of mental disease, and is likely to gain the impression that mental disorder is necessarily related to segregation and custody. We would therefore impress upon him the importance of attending the out-patient department for mental disorders, where he will be able to observe the mild and early cases such as he will hereafter meet with in general practice.

At the Middlesex Hospital a small number of mental cases are treated in the hospital as in-patients. This is an important move from the teaching point of view, because the student will gain true insight into the relation between mental disorder and medicine as a whole, and he will realize that it is a form of illness to be studied with other diseases and to be treated along similar lines.

In London, post-graduate courses of instruction of a comprehensive kind are given at the Maudsley Hospital and at Bethlem Hospital; and at the National Hospital, Queen Square, courses are arranged to meet the requirements for the diploma in psychological medicine in regard to nervous diseases. Besides its ordinary post-graduate teaching in neurology the West End Hospital for Diseases of the Nervous System holds courses on common disturbances of the nervous system, and provides instruction in neurology for the D.P.M. Courses in mental deficiency are arranged by the University of London. There are also post-graduate courses at the various universities which grant diplomas of psychological medicine or of psychiatry.

There are various facilities for instruction in psychotherapy and for the study of the psychoneuroses. The Institute of Medical Psychology in London has systematic courses of instruction dealing especially with the minor forms of mental disorder which are not usually met with in the mental hospitals. At the London Child Guidance Clinic fellowships are open to medical graduates who hold a diploma in psychological medicine.

Diplomas

Those who are taking up psychiatry as a career will find it essential to obtain a diploma in psychological medicine. Such a diploma is not at present compulsory for a permanent position on the staff of all mental hospitals, but it will probably become so in course of time, just as it is now essential to obtain the D.P.H. if a career in public health is contemplated. Psychiatry is one of the branches of medicine which candidates for the M.D. degree of the Universities of London and Edinburgh can take up, and, in addition, diplomas in psychological medicine (D.P.M.); to which reference has been made, can be obtained from the Universities of London, Edinburgh, Durham, Leeds, Manchester, Dublin, and the National University of Ireland, and from the Conjoint Board in England. The requirements for a diploma differ to some extent in the various universities and colleges.

University of London. (D.P.M.)

The diploma awarded by the University of London certifies that the candidate has passed the examination in psychological medicine with special knowledge of one or other of the two branches, either psychiatry or mental deficiency, special provision being made for this in Part B of the examination. The examination is held twice in each year: Part A in March and October, and Part B in April and November. Part A consists of anatomy, histology, and physiology of the nervous system (one paper and a practical examination), and psychology (one paper and an oral examination). Part B consists of neurology (one paper, and a clinical and an oral examination), and psychological medicine (two papers and a clinical and an oral examination). Paper I tests the candidate's general knowledge of both mental diseases (psychiatry) and mental deficiency, and Paper II is a special one consisting of two separate alternative sections, the first section relating to mental diseases (psychiatry), and the second section to mental deficiency. New Regulations regarding the practice required as a condition for admission to Part B of the Examination will come into force in 1935. A copy of the Regulations and of the Syllabus of Study will be sent on application to John Lea, M.A., University Extension Registrar, University of London, South Kensington, S.W.17.

Conjoint Board in England (D.P.M., R.C.P. and S.Eng.)

Both parts of the examination are held in June and December. The examination comprises the following subjects, with special regard to their relation to psychological and general medicine.—Part I: (a) anatomy (macroscopic and microscopic) and physiology of the nervous system; (b) psychology. Part II: (a) clinical neurology and neuropathology; (b) psychological medicine, including psychoneuroses and mental deficiency, and their legal relationships. The examination will be written and oral in Part I, and written, oral, and clinical in

Part II. No special certificates of study are required for Part I, but before entering for Part II candidates must produce certificates of: (a) having attended clinical instruction for at least two months at a recognized hospital for nervous diseases, or in the department for nervous diseases of a recognized general hospital; (b) having held a resident or whole-time appointment at an institution for mental diseases where clinical instruction is given, recognized for the purpose, for a period of six months, or having attended clinical instruction in psychological medicine at a recognized institution during twelve months. Further particulars may be obtained from the Secretary, Examination Hall, 8-11, Queen Square, London, W.C.1.

University of Edinburgh (Dipl. Psych.)

Candidates for the diploma must have held subsequent to graduation: (a) a resident appointment for one year in a hospital for mental disorders approved by the Faculty; or (b) a six months' appointment as above, and six months' practical study of nervous diseases in a special or general hospital approved by the Faculty. The examination comprises:—Part I: (1) anatomy of the nervous system; (2) physiology of the nervous system; (3) psychology and experimental psychology. Part II: (1) neuropathology; (2) psychiatry and clinical psychiatry; (3) clinical neurology; (4) an additional subject selected by the candidate from a prescribed list. Further particulars may be obtained from the Dean of the Faculty of Medicine, the University of Edinburgh.

University of Leeds (D.P.M.)

The examination is in three parts, and is written, oral, and practical. Subjects of examination:—Part I: (1) the development, anatomy, and histology (human and comparative) of the nervous system; (2) the physiology of the nervous system, and of the organs of special sense; (3) general psychology. Part II: (4) the pathology of the nervous system. Part III: (5) clinical psychiatry; (6) experimental and morbid psychology; (7) (a) clinical neurology; (b) mental hospital administration, (c) medico-legal aspects of insanity. Candidates, in order to pass, must satisfy the examiners in the practical and clinical parts of the examination in Parts II and III respectively. They may present themselves for the three parts of the examination separately, or at the same time, provided that no candidate shall be allowed to pass in Part II unless he has already passed in Part I, or in Part III unless he has already passed in Parts I and II. Evidence must be produced by candidates as to attendance of approved courses of instruction before they submit themselves to Part I of the examination. Particulars may be obtained from the Academic Sub-Dean, School of Medicine, Leeds.

University of Manchester (D.P.M.)

The examination is in two parts. Before presenting themselves for either part of the examination candidates must produce evidence of having attended, subsequent to qualification, certain approved courses of instruction, particulars of which may be found in the prospectus of post-graduate courses. The course of study extends over a period of three university terms, two of which must be taken in the university; the remaining term may be taken at the university, or at some approved institution. The subjects of examination are:—Part I: (1) a written and practical examination on the development, anatomy (human and comparative), and physiology of the nervous system; (2) a written and practical examination in psychology (theoretical and experimental). Part II: (1) a written and practical examination in pathology in relation to the nervous system; (2) a written, clinical, and oral examination in psychological medicine; (3) a clinical and oral examination in clinical neurology. For further information application should be made to the Dean of the Medical School, the University, Manchester.

University of Durham (D.Psy.)

The examination for the Diploma in Psychiatry consists of two parts. Part I: anatomy, physiology, pathology, and bacteriology; Part II: psychology and experimental psychology, neurology and psychiatry (systematic and clinical); and candidates may present themselves for the whole examination or for either part separately. Particulars of the courses of instruction may be had on application to the Dean, College of Medicine, University of Durham, Newcastle-on-Tyne.

University of Dublin Diploma

A post-graduate diploma in psychological medicine is conferred upon registered medical practitioners who have held a resident medical appointment at a recognized institution for the treatment of mental diseases for twelve months, or who have held such an appointment for six months and have attended clinical instruction at an approved institution for six months. Particulars of special courses of instruction may be obtained from the Registrar of the School of Physic, Trinity College, Dublin.

National University of Ireland

The National University of Ireland grants a diploma in psychological medicine. Application should be made to the Registrars of the Constituent Colleges, University College, Dublin; University College Cork; and University College, Galway, for all information as to courses, etc.

Courses of Instruction

Maudsley Hospital, London

A course of instruction for the Diploma in Psychological Medicine is given annually at the Maudsley Hospital, Denmark Hill, from January to May inclusive, the details of the last course being as follows. The course consisted of two parts. In the first part lectures on the anatomy of the nervous system were given by Professor Le Gros Clark, with practical instruction by Mr. C. Geary. A course of lectures on the physiology of the nervous system, with demonstrations in physiological psychology, was given by Dr. F. Golla; a series of lectures on biochemistry in relation to the nervous system by Dr. S. A. Mann; on theoretical and practical psychology by Dr. Henry Devine; on mental mechanisms by Dr. E. Mapother; on contemporary schools of psychology by Professor F. A. P. Aveling; and on the practical application of intelligence tests by Dr. F. C. Shrubbsall. For the second part of the course lectures on the general principles of psychiatry with a series of clinical demonstrations on the same subject were given by Dr. Mapother; on psychopathology and the principles of psychotherapy by Dr. Bernard Hart; on general treatment by Dr. T. Tennent; on laboratory methods by Dr. Mann; and demonstrations on the pathology of the central nervous system by Mr. Geary. Dr. Shrubbsall lectured on mental deficiency, Dr. M. Creak on mental abnormalities of children, and Dr. East on criminal insanity. Dr. Golla and Dr. James Collier gave instruction on clinical neurology, and Mr. Foster Moore on eye changes as applied to psychiatry. Dr. A. J. Lewis gave a series of demonstrations on the psychoneuroses and affective disorders. During the course a series of clinical demonstrations were arranged at the various London county mental hospitals and institutions for mental defectives. The fee for the whole course (Part I and Part II) was 15 guineas, or for either part separately 10 guineas; for one single series of lectures in Part I the fee was 4 guineas, and in Part II 2 guineas. Inquiries as to lectures, etc., should be addressed to the Director of the Central Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E.5, and as to clinical facilities to the Medical Superintendent of the Hospital.

Bethlem Royal Hospital

The Bethlem Hospital is situated at Monks Orchard, Eden Park, Beckenham, Kent, where every facility is available for the clinical study of nervous and mental disorder. The classification of patients is a prominent feature in the administration of the hospital, and treatment in all its modern and specialized aspects can be carried out at the Lord Wakefield of Hythe Treatment and Research Laboratories. When possible two courses of lectures and practical instruction for the Diploma in Psychological Medicine are given each year, in spring and autumn. These are of an intensive character, one commencing in September and completed in early December, and the other commencing in the middle of January and completed in the middle of April. Each course consists of two parts: Part A includes lectures and demonstrations on the anatomy, histology, and physiology of the nervous system, with lectures on psychology and demonstrations in experimental psychology. Part B comprises lectures and clinical demonstrations in psychology, including lectures and demonstrations in the

morbid anatomy of the nervous system; a series of lectures, with clinical demonstrations, on different branches of psychological medicine; and lectures, with clinical demonstrations, on mental deficiency. Entrants for the course who pay a composition fee of 15 guineas may, if due notice is given, attend either Part A or Part B of one course and postpone the other part until the next session. An entrant who wishes to attend one part only pays a fee of 10 guineas. An entrant who takes the complete course can attend the general clinical practice of the hospital on payment of 5 guineas for six months, or 10 guineas for one year, but an entrant who does not take either part of the course and desires to attend the clinical practice of the hospital must pay a fee of 5 guineas for each three months of attendance. To enable post-graduates to obtain special experience in this branch of medicine clinical assistants are appointed from time to time. Further particulars may be obtained from the Physician-Superintendent, Monks Orchard, Eden Park, Beckenham, Kent.

National Hospital, Queen Square

Special courses for the Diploma in Psychological Medicine are not held at the National Hospital, Queen Square, London, W.C.1, but lectures are given which cover all the work necessary for the more organic side of the examination—namely, anatomy, physiology, and pathology of the nervous system and clinical neurology.

The Institute of Medical Psychology

The course of training arranged by the Institute of Medical Psychology, Malet Place, London, W.C.1 (formerly the Tavistock Square Clinic for Functional Nervous Disorders) is not intended to cover the whole field of study for the Diploma in Psychological Medicine. There are post-graduate courses in psychotherapeutic theory and method. The main course, covering one year's work, is arranged for two groups: (a) those who can only manage to devote three hours twice a week; (b) those who, with a view to specialization, are prepared to give as a minimum twelve hours a week (attending on three days). Each group is restricted to a membership of six practitioners. In addition, there is a five weeks' introductory course of lectures. This course forms part of a one-year course in psychotherapeutic theory and method, but may be attended by qualified medical practitioners who wish to take it as an isolated course of lectures. Further particulars may be obtained from the Hon. Lecture Secretary, at the Institute.

The Public Health Medical Services

The Ministry of Health is the central authority to secure the adoption and effective administration of measures conducive to the health of the people, and to promote research work and the proper training of persons for health services.

For the purpose of local public health administration the whole of England and Wales is divided into counties, county boroughs, boroughs, and urban and rural sanitary districts. The administrative County of London, exclusive of the City of London, is divided into twenty-eight metropolitan boroughs.

The public health medical services for Great Britain embrace between three and four thousand medical men and women who give whole-time services, and, in addition, a large number who give part-time services. But little more than one-third of the medical officers of health of England and Wales are whole-time officials; but it is certain that this proportion will be considerably increased in the future, for the Ministry of Health is favourable to whole-time services, and certain provisions of the Local Government Act of 1929 will assist in this connexion. Medical officers for these services are appointed by the Ministry of Health for England; by the corresponding Boards of Health for Scotland and Wales; and by the many local public health authorities.

The Medical Services of the Central Authority

For England, the medical work of the Ministry of Health has been organized under the control of a Chief Medical Officer. It is subdivided into seven sections, with a senior medical officer at the head of each. About a hundred and twenty medical officers are employed, of whom rather more than one-half are regional, and deputy regional medical officers employed for certain duties under the Health Insurance Acts. Briefly, the sections deal with environmental hygiene, epidemiology, and international health; maternity and child welfare; tuberculosis and venereal diseases; the supervision of the food supplies; sanitary administration in relation to infectious diseases; national health insurance; and the school medical service. Vacancies in the staff are advertised from time to time in the medical journals, and appointments are made by the Minister on the recommendations of a Selection Committee. These are Civil Service appointments, subject to the usual conditions as to pension, holidays, etc. Medical officers are also employed for similar services by the Welsh Board of Health (Cardiff) and the Department of Health for Scotland (Edinburgh).

The Medical Services of the Local Authorities

These appointments include: medical officers of health, tuberculosis medical officers, maternity and child welfare medical officers, venereal diseases medical officers, and school medical officers—who work in the health interests of the school child. By the larger local public health authorities assistant medical officers of health are also appointed, and these posts often serve as stepping-stones to the higher offices as vacancies, which are required to be advertised, occur.

Medical Officers of Health

The duties of the medical officer of health are: to inform himself upon all influences affecting, or threatening to affect, injuriously the public health within his district; to advise his sanitary authority upon all matters relating to health; and to perform all the duties imposed upon him by statutes, by-laws, and regulations. He must prepare and submit to his local authority special and annual reports; give immediate information to the Ministry of Health of any serious outbreak of disease; and, subject to the instruction of his sanitary authority, direct or superintend the work of sanitary inspection.

By the Sanitary Officers Order, 1926, no person is qualified to be hereafter appointed or reappointed as a medical officer of health of any district or combination of districts unless, in addition to the qualifications prescribed by any statute, he is also either registered in the *Medical Register* as the holder of a Diploma in Public Health, Sanitary Science, or State Medicine, or has had not less than three years' previous experience of the duties of a medical officer of health.

The Public Health (Officers) Act, 1921, which was promoted by the British Medical Association, provides that a whole-time medical officer of health of a county borough or urban and rural district in England and Wales, a part of whose salary is contributed by the Exchequer, shall not be appointed for a limited period, and shall not be removed from his office except by or with the consent of the Minister of Health. This security of tenure now applies to the large majority of medical officers of health.

Under the Sanitary Officers Order, 1926, a medical officer of health who does not devote his whole time to the duties of his office, but a portion of whose salary is obtained from Exchequer grant, may be appointed without any limit of time; in which case he cannot be removed from office without the consent of the Minister. If he is appointed for a specified term, say one year, he continues to hold office from year to year unless the Minister consents to his removal. Where the electing body pays the whole of the salary of such a medical officer of health he may be dismissed from office without reference to the Minister of Health.

A considerable number of authorities have now adopted the Local Government and Other Officers Superannuation

Act, 1922. Under this Act, if an officer is incapacitated by ill-health after ten years of service, or if he has reached 65 years of age, he is entitled to superannuation. Such superannuation is to be on the following scale: after ten years' service, 10/60 of the average salary which he received during the last five years of employment; after eleven years, 11/60; and so on up to a maximum of 40/60 after forty years or more of service. This Act, however, remains permissive, and it fails to make due allowance, in computing service for purposes of superannuation, for the more advanced age, as compared with other officials, at which the medical officer of health can enter the public service. In these two respects the position reached falls short of that for which the British Medical Association has been working for some years.

In Scotland the position is different in some respects. Under the Public Health (Scotland) Act, 1897, no one can be appointed as medical officer of health for any area unless he possesses the Diploma in Public Health. No medical officer can be removed from office except with the sanction of the Board of Health. A "proper" salary must be paid, and the local authority may not bring about the resignation of the officer by indirect means, such as reducing the salary or attaching new conditions to the appointment. The Act says nothing about superannuation or the age of retirement.

School Medical Officers

School medical officers are appointed by local education authorities. Primarily their duty is to detect among the children attending the public elementary schools any physical or mental defect which may retard education, and to inform the parents of its existence. Most approved schemes of medical inspection include arrangements which facilitate the task of parents in obtaining for their children the necessary treatment, check the results of this treatment, and keep each defective child under skilled observation both at home and at school until it has passed altogether out of the education authorities' hands. Indeed, it is now the practice for the education authorities themselves to provide for certain ameliorative work, notably the prescription of glasses where necessary, dental treatment, the removal of adenoids and tonsils, and treatment in connexion with certain diseases of the skin and some physical and mental defects. The general effect of all schemes alike is to make the inspection imposed by law of benefit, not merely to the individual child, but to the community at large, by preventing the development of conditions which lead to the existence of inefficient citizens among the adult population. The work is so related to that of medical officers of health that, generally, the senior school medical officer fills both appointments, his work, when necessary, being supplemented by that of whole- or part-time assistants. A diploma in public health is almost always required of those entering the school medical service.

In Scotland, while the statutory authority for the work of the school medical service is different, the scheme of work is broadly the same.

Tuberculosis Medical Officers

A tuberculosis medical officer is an officer with special training and experience in tuberculosis work, and of a suitable age and attainments to command general confidence. In England such officers are appointed by county councils and county borough councils, and their duties are to carry out the work of diagnosis of tuberculosis, to advise as to treatment, and to take charge of the work of tuberculosis dispensaries and sanatoriums where these are in operation. The work under tuberculosis schemes is co-ordinated with the general public health work of local authorities, and so the medical officer of health is often appointed as the chief tuberculosis officer when a special tuberculosis officer is on the staff of the local authority. The arrangements in Scotland are very similar. In Wales tuberculosis work is carried out under the aegis of the Welsh National Memorial Association, upon which the constituent local authorities are represented, and the powers of appointment of tuberculosis officers are vested in the Association.

Maternity and Child Welfare Medical Officers

Any local public health authority, however small, may make arrangements for maternity and child welfare work within its area, although very generally the smaller local authorities are provided for in county council schemes; but the Minister of Health may transfer the administration of the maternity and child welfare work of an area to the local education authority where this would conduce to more efficiency. For the schemes of the smaller local authorities the services of a part-time medical officer are obtained when the medical officer of health does not himself undertake the duties; but for the larger schemes special whole-time appointments are made. The maternity and child welfare medical officer is responsible for the work at the centres provided and for directing the home visitations; and these activities are closely co-ordinated with the other branches of public health work directed by the medical officer of health.

Much of this work was commenced in different parts of the country by voluntary organizations; some of it still remains in their hands, but is now fairly closely linked up with the public health local authority; and the tendency is for the whole of it to be undertaken by the local authorities. A large number of women medical officers have been appointed to these posts.

Veneral Diseases Officers

Schemes for the diagnosis and treatment of venereal diseases are provided and administered by county councils and county borough councils. In some cases the officer is on the whole-time public health staff, and in others he is a part-time official. Special knowledge and practical experience in the treatment of venereal diseases are essential. The officer appointed for either whole-time or part-time service works at one or more clinics, and also gives instruction and assistance in the treatment of venereal diseases to general practitioners, who, if they desire to obtain experience, are allowed to attend the clinics.

Remuneration in the Public Health Service

In order to ensure that public health authorities may obtain skilled and highly trained medical officers it is essential that such officers should receive salaries commensurate with their attainments, bearing a reasonable relationship to the time and money expended in fitting them for their important and responsible duties, and comparing well with the income which might be secured in other lines of medical work. With this end in view the British Medical Association and the Society of Medical Officers of Health prepared a scale of minimum commencing salaries for whole-time public health medical officers.

The scale, which was put into operation in 1925, was attended with a large measure of success. There were, however, certain aspects of it which were not entirely satisfactory. For instance, it was not retrospective, and did not, therefore, apply to medical officers who had been appointed prior to the date on which it came into force, and it contained no provision for specified increments in salary.

As the result of a series of conferences between representatives of the various Associations of Local Authorities and the British Medical Association and Society of Medical Officers of Health, under the chairmanship of Lord Asquith, a "Memorandum of Recommendations" in regard to salaries of public health medical officers was drawn up and came into force in June, 1930. This Memorandum was published in the *Supplement to the British Medical Journal* of July 27th, 1929 (p. 71). Copies of the Memorandum may be obtained from the Medical Secretary of the Association. It has been adopted by the Representative Body, and has been accepted by the representatives of the following bodies representing local authorities:

- The Association of Municipal Corporations.
- The Urban District Councils Association.
- The Rural District Councils Association.
- The London County Council.
- The Association of Education Committees.
- The Mental Hospitals Association.
- The Metropolitan Boroughs Standing Joint Committee.

It has not been accepted by the county councils as a whole, but a majority of these authorities have adopted, and are applying, the Memorandum. The advertisements of local authorities which are not prepared to put into effect the whole of the Recommendations, will not be published by the *British Medical Journal*, which in this matter has the co-operation of the *Lancet* and the *Medical Officer*.

The great advantage of the Memorandum is that it embodies a general agreement as to salaries and conditions of service, and is not merely a scale of salaries. It is retrospective, and will therefore benefit officers appointed before it came into force. It provides stated increments for practically all medical officials except whole-time chief, deputy, and chief assistant medical officers of health, who, as chief medical officials, may, it is presumed, depend that the commencing salaries mentioned in the agreement will be increased for meritorious work and years of service, and it contains a very valuable provision by which questions of difficulty can be referred to an advisory committee.

The British Medical Association represents the profession on the advisory committee, putting the point of view of the public health officers in the discussion of the cases of those who are receiving remuneration less than that laid down in the scale.

For the right class of practitioner with leanings in the direction of public health work the service offers an attractive career, but it must always be remembered that there are comparatively few posts which carry high salaries.

The Curriculum for the Diploma in Public Health

New Regulations and Rules of the General Medical Council for Diplomas or Degrees in Public Health came into force on October 1st, 1931.

The curriculum must extend over a period of not less than twelve calendar months (or an academic year of whole-time study covering a period of not less than nine calendar months) subsequent to the attainment of a registrable qualification.

Every candidate for Part I of the examination for the D.P.H. must produce evidence of having attended, during not less than 280 hours, at an institution approved by the licensing body granting the diploma, practical instruction in:

(a) Bacteriology and parasitology (including immunology, serology, medical entomology, etc.), especially in their relation to diseases of man, and to those diseases of the lower animals which are transmissible to man;

(b) Chemistry, physics, radiology, and electrology in relation to public health;

(c) Physiology and biochemistry in their application to nutrition and hygiene;

(d) Meteorology and climatology in relation to public health.

Every candidate for Part II must produce evidence of having received, during not less than 120 hours, at an approved institution, instruction in the following subjects:

(a) The principles of public health and sanitation;

(b) Epidemiology and vital statistics;

(c) Sanitary law and administration (including public medical services);

(d) Sanitary construction and planning.

Every such candidate must also have attended for three months on the clinical practice of a recognized hospital for infectious diseases, and have received therein instruction in the methods of administration. At least twenty-four daily attendances of not less than two hours each are required.

Every candidate for Part II must also produce evidence that he has, during a period of not less than six months, been engaged in acquiring a practical knowledge of the duties of public health administration under the supervision of a medical officer of health, who must certify that the candidate has received, during not less than three hours on each of sixty working days, practical instruction in these duties, and also those relating to:

(a) Maternity and child welfare service;

(b) Health service for children of school age;

(c) Venereal diseases service;

(d) Tuberculosis service;

(e) Industrial hygiene;

(f) Inspection and control of food, including meat and milk.

(Instruction in (a) to (f) must include attendance at the centres, clinics, institutions, and premises concerned.)

Certificates of having received this prescribed instruction in public health administration must be given by a medical officer of health who devotes his whole time to public health work; or by the medical officer of health of a sanitary area having a population of not less than 50,000; or in Ireland by the medical superintendent officer of health of a county or county borough having a population of not less than 50,000.

'Regulations for the Diploma in Public Health

The Examination

The examination for the D.P.H. is divided into two parts, and no candidate is allowed to sit for the final part until after an interval of two years from the date of his obtaining a registrable medical qualification, which must be registered in the *Medical Register* before admission to Part II of the examination. The object of this two years' interval is "to provide opportunity for candidates, while passing from the state of pupilage to that of responsible practice, to give mature consideration to the obligations and duties involved in the work of the Public Health Service, and to acquire direct experience of medical work in a responsible capacity, in general medical practice, in hospital or laboratory appointments, or in any special branch of clinical work or study related to State Medicine."

The examination for Part I embraces practical, written, and oral tests in the subjects set out in the Regulations of the curriculum relating to that part; and the same is true of the examination for Part II.

A candidate must pass in all the subjects of Part I before being admitted to the examination for Part II.

Any candidate who possesses a qualification entitling him to registration on the British, Dominion, or Foreign List of the *Medical Register* can be admitted to examination, provided he has complied with the regulations of a licensing body in the United Kingdom based on the rules of the General Medical Council, and that before being admitted to Part II of the examination his qualification has been registered in the United Kingdom. Only diplomas in public health granted by approved bodies in the United Kingdom are registrable in the *Medical Register*.

Training and Examining Centres for Public Health Qualifications

Degrees in Sanitary Science are conferred, in England, by the Universities of London, Durham, Liverpool, and Birmingham; in Scotland, by the Universities of Glasgow and Edinburgh; and in the Irish Free State, by the National University of Ireland. In most cases these degrees are conferred only upon medical graduates of the universities granting them.

Whereas the requirements of the General Medical Council for the Diploma of Public Health are strictly conformed to, these requirements are extended, as a rule, as to both the period and the scope of special studies demanded, before Degrees in Sanitary Science are granted.

Most universities in Great Britain and Ireland grant a D.P.H. and provide for the necessary training.

The English and Scottish Conjoint Boards and the Irish Colleges also grant these diplomas. The School of Physics of Trinity College, Dublin, was the first body in the British Isles to arrange for courses of instruction and for a Diploma in Public Health.

At Cambridge the teaching and training courses for the D.P.H. were terminated at the end of 1931.

The post-graduate teaching and training in public health, in London, is provided mainly at one centre—the London School of Hygiene and Tropical Medicine.

(University of London); the only other training centre which offers such facilities is the Royal Institute of Public Health, Queen Square, Bloomsbury, W.C.1.

The course of study for the D.P.H., as provided by the London School of Hygiene and Tropical Medicine (Keppel Street, Gower Street, London, W.C.1), which is a School of the University of London, covers a period of nine calendar months in the case of whole-time students, and is so designed that students wishing to do so can proceed to the academic diploma instituted by the University of London. The School undertakes research work in preventive medicine, and members of the public health services have a common room placed at their disposal, and are privileged to attend staff and special lectures.

The University of Manchester has a well-equipped department of bacteriology and preventive medicine, where candidates preparing for the examinations of the various university and examining boards for the Diploma in Public Health can obtain instruction. It also prepares candidates for the Diploma in Bacteriology and in Veterinary State Medicine, granted by the university. Full particulars can be obtained from the Dean of the Medical School, the University, Manchester.

The University of Edinburgh grants a Diploma in Public Health. The course, which extends over an academical year of nine months' full-time study, can be commenced in October only, and provision is made by the university for instruction in all the subjects. Candidates for the diploma must be graduates in medicine and surgery of the University of Edinburgh, or must hold corresponding degrees or registrable medical qualifications, which must be registered before a candidate is admitted to examination. The course for the diploma is divided into two parts, for each of which examinations are held twice annually. In each part the candidate must pass in all the specified subjects at one examination. Admission to the examinations is contingent upon the candidate having complied with the following conditions:

PART I.—(a) Completion, subsequent to obtaining a registrable medical qualification, of the course of instruction prescribed for Part I.

PART II.—(b) Completion, subsequent to obtaining a registrable medical qualification, of the course of instruction prescribed for Part II. (c) A lapse of two years after obtaining a registrable medical qualification. (d) Previous passage of examination in all subjects of Part I.

Further particulars can be obtained from the Dean of the Faculty of Medicine, Edinburgh.

The University of Glasgow confers the B.Sc.(P.H.) and the D.P.H., and conducts complete qualifying courses for both at its Institute of Hygiene and, for administrative work, in the Public Health Department of the city. The course for the diploma is divided into two parts, and admission to the examination is contingent upon the candidate having complied with the following conditions:

PART I.—(a) Completion, subsequent to obtaining a registrable medical qualification, of the course of instruction prescribed for Part I.

PART II.—(b) Completion, subsequent to obtaining a registrable qualification, of the course of instruction prescribed for Part II; (c) a lapse of two years after obtaining a registrable qualification; (d) previous passing of examination in all subjects of Part I.

The Royal Naval Medical College and the Royal Army Medical College provide courses of training to the medical officers of these two services.

Degrees and Diplomas in Public Health are registrable qualifications, but not so those in Tropical Medicine and Hygiene.

Qualifications in Tropical Medicine and Hygiene

The University of London grants a degree (M.D. in Tropical Medicine) to its medical graduates. A course of training is normally required, extending over at least one academic year.

Diplomas in Tropical Medicine and Hygiene are granted, in England, by the University of Liverpool and by the English Conjoint Board; and, in Scotland, by the Uni-

versity of Edinburgh. Among the institutions which provide qualifying courses are the London School of Hygiene and Tropical Medicine, the Liverpool School of Tropical Medicine, and the Royal Army Medical College. In the last-mentioned institution the training provided is restricted to Army medical officers. The training period for these diplomas is about six months. Graduates of medicine and surgery of recognized universities whose degrees are not registrable in this country may enter for the examination of the English Conjoint Board, and the conditions of study may be modified on the grounds of previous work in the Tropics or of original investigations undertaken.

The Colonial Office has decreed recently that the holder of a D.F.M. and H., or of a D.T.H., is eligible for appointment as a medical officer of health in places and districts other than those with large populations. In the latter cases a D.P.H. is required.

Those wishing for the details of syllabus of study, fees, date of commencement of the training courses, and the dates of examinations, etc., should apply to any of the training schools mentioned.

The Services

ROYAL NAVAL MEDICAL SERVICE

The revised regulations and conditions of service arising out of the Warren Fisher Committee Report have recently been published by the Admiralty, and it is considered that the Naval Medical Service now offers to well-qualified medical men a satisfactory career, with good opportunities for the practice of their profession and for specialization in many subjects, good pay, and the prospect of promotion to the higher ranks with an adequate pension on retirement.

Summary of New Conditions

The following information embodies the principal changes in conditions.

Entries will be on a short-service basis, and will be for an initial period of three years, to be extended to five years at the discretion of the Admiralty.

Officers leaving the Service at the end of three years will be eligible for a gratuity of £400, whilst those who leave at the end of five years will receive £1,000.

Officers may be transferred to the Permanent List at the discretion of the Admiralty on completion of five years' short service. A gratuity of £1,000 will be paid, but the officer will be required to render a minimum of twenty-five years' service in order to qualify for full pension, including seniority granted, if any, in respect of civil hospital time. With regard to the latter, ante-date of seniority of not more than one year may be allowed in respect of resident appointments in civil hospitals held prior to entry to the Royal Naval Medical Service. The ante-date will count for seniority and eligibility for increase of pay, and if the officer is transferred to the Permanent List it will count also as service for the purposes of promotion and retired pay, or gratuity on retirement.

Opportunities will be afforded for officers to specialize during the course of their career, and the number of specialist posts carrying additional emoluments has been increased from sixty to eighty-three.

The age of retirement has been increased in the case of surgeon commanders from 50 to 55, and in the case of surgeon captains from 55 to 57, thus affording officers the prospect of a longer career on full pay.

Candidates should preferably be between the ages of 24 and 28.

Medals and Prizes

Gilbert Blane Medal.—This medal is awarded annually to the surgeon lieutenant commander who obtains the highest aggregate marks at the examination for promotion to the rank of surgeon commander. The award is subject to the approval of the Presidents of the Royal Colleges of Physicians and Surgeons respectively and the Medical Director-General of the Navy.

Other awards and prizes open to naval medical officers are the Chadwick Naval Prize, the North Persian Forces Memorial Medal, and the Parkes Memorial Prize.

MEDICAL BRANCH OF THE ROYAL AIR FORCE

SEPT. 1, 1934]

Retired pay consists of two parts: (a) a service element based on the officer's total service; (b) a rank element for the substantive rank from which the officer retires. An officer with less than twenty complete years' service will not be eligible for retired pay on voluntary retirement. The following are the maximum current rates of retired pay:

Rank	Yearly Rate of Retired Pay	Compulsory Retiring Age
Major	£ 435	55
Lieutenant-Colonel	540	55
Colonel	720	57
Major-General	900	60
Lieutenant-General	1,030	60 (or on completion of tenure)

Gratuities

A short-service officer not appointed to a permanent commission may retire with a gratuity of £1,000 after five years' service as a medical officer. Such an officer is liable, during the twelve years following retirement, to be recalled to service at a time of national emergency.

Officers, holding permanent commissions, with less than twenty years' service as medical officers may be permitted to retire with gratuities in accordance with the following scale:

With less than 10 years' service as a medical officer	£1,000
After 10 years' service as a medical officer	£1,500
After 15 years' service as a medical officer	£2,500
After 18 years' service as a medical officer	£3,500

Further Information

Entry takes place twice yearly, at the beginning of May and November. The regulations for admission, giving full details, can be obtained from the Under Secretary of State (A.M.D.1), War Office, Whitehall, London, S.W.1, and should be carefully studied. A personal interview with a representative of the Director-General, Army Medical Services, is readily obtainable.

The Army Dental Corps

The corps is administered by the Director-General, Army Medical Services. The regulations for admission to the Army Dental Corps should be obtained from the Under Secretary of State, War Office, and carefully studied.

MEDICAL BRANCH OF THE ROYAL AIR FORCE

The establishment of the Royal Air Force Medical Branch consists partly of permanent and partly of short-service officers, and candidates are appointed after interview by the Selection Board, without competitive examination. Candidates must be under 28 years of age, be British subjects, the sons of British subjects, and of pure European descent. Before acceptance they will be required to pass a medical examination.

An officer will on first entry be granted a short-service commission for a period of three years on the active list (which may be extended to five years), followed by four years' service in the reserve, and those under 28 years of age at the time of entry will be eligible for subsequent selection for permanent commissions should they be desirous of remaining in the Service. The prospect of obtaining a permanent commission is approximately an even one so far as can reasonably be estimated at present. Hospital appointments held since qualifying will, under certain conditions, qualify candidates for appointment to a permanent commission being, if necessary, extended by a period equal to the "antedate."

Pay and Allowances

The following table shows the current rates of pay per annum for the various ranks. In addition to pay, officers receive quarters (with fuel and light), rations and attendance, or, if these are not available in kind, they are given cash allowances in lieu as shown in the table. The rates and general scheme of allowances are subject to review as circumstances may require. Married officers who have attained the age of 30 years receive either married quarters or allowances at the married rates.

Rank	Pay (per annum)	Allowances (per annum) (Present Home Rates)	
		Married	Single
Flying Officer	£ 395	£ —	£ 113
Flight Lieutenant	428	228	119
Ditto, after 2 years as such	459	228	119
Ditto, after 4 years as such	493	228	119
Squadron Leader	642	231	157
Ditto, after 2 years as such	705	231	157
Ditto, after 4 years as such	739	231	157
Ditto, after 6 years as such	806	234	166
Wing Commander	905	234	166
Ditto, after 2 years as such	977	234	166
Ditto, after 4 years as such	1,034	266	216
Group Captain	1,150	362	307
Air Commodore	1,314	423	358
Air Vice-Marshal	1,642		

Special allowances are applicable at stations abroad. The rates of pay of the Royal Air Force Medical Branch are fixed on an inclusive basis, and the fact that specialist pay and charge pay are not payable as separate emoluments was taken into account when the rates were fixed.

At about five years' service all permanent officers who are judged suitable will be given the opportunity to take a course of specialist study. The period allowed will vary with the subject of study, but normally about nine months will be available to each officer, during which full pay and allowances will be issued. Their subsequent career will normally be as follows. Approximately three-quarters of the employment of squadron leaders and senior flight lieutenants is in specialized posts, though these are not generally of a full-time specialist character. On reaching the rank of wing commander the policy is to allow a proportion of officers to become permanent specialists and to be employed continuously throughout their service in the ranks of wing commander and group captain. In addition, there are a number of hygiene posts in the former rank open to specialists in that subject, bringing the proportion of specialist posts in the rank of group captain to a half of the total posts. In the rank of flight lieutenant a half of the posts already mentioned are available for the permanent specialist. This statement indicates the position between posts in charge of a large hospital and headquarters administrative posts. As regards specialist employment as at present foreseen. No guarantee can be given, of course, that the career of an individual will necessarily conform to the forecast. New entrants into the Medical Branch of the R.A.F. will be commissioned as flying officers (Medical), and will be selected for permanent commissions after ten years' total service to the rank of squadron leader after ten years' total service. Accelerated promotion may be granted to officers qualified to hold specialist appointments after the completion of eight years' service. Promotion within establishment to the ranks of wing commander and above will be by selection. The number of permanent commissions granted yearly is regulated with a view to all suitable permanent officers being promoted to wing commander and of a substantial majority of wing commanders being promoted to group captain. While the aim is to give entrants a career as above, no guarantee of promotion can be given to the individual officer of course, since the number of vacancies for promotion must depend on the requirements of the Service from time to time.

Outfit Allowance

An officer who has not previously held a commission in H.M. Forces will receive an outfit allowance of £50 on joining. Short-service officers who complete their full period of service on the active list will normally be granted gratuity as follows on transfer to the reserve:

After 3 completed years	£100
After 5 completed years	£120

Further particulars may be obtained from the Under Secretary of State for India, Military Department, India Office, London, S.W.1.

SEPT. 1, 1934]

LOCAL GOVERNMENT HOSPITAL SERVICES

LOCAL GOVERNMENT HOSPITAL SERVICES

As a result of the Local Government Act, 1929, many of the former Poor Law hospitals, which were available only for the destitute poor, have become municipal hospitals, available for the benefit of the public generally. The number of hospitals provided by Sir George Newman to be 858, with 143,494 beds. Of this number 326, with 57,129 beds, are administered under the aegis of public health, and 532, with 86,365 beds, under that of public assistance. The total compares with 988 voluntary hospitals, having 71,956 beds.

The Growth of the Municipal Hospital

The appropriation to general and special hospital use of so much institutional provision, inherited from the now defunct boards of guardians, means not only the separation from the Poor Law of the services performed in such institutions, but the better co-ordination of the public health services of the local authorities in general. It is not too much to say that the Local Government Act of five years ago has created the beginnings of a national hospital system with which it is important that the voluntary hospital system, without losing its character and tradition, should be integrated. With these large municipal developments there has come about a vast expansion of opportunities for medical service under the local authorities. The institutions which, so long as they remained Poor Law infirmaries, were disliked it not dreaded by the poor, and largely disregarded by the medical profession, have now, as municipal hospitals, come to fill a very large and important place in the hospital picture.

The London County Council Services

The London County Council is the largest of the local authorities in respect of the hospital accommodation it controls and the medical staff which it employs. It has set an example by the advantage which it has taken of the Local Government Act. Under that Act it took over a total of seventy-six hospitals and institutions. These included twenty-eight general hospitals, the largest of which is Lambeth, with accommodation for 1,480 patients; a total of seventy-six general hospitals, the largest of which is Lambeth, with accommodation for 1,480 patients; seven of the others have accommodation for over 700. The total cost of maintenance of the various hospital services is some four and a half millions a year, of which nearly three millions is spent on the general hospitals. The total bed accommodation in the hospitals and allocated institutions on transfer was 41,164, but this included nearly ten thousand beds in institutions and allocated which could not be regarded as suitable for the proper treatment of sick persons. A great deal of structural work and readaptation was put in hand, with the result that a net increase of more than 1,400 beds has been provided.

There are admitted to these hospitals a large number of acute cases, both medical and surgical, but there is, of course, this difference between them and the voluntary hospitals, that the latter can select their patients and reject whom they please, whereas the rate-supported institutions must be prepared to admit any sick person who applies, provided that, in the opinion of the medical superintendent, such a patient is suitable for admission. Some 25,000 operations were performed in these hospitals during the last year for which full records were available, and the number of out-patient attendances was a quarter of a million. The chronic sick poor are gradually being concentrated in twelve other institutions which, unlike the rest, are for the present, for administrative reasons, not under the Public Health Act. So far as maternity and child welfare services are concerned, the City Corporation and the Metropolitan Borough Councils are the responsible authorities, but the London County Council has maternity beds in its general hospitals, and in several hospitals, a fully equipped maternity and gynaecological block. To the maternity wards of the Council's hospitals last year over 10,000 cases were

admitted. The accessory medical services under the Council are also important; these include pathological laboratories, x-ray units, and a large ambulance organization. In addition to smaller units, the Council has five pathological laboratories, each of which serves a group of institutions attached to the municipal service. These five are at Lambeth, Highgate, Lewisham, Mile End, and Kensington. Recently arrangements have been made whereby post-graduate students of the London School of Hygiene and Tropical Medicine may obtain experience of the technical and administrative methods adopted in these laboratories—experience of a kind very difficult to obtain in the ordinary way.

English and Scottish Cities

The same general provisions hold good, in smaller degree, of other progressive cities. *The Hospitals Year Book, 1934*, gives particulars of twenty-two large general hospitals in provincial cities, administered by local authorities under the Public Health Acts or the Local Government Acts. The average bed accommodation in these twenty-two hospitals is close upon 500, and the whole-time medical staff numbers 100, and the part-time staff 129. Two hospitals in Birmingham—Dudley Road, and Selly Oak—have between them bed accommodation for 1,446, and a staff, whole- and part-time, of thirty-seven. Newcastle-upon-Tyne, in its municipal hospital with 680 beds, has a staff of eighteen. Southampton, with 450 beds, and of eleven. Particulars are also given of twenty-four provincial hospitals which remain under the Poor Law. The whole-time staff attached to these hospitals numbers 105, and the part-time staff 127. In Scotland figures are given for three hospitals in Edinburgh, administered under the Public Health Acts, having accommodation for 940 patients, a whole-time medical staff of eight, and a part-time staff of twenty-three; and in Glasgow of five Poor Law hospitals, accommodating 3,300 (with over 3,000 of the beds, on the average, occupied daily), and with a staff of four medical superintendents, thirty-three whole-time assistant medical officers, two part-time specialists, officers, and twenty-two part-time specialists. In addition to the large general hospitals maternity and children's hospitals are provided by the larger authorities. In Birmingham, for instance, there are twenty-eight maternity and child welfare centres under the control of the Public Health Committee, as well as four sanatoria, two infectious diseases hospitals, two maternity homes, two infants' hospitals, and four convalescent homes.

Facilities for Instruction

A great amount and variety of clinical material is contained in these hospitals, and many of them are used for undergraduate and post-graduate teaching. In London some useful discussion has taken place between the voluntary County Council and the representatives of the hospitals under the County Council and the general hospitals under the old board of guardians arrangements for instruction since the hospitals came under Council control. Facilities for clinical demonstrations are now available at a number of the Council's hospitals, and for this purpose each teaching hospital in London is associated with one or more municipal institutions. Teaching in obstetrics is afforded in two at least of the Council's pathological laboratories to post-graduate students in order that they may obtain experience in technical and administrative methods. As an example of the amount of material which may be afforded by a Council hospital, St. James's, Wandsworth, may be cited, where there is a clinic of fifty beds always occupied, and where there is a clinic of fifty beds always occupied, and where there is a clinic of fifty beds always occupied, and where there is a clinic of fifty beds always occupied. The post-graduate school at Hammer-smith Hospital, the result of a partnership between the Government, the University of London, and the London County Council, will be opened during this autumn. So much has been written about this development that it is hardly necessary to recapitulate here all that it intends. The

new institution has been "recognized" as a school of London University. There will be four professorships, three in the main clinical subjects—medicine, surgery, and midwifery and gynaecology—and the fourth in pathology. The school buildings will consist mainly of laboratories, lecture theatres, and other accommodation (non-residential), while the associated developments and adaptations of the Hammersmith Hospital adjoining will include two new blocks of buildings for the casualty, receiving, and out-patient departments, a new ward, a massage and light treatment section, and other facilities. One recent decision of the County Council is to provide at Hammersmith a radiological department which shall be a consultative centre for the whole of the hospital service, where cases can be sent from other hospitals for expert opinion on diagnosis and treatment.

It may be added that the clinical material in municipal hospitals is not only vast in amount, but includes a great deal with which it is very important that the young practitioner should be familiar, and which is not much represented in the teaching hospitals. In a recent report to the L.C.C. it is mentioned that the type of case treated in the general hospitals is altering, and there is a continually increasing amount of acute and operative work to be carried out.

Medical Staffing

The policy pursued by the London County Council and other authorities is to provide a whole-time medical service and to have a permanent staff at each general hospital. The grades of officers are: medical superintendents, deputy medical superintendents, senior assistant medical officers, assistant medical officers, and house-physicians and surgeons (resident), and part-time clinical assistants (non-resident). The medical superintendent is required to be a man of high qualifications in at least one branch of medicine, as well as a good administrator and first-class technician. In addition to the medical superintendent, one or more whole-time medical officers, with special qualifications in medicine, surgery, or obstetrics, are appointed. Preference is given to officers holding the higher medical qualifications, M.R.C.P. or M.D. in the case of physicians, F.R.C.S. or M.S. in the case of surgeons. These are graded as senior assistants, and at the larger hospitals one of them ranks as deputy medical superintendent. Deputy medical superintendents are employed as a rule only at hospitals with over 600 beds, of which there are sixteen among the London County Council general hospitals. These officers at institutions with over 750 beds are described as of Grade I, while those at hospitals of from 600 to 750 beds are of Grade II. Senior assistant medical officers are also graded according to the size of the hospital they serve. The appointment to these posts is made to qualified medical practitioners of at least one year's standing in their profession who have held a residential post for at least six months in a general hospital. Those who seek assistant medical officerships at the special hospitals will find general hospital experience desirable, although the lack of it does not debar otherwise suitable candidates. The engagements of assistant medical officers of Grade I are limited to four years, terminable at any time by a month's notice on either side, and the first year of service is on probation. Should the officer's name be on the promotion list at the end of his four years' term, he may remain beyond the period of the original engagement, and at an increased salary. Assistant medical officers of Grade II are on a yearly engagement, but this has been found unsatisfactory to the Council, because of the need for frequent appointments, and because officers leave at a time when, having learnt the ways of the hospitals, they are most useful. It is proposed to renew such appointments for a second year. The junior appointments are those of resident house-physicians and surgeons and part-time clinical assistants. These officers consist of recently qualified men and women who are appointed for limited periods, generally six months, and need not have had previous hospital experience. The six months' period may be extended for further similar periods up to a maximum of two years, provided that not more than twelve months is spent in one hospital.

Scale of Salaries

Medical superintendents in London receive as a maximum between £900 and £1,650 per annum, including an unfurnished house or quarters, valued at £100 a year for superannuation purposes, and the rates on which are paid by the Council. The salary scales are:

General Hospitals	£900 to £1,550
Convalescent Hospitals	£900 to £1,100
Fever Hospitals	£900 to £1,450
Tuberculosis Institutions	£900 to £1,200
Children's Hospitals	£950 to £1,650

Of the general hospitals only two of the smallest in the London County Council area have a commencing salary of £900; at the other end of the scale two have commencing salaries of £1,300. One condition made is that the appointment is to the Council's hospital service, not to an individual hospital, and appointment to the service includes liability, if called upon, to take part in consultations or perform operations at another hospital, although if this happens frequently, on account of the special skill or experience of the officer concerned, a claim for extra remuneration may be considered. Further, in addition to their ordinary remuneration as medical superintendents, the chief medical officers of the infectious hospitals service and of the children's institutions and surgical tuberculosis service receive an allowance at the rate of £200 a year, and the chief medical officer of the medical tuberculosis service, who is also a medical superintendent at a hospital, an additional allowance at the rate of £125.

The scale of salaries for other officers, subject to certain modifications in the different hospitals, is as follows:

Medical Appointments	Remuneration*		
	Minimum	Increase	Maximum
Deputy medical superintendent (Grade I) ...	£ 650	£ 50	£ 800
" " " (Grade II) ...	600	30	750
Senior assistant medical officers (Grade I) ...	550	25	650
" " " (Grade II) ...	500	25	600
Assistant medical officers ...	350	25	425
" " " (yearly engagement)	250	—	—
House-physicians and house-surgeons ...	£120 (resident)		
Clinical assistants (non-resident) ...	£150 (non-resident) and no emoluments, but meals when on duty		

* Exclusive of the emoluments of board, lodging, and washing, valued at £150 per annum in each case.

In the country generally medical superintendents of Poor Law infirmaries are paid from £600 a year upwards to £1,600, with emoluments; deputy medical superintendents, from £450 to £750, with similar emoluments, and resident assistant medical officers, from £200 to £450, with full board.

Residence, Leave, and Pensions

Generally speaking, all assistant medical officers in London are required to be resident. If in any case the question of an assistant medical officer being non-resident should arise, the primary consideration is the interests of the service. The emoluments of board, lodging, and washing are valued at £150 a year. Non-resident medical officers who are receiving the allowances in lieu of residential emoluments pay for any meals taken at the hospital. Permission to live out is granted only if the accommodation is required or can be utilized for some other purpose.

Liberal annual leave, with pay, and sick leave, with pay, for a reasonable period are allowed by the L.C.C. Leave is also granted for study purposes, not only to officers who are following a university course, but to those who are undertaking other courses of study or research work. The house-physicians and surgeons are not regarded as employed in a whole-time capacity, and reasonable off-duty periods for study are allowed. Clinical assistants attend six sessions of four hours' duration each week. Assistant medical officers also are allowed to improve their qualifications, and leave of absence not exceeding six weeks in any one year may be granted, with rates of pay varying in accordance with the service of the officer. Occasional daily leave for attending a course of instruction for a medical degree or diploma is granted with full pay. These concessions, however, are subject to the condition that

SEPT. 1, 1934]

PRISON MEDICAL SERVICE

the officer shall continue for a certain period in the service of the Council.

Whole-time permanent appointments are pensionable under the Council's superannuation and lump sum payment after the necessary qualifying period of service. Pensions are also payable to officers on the fund who break down in health after not less than ten years' service. Officers resigning have their contributions returned to them, and death benefit is also paid in respect of officers of five years' service or more. A point to bear in mind is that under the London County Council regulations—and the same very widely applies to other authorities—the marriage of a woman officer puts an end to her contract of service with the Council. With certain exceptions, married women are ineligible for employment or re-employment.

Consultant and Specialist Services

Under the new scheme, which came into operation in 1933, the general hospitals have been divided into seven groups on a geographical basis, and the special hospitals and public assistance institutions in the area linked up with them, so that consultants and specialists, who were previously engaged chiefly for individual hospitals, are now appointed to the service and utilized as required for the groups of hospitals. The salaries for the part-time consultants and specialists are generally £125 a year for one session a week, £200 for two sessions, £275 for three sessions, £350 for four sessions, £425 for five sessions, and £500 for six sessions. Full-time consulting physicians and surgeons receive £1,250 a year, rising by increments of £50 to £1,500 a year, with no emoluments. The full-time radiologists receive £900 a year, rising by increments of £50 to £1,100. The appointment of part-time consultants and specialists is subject to annual review.

Method of Entrance to the Service

Many provincial areas have now highly developed schemes providing for the employment of many medical men and women of high qualifications at salaries of from £450 to £800 per annum, and, in addition, large numbers of junior officers at salaries of from £200 upwards are employed. These posts offer to all grades remarkable facilities, which should appeal to those who desire to gain experience and at the same time wish to adopt for a period the institutional life. It is a service in which the original appointment and any subsequent promotion depend upon merit, and in which vacancies in the higher grades are filled as far as possible from the existing staff, with no barrier preventing transference from one grade to a higher. Vacancies are usually advertised in the medical journals.

The opportunities of the local government hospital service to those whose career will be spent in general or consultant practice, as well as to those who expect to spend their lives in the public health service, scarcely need to be stressed. One point which the final-year student or the newly qualified practitioner will do well to bear in mind is that some authorities in offering appointments insist upon candidates possessing previous resident hospital experience. Such a requirement may not arise for some years, but the medical man or assistant who has gone direct to serve as locum tenens or assistant may find himself or herself cut off from certain avenues of work through having neglected to take resident experience immediately after qualification. We are informed that it almost the rule for the young medical man to take a residential post, but the certainly deplorable often forgoes this experience. It is certainly ignorance on that a competent man should, through ignorance of qualification, deprive himself of the opportunity following his bent in later years.

It has to be borne in mind, however, that the attractiveness and opportunity of a post under the new public assistance authorities, notwithstanding the effect of the Act of 1929, in assimilating the Poor Law to other public health services, are affected not a little by the policy adopted by the local authority concerned. In the more progressive areas there is a high degree of differentiation

in treatment between the sick and mentally afflicted on the one hand, and the purely pauper class on the other—that is to say, between the hospital and the public assistance institution, formerly called the workhouse. The tendency in such areas has been to develop the hospital services on lines approximating to those obtaining in the voluntary hospitals.

In addition to the hospital appointments of the character mentioned, the Local Government Service offers numerous other (part-time) posts, such as those of public assistance medical officer and public vaccinator, which are commonly held by private practitioners. Domiciliary work in the public assistance medical service has been found, as the result of a recent inquiry, to be in many areas very inadequately recompensed, and in localities where unemployment is rife and increasing numbers of people are resorting to public assistance, the work is becoming more onerous. An assurance has been given by the Ministry of Health that where such increase of work is definitely proven, the local authority will be encouraged by the Ministry to listen to the plea for an increase of remuneration.

Enough has been said to show what variety of service, whole-time and part-time, institutional, and domiciliary, the Local Government Service offers, on the one hand, to the ambitious, who desire experience, and, on the other hand, to those who seek a secure position, with superannuation at the end.

PRISON MEDICAL SERVICE

Candidates for the prison medical staff are approved by the Secretary of State for the Home Office on the recommendation of the Prison Commissioners. Application for employment may be made to the Board on a special form, which can be obtained from the Secretary, Prison Commission, Home Office, London, S.W.1.

In the smaller prisons the medical officer is usually a local practitioner, but in the larger the members of the medical staff are required to devote their whole time to the service. In the case of those required to give their whole time to the post of medical officer Class I are instance is to the post of medical officer Class I are the seniors of this rank the medical officers Class I are selected as vacancies occur.

Largely as a result of action taken by the British Medical Association some years ago, the salaries of Civil Service bonus, now are: medical officer Class II, £505 7s., rising by annual increments to £725, medical officer Class I, £783 15s., rising by annual increments to £939 14s. Unfurnished quarters are provided, or an allowance in lieu is made.

There are 17 medical officers Class II, 12 medical officers Class I, and 26 part-time medical officers. The service is a small one, and therefore vacancies are comparatively rare and promotion is very slow. The work of a prison medical officer offers exceptional opportunities for research in criminal psychology, forensic psychiatry, and mental deficiency.

MEDICAL PRACTICE IN BRITISH DOMINIONS AND FOREIGN COUNTRIES

Medical Acts have now been passed in almost all places forming part of the British Empire beyond the seas, and registers of duly qualified practitioners are consequently maintained. To these registers medical men educated in the United Kingdom are generally admissible merely on payment of a registration fee, providing they produce evidence that they are of good repute and are either registered or eligible for registration in the United Kingdom, as the local requirement may be. The only exception to this statement that need be made relates to the Dominion of Canada. Each of its provinces has medical matters as an independent State. The result has been that reciprocity of practice has in the past been established between this country and each of the provinces

of Canada except British Columbia, where certain obstacles were never overcome. It has, however, to be recorded that reciprocity no longer exists with Saskatchewan, New Brunswick, Ontario, and Quebec. - We would advise any medical man proposing to practise in Canada first to communicate with the Provincial Registrar, stating what degrees or diplomas he holds, and asking for information as to the precise steps he must take in order to obtain admission to the Provincial Register. The Licence of the Dominion Council, which can only be obtained after examination, entitles its holder to registration in any of the provinces of Canada, though in regard to Quebec there is a proviso that "he must have been registered in the province five years prior to the application for the recognition of the Dominion Licence." In order to sit for the examination for the Dominion Licence, it is necessary to obtain either a licence from one of the provinces (this can be obtained from one of those with whom reciprocity has been established), or a certificate from a Provincial Council that the requirements of that Council in regard to preliminary education, matriculation, medical curriculum, and graduation have been complied with.

Italy and Japan are the only two foreign States with which complete medical reciprocity has been established, though there are other countries which grant a limited recognition to British qualifications. Generally speaking, in Continental countries (with the exception of the kingdom of Italy) a British medical man desiring to exercise his profession therein must pass practically the same examinations as those imposed on natives of the country. In France naturalization is now required also. The same observation applies to all foreign States in the South American continent. Each of the United States of North America has its own laws and regulations governing medical practice; and all of them require the holder of a British qualification to submit to an examination. A number of the States, including New York, Illinois, Michigan, and Indiana, require naturalization.

A pamphlet showing the conditions under which medical and dental practitioners legally qualified in their own country may practise abroad can be obtained from the offices of the General Medical Council, 44, Hallam Street, Portland Place, London, W.1, price 2s. 6d., or 2s. 9d. post free in the United Kingdom. Practitioners who think of going abroad to practise will find therein much useful information, including the name of the official in each country to whom requests for further particulars should be addressed. A new edition was published in 1933.

THE COLONIAL MEDICAL SERVICE

The Colonial Medical Service consists of the Medical Services in Bahamas, Barbados, Bermuda, British Guiana, British Honduras, Ceylon, Cyprus, Falkland Islands, Fiji, Gambia, Gibraltar, Gold Coast, Hong-Kong, Jamaica, Kenya, Leeward Islands, Malaya, Mauritius, Nigeria, Northern Rhodesia, Nyasaland, Palestine, St. Helena, Seychelles, Sierra Leone, Somaliland, Tanganyika, Trinidad, Uganda, Western Pacific (Gilbert and Ellice Islands, and British Solomon Islands), Windward Islands, and Zanzibar.

New entrants to the Service will be liable to transfer to any scheduled post therein whether or not such transfer represents promotion, provided that:

(a) No officer whose first appointment is to an office in a Dependency in which he was ordinarily resident at the time of appointment shall be liable to be transferred to an office outside that Dependency unless and until he shall have accepted an office in another Dependency.

(b) No officer shall be transferred without his own consent to an office which in the opinion of the Secretary of State is of less value (due regard being had to climate and other circumstances) than that which he already holds.

Officers who do not hold scheduled posts are eligible to apply for transfer to such posts. Appointment, confirmation, promotion, retirement, and transfer of M.O.'s

will be governed by the directions of the Secretary of State.

No officer of the Service is entitled, as of right, to private practice, the Service being envisaged as essentially a Service of whole-time officials whose primary duty is to the State.

The possession of a qualification registrable by the General Medical Council is a condition of eligibility for admission to the Colonial Medical Service.

Medical appointments in the self-governing Dominions and the territories under their control, and in Southern Rhodesia and Malta, are made by the Governments concerned, and are not in general open to candidates in the United Kingdom. In the Bahamas, Barbados, Bermuda, Ceylon, Jamaica, and Mauritius vacancies are practically always filled by the appointment of qualified local candidates or, in the case of some of the higher posts, by transfer from other colonies. Appointments to the medical services of the remaining colonies and other territories under the administrative direction of the Colonial Office are made by the Secretary of State for the Colonies in this country.

Conditions of service and superannuation are in the main determined by the economic resources and general public health policy of the individual colony and its local government, and vary almost as widely as do conditions of climate. Moreover, the extent of the control exercised by the Colonial Office varies according to the constitutional status of the particular colony, and the detailed information available centrally is not always complete. The intending candidate, therefore, should make comprehensive inquiries as to local conditions, and particularly as to facilities for private practice where this is precluded by the terms of appointment. He will also do well to supplement official information by reference to the Medical Secretary at the Central Office of the British Medical Association (Tavistock Square, London, W.C.1), where reports obtained from time to time from the local Branches are available.

To those physically and mentally suited to the climatic and social conditions peculiar to the various colonies the Colonial Medical Service should, and in most cases does, offer a field of professional activity rich in interest and in opportunity for pioneer work, with increasing facilities for specialization and research.

In view of the financial stringency from which Colonial Administrations are suffering, in common with Government and other authorities, it has been necessary, in some instances, to modify the terms and conditions of service, and whilst the unreduced emoluments, allowances, etc., are stated in this article, the fact that temporary reductions are in operation in many branches of the Service must be borne in mind, and intending applicants should satisfy themselves on this point before signing any agreement of service. In most colonies establishments have been reduced, and this entails a considerable reduction in the number of possible vacancies and affects materially the prospect of promotion.

Apart from immediate economic stringency, the outlook for the Colonial Medical Service is in the main a hopeful one, and especially so in the larger and better organized branches. The necessity, however, remains for making careful and sufficient inquiry as to the position in any branch of the Service before accepting appointment.

The medical services recruited in this country by the Secretary of State for the Colonies include those of West Africa, East Africa, Malaya, Hong-Kong, the West Indies, Fiji and the Western Pacific territories, and Palestine, besides a number of smaller services offering individually one or two appointments.

In Fiji, although the basic salary of district medical officers (£500, by £25 to £725) is below the £600 minimum recommended as adequate by the British Medical Association, this fact is offset by the concession of allowances of from £175 to £275 in some of the districts, the value of private practice in the other districts being estimated at from £100 to £600 a year. (Temporary reductions are in operation.)

The services in the West Indies and some of the smaller colonies have not yet conceded the £600 minimum commencing salary, and whilst facilities for remunerative private practice, general conditions of service, and a relatively low cost of living must in some instances be taken into consideration, these compensations are by no means universal. The service in the Leeward Islands is in a condition which requires special notice by way of warning. The position in Grenada has been improved, though such improvements have not extended to St. Lucia and St. Vincent. (Temporary reductions are in operation.)

In general, candidates for the Colonial Medical Service must be between the ages of 23 and 35. Appointments are, subject to a varying period of probation, for the most part classed as permanent and pensionable, but there are some appointments by agreement for a specified limited term of service. There is no entrance examination, but practitioners selected for appointment must obtain a certificate of physical fitness from one of the consulting physicians to the Colonial Office. Post-graduate experience in hospital appointments is desirable, and in a few cases special allowances are conceded to the holders of a D.P.H. Successful candidates are normally required to undergo an approved course of instruction in tropical medicine, the fees for their tuition being defrayed by the Government and an allowance being paid during their instruction.

Some thirty medical women are employed in child welfare, maternity, and laboratory work, mainly in the larger services—for example, those in East and West Africa and Malaya. Salaries are the same as for men.

The bulk of the appointments made by the Secretary of State in this country are to East and West Africa and Malaya.

West Africa

This is one of the best organized and best paid branches of the Service, and includes Nigeria, the Gold Coast, Sierra Leone, and the Gambia. Climatic conditions vary considerably over this area, but they are in general admittedly trying. This fact is at present recognized by the provision of more frequent leave periods than are usual elsewhere.

The service includes medical, public health, and laboratory divisions, and specialist posts are almost invariably filled by promotion from the staff. The rate of pay for a medical officer is £660 on appointment, rising by annual increments to £960, together with a seniority allowance of £72 a year after reaching £720, but temporary reductions are in operation. There are a considerable number of specialist and administrative posts carrying relatively high salaries, varying from £1,300, with duty allowance of £260, to £1,800, with duty allowance of £360. All appointments in the staff are pensionable. Officers may retire voluntarily on reaching 50 years of age, and may be called upon to retire at 55. Pensions of existing officers are calculated at the rate of 1/480th of the officer's pensionable emoluments (salary and house allowance) in respect of each complete month of service, but for new entrants the basis of calculation is 1/600th. The pension may be converted into a reduced pension of three-quarters of the full pension, with a gratuity of ten times the amount of the reduction. Gratuities of £1,000 or £1,250 may be drawn on retirement after nine or twelve years' service. Members of the Service in West Africa are not usually permitted to take their wives or young children with them until they have acquired experience of the conditions of life and have obtained the sanction of the Governor. In the case of young children this is only exceptionally given.

African Medical Officers

A number of Government appointments for African medical officers exist in the West African Colonies. These appointments carry salary on the scale £500-£225-£600, and there are higher scales of £600-£30-£720, and £740-£820.

East Africa

This branch of the Service includes Kenya, Uganda, Tanganyika Territory, Nyasaland, Zanzibar, and British Somaliland. In East Africa there is a very wide scope for clinical work, both medical and surgical, as well as for research and for preventive medicine and sanitation. In most stations conditions allow a medical officer's wife to accompany him, but this is not generally desirable on first appointment. In some Dependencies the consent of the Governor must be obtained. The service includes a medical and a sanitary division. The former is open to those holding ordinary medical and surgical qualifications, post-graduate experience in a hospital appointment being an advantage; posts in the sanitary division will as far as possible be filled by those holding a Diploma in Public Health or a Diploma in Tropical Medicine and Hygiene. Climatic conditions vary considerably. In a considerable part of Kenya they approximate more to the temperate than to the tropical zone; but there are some areas in the East African Dependencies where conditions more closely resemble those in West Africa. The rate of pay for a medical officer is from £600 on appointment, rising by annual increments of £30 to £840, and thereafter, subject to an efficiency bar at this point, by £40 to £920. Holders of the D.P.H. receive a special concession of two increments on appointment, or from the date of obtaining the diploma. (Temporary reductions are in operation, and in Kenya and Tanganyika the payment of fees to medical officers for conducting post-mortem examinations has been suspended.)

The gratuities available on retirement after nine or twelve years' service are similar to those in West Africa. Officers may elect or may be required to retire on pension on reaching the age of 50 years. Pensions of existing officers are calculated at the rate of 1/480th of emoluments (including value of free quarters) for each completed month of service, but for new entrants the basis of calculation is 1/600th. The officer of twenty-five years' service who has reached the maximum of the long scale receives a pension of approximately £650 per annum. Pensions are convertible, under certain conditions, into a reduced pension and a gratuity.

Malaya

This branch of the Service covers the Straits Settlements, the Federated Malay States, the Unfederated Malay States, and the State of Brunei in Borneo. The salary of \$500 a month, with an annual increment of \$25, rising to \$800 at the top of the time-scale (\$1 is fixed at 2s. 4d.), is generally considered adequate in view of the present cost of living, which is somewhat higher than that in England. The officer of twenty-five years' service, even if he has not held a senior appointment carrying a salary above the maximum of the time-scale, receives a pension of approximately £560 per annum. Pensions are convertible under certain conditions into a reduced pension and gratuity.

The climate of Malaya is, for the Tropics, a healthy one. It varies little throughout the year. The average rainfall is about 100 inches a year, and vegetation is always green. People who lead regular active lives have no difficulty in keeping in good health. European children do well in Malaya up to the age of about 6.

The professional duties of a medical officer may include medical, surgical, medico-legal, and public health work. His administrative work comprises hospital administration, diets, returns, and financial work, and includes the inspection of smaller hospitals and dispensaries. Districts vary in size, and a certain amount of travelling is necessary. The white population in each district varies. The district hospitals hold from 50 to 300 beds. There is a staff of locally recruited men, mostly trained at the Singapore College of Medicine. Asiatic dressers and trained hospital assistants are employed in hospitals and dispensaries. In addition to European sisters, there is a local nursing staff. All hospital equipment is supplied by Government, includ-

ing instruments. At both the Institute for Medical Research in Kuala Lumpur, Federated Malay States, and the King Edward VII College of Medicine, Singapore, there are opportunities for research as well as for routine investigations. In addition to the full-time professional posts at the College of Medicine several of the medical staff in Singapore hold part-time lectureships.

Sudan Medical Service

This Service is a department of the Sudan Government, and includes a number of Syrian and Sudanese medical officers and Sudanese assistant medical officers. The British medical inspectors are from the outset senior to all medical officers. The Service offers ample opportunities for specialization and for research, as well as for general, medical, and surgical work.

The climate varies, but is not in general unfavourable, though hot. In the northern desert the nights are cool, even in summer, and the winter is pleasant and often cold. In the central zone there is a rainy season of about four months, during which large areas become malarious. The south is more tropical in character, and mosquito-protected houses, nets, and protective quinine are essential during the greater part of the year, though even here the winter months are cool and pleasant. It is not considered desirable for medical inspectors to be accompanied by their wives until they have gained some knowledge of the language and the general conditions of life.

The commencing pay of a medical inspector is £E.720. On confirmation of appointment and success in the requisite examinations in Arabic the salary is increased by periodic increments to £E.1,200. Four senior administrative posts carry higher salaries. There is a compulsory contribution of 5 per cent. of pay towards pension, which, for a medical inspector, amounts, after twenty years' service, to £E.500 a year. All salaries are subject to an abatement of $7\frac{1}{2}$ per cent. owing to world depression. An officer who is compulsorily retired before completing fifteen years' service is not entitled to pension, but receives a gratuity.

Official Sources of Information

All inquiries in connexion with medical appointments in the self-governing Dominions and their Dependencies should be addressed to the High Commissioners or Agents-General for the Dominions. Intending applicants are also recommended to consult the Dominions Office and Colonial Office List, which may be seen at the Colonial Office Library or at the Library of the British Medical Association if not otherwise available, and the Professional Handbook, Part III (price 4d.), issued by the Oversea Settlement Department, Dominions Office, Caxton House, Tothill Street, London, S.W.1.

The position in Egypt is uncertain; questions as to the possibility of any medical appointments becoming available under the Egyptian Government should be addressed to the Director-General, Public Health Department, Cairo.

Inquiries as to vacancies and conditions in the Sudan Medical Service should be addressed in the first instance to Dr. Hodson, 24, Welbeck Street, London, W.1.

All inquiries in connexion with Colonial medical appointments made by the Secretary of State for the Colonies, or such vacancies as may occur in Palestine, should be addressed to the Director of Recruitment (Colonial Service), Colonial Office, 2, Richmond Terrace, Whitehall, London, S.W.1.

There remain a number of medical appointments made by mining companies and other commercial undertakings in various parts of the Tropics. Much caution should be exercised in accepting such posts, and the form of contract should be subjected to very careful scrutiny. Advice in this connexion should always be sought from the Medical Secretary of the British Medical Association, British Medical Association House, Tavistock Square, London, W.C.1.

SPECIAL DIPLOMAS

Information about the regulations for the various Diplomas in Tropical Medicine, in Psychological Medicine, and in Public Health is given in the appropriate sections of this Educational Number at pages 432-6 and 438. Further details in regard to the D.P.H. and the D.T.M. will be found in the late Sir Andrew Balfour's *Guide to the Regulations, Courses, and Examinations for Qualifications in Public Health and Tropical Medicine*, published by the British Medical Association, Tavistock Square, W.C.1, at the price of 3s.

It should perhaps be noted here that of the various diplomas in special subjects granted by licensing bodies only those in Public Health and Sanitary Science and State Medicine are at present admissible for entry in the official *Medical Register*, though other special diplomas may, of course, be included among the particulars of qualifications set out in the *Medical Directory*.

As stated at page 401 a Diploma in Tuberculous Diseases is granted by the University of Wales to qualified medical practitioners; new regulations for this diploma are now in force.

Diplomas in Medical Radiology

Diplomas in Medical Radiology are granted by the Universities of Cambridge, Edinburgh, Liverpool, and London.

The Cambridge Diploma.—A Diploma in Medical Radiology and Electrolgy is granted by the University of Cambridge. The primary object is to provide adequate training in a branch of medical work which is becoming increasingly important and difficult, and which is outside the ordinary medical curriculum. Before admission to any course for the diploma a candidate shall produce evidence that he holds a medical qualification approved by the committee and also satisfy the committee that he has had sufficient post-graduate clinical experience. The next course, which begins on October 3rd, 1934, occupies nine months. The first four months, which can be spent either in Cambridge or in London, are occupied with (a) lectures and practical work in physics, in preparation for the examination for Part I in February, (b) an introductory course of clinical instruction in radiology and electrolgy, (c) a course of instruction in pathology in relation to radiology and electrolgy. The next three months must be spent in London, and are occupied with (a) lectures and demonstrations in radiology and electrolgy (including radium therapy) organized by the British Institute of Radiology, (b) clinical instruction in the radiological department of a hospital approved by the committee. During the final two months of the course a candidate must hold a clinical clerkship or similar appointment in the radiological department of a hospital approved by the committee. This part of the course may be done in London or elsewhere. The examination for Part II will be held in July.

Further particulars as to courses and examinations may be obtained from G. Stead, M.A., Secretary for the Diploma, Cavendish Laboratory, Cambridge, or the General Secretary, British Institute of Radiology, 32, Welbeck Street, W.1. Completed application forms must be sent to the Secretary for the Diploma at Cambridge.

The Edinburgh Diploma.—Candidates for the diploma must be graduates in medicine and surgery of the University of Edinburgh, or hold corresponding degrees or qualifications registrable with the General Medical Council of Great Britain, or of such other Universities or Medical Schools as may be recognized for the purpose by the University Court. Candidates are not admitted to the examination for the diploma until after the lapse of not less than one year from obtaining a registrable qualification. The course of study begins in October and extends over a period of not less than three terms. The examination, which is written, oral, and practical, is in two parts: (a) physics, and (b) radiology. The examination is

held twice yearly. Full particulars may be obtained from the Dean of the Faculty of Medicine. In this connexion it may be noted that radiology can now be taken as the special subject in the examination for Membership of the Royal College of Physicians of Edinburgh. Several candidates have already taken radiology as their special subject; it means that an honours standard has to be attained.

The Liverpool Diploma.—The University of Liverpool grants a Diploma in Medical Radiology and Electrology. Candidates before admission to the examination for the diploma must possess a registrable qualification approved by the university in medicine and surgery, and must have attended courses of instruction in (a) physics (two terms); (b) (i) radiology and (ii) electrology, during the nine months in the x-ray and electrotherapeutic departments of a hospital or hospitals. An examination is held in March and June in physics, in June radiology and electrology. Examination in either part may be taken separately. Fees: tuition, £31 10s.; examination and diploma, £6 5s. A registration deposit fee of £5 5s. is charged on application and credited to the fees, but is not returnable in the event of the candidate failing to register. These courses commence during the first week in October. Application should be made to the Dean, Faculty of Medicine, the University of Liverpool.

Conjoint Diploma in Medical Radiology.—Regulations have now been issued for the Diploma in Medical Radiology (D.M.R. R.C.P. and S.Eng.) which has recently been instituted by the Royal College of Physicians of London and the Royal College of Surgeons of England. The examination is divided into two parts, the first comprising physics as applied to radiology, the second medical radiology, with special reference to its clinical application, including radio-diagnosis, x-ray therapy, and radium therapy. Both parts will be held in January and July of each year. Candidates may enter for them either together or separately, subject to the production of the required certificates. The course for the diploma extends over one academic year (nine months) of full-time study subsequent to the attainment of a recognized medical qualification. At the discretion of the committee of management the conditions of admission may be modified in special cases, but exemption will not be granted from any part of the examination. A syllabus has been drawn up for Part I of the examination, but not for Part II. The fee for admission or readmission to each part is six guineas. Copies of the regulations may be obtained from the secretary, at the Examination Hall, S-11, Queen Square, W.C.1.

The London Diploma.—The University grants an Academic Diploma in Medical Radiology. The course is open to registered medical practitioners and graduates in medicine of this or another approved university. Students are required to attend a course of study approved by the University, and extending over not less than one academic year, at one or more of the Colleges or Schools of the University. The subjects of the course are as follows: Part I: physics and electro-technology. Part II: (a) radiography and radio-diagnosis; (b) radiotherapy. The examination for the Academic Diploma in Medical Radiology consists of two parts. Candidates may enter for Part I and Part II at the same examination, or may enter for Part I only. The examination will consist of a paper, a practical examination, and an oral examination in each of the subjects under Part I and Part II. Full particulars may be obtained from the Academic Registrar, University of London, South Kensington, S.W.7.

Diploma in Laryngology and Otology

The Conjoint Examining Board in England (Examination Hall, Queen Square, London, W.C.1) grants a Diploma in Laryngology and Otology (D.L.O.) after an examination held in June and December. The examination comprises two parts: Part I. on the anatomy, embryology, and physiology of the ear, nose, pharynx, larynx, trachea and bronchi, and oesophagus; Part II, on the recognition and use of special instruments and

appliances, and the medicine, surgery, and pathology of these regions. Candidates may enter for Part I at any time after a recognized qualification in medicine, surgery, and midwifery has been obtained. Candidates may enter for Part II on completion of one year of special study of diseases of the ear, nose, pharynx, and larynx, after a recognized qualification has been obtained, provided that Part I has been previously passed, and on production of certain certificates. The conditions of study may be modified at the discretion of the Committee of Management in special cases. The fee for admission or readmission to each part is six guineas.

Diplomas in Ophthalmic Medicine

A special Diploma in Ophthalmic Medicine and Surgery is granted by the University of Oxford and by the Conjoint Examining Board in England.

University of Oxford.—For the Diploma in Ophthalmology (D.O.) attendance on a twelve months' course of clinical ophthalmology in hospitals or institutions recognized for the purpose by the Board of the Faculty of Medicine, and on a course of instruction in Oxford lasting two months, is obligatory. Candidates must have their names on the *Medical Register* of the United Kingdom, unless, being Bachelors or Doctors of Medicine of universities outside the United Kingdom, they have obtained special permission from the Board of the Faculty of Medicine.

The Conjoint Board.—The Diploma in Ophthalmic Medicine and Surgery of the Conjoint Examining Board of the Royal College of Physicians of London and Royal College of Surgeons of England is issued after completion of an examination held in two parts—in January and July. The examination in each case is partly written, partly oral, partly clinical or practical. Part I comprises anatomy and embryology of the visual apparatus, physiology of vision, elementary optics; Part II comprises optical defects of the eye, ophthalmic medicine and surgery, pathology with special reference to medical and surgical ophthalmology. Candidates may enter for Part I at any time after a recognized qualification in medicine, surgery, and midwifery has been obtained. Candidates may enter for Part II on completion of one year of special study of ophthalmology after a recognized qualification has been obtained, provided that Part I has been previously passed, and on production of certain certificates. The conditions of study may be modified at the discretion of the Committee of Management in special cases. The fee for admission or readmission to each part is six guineas.

Diplomas in Obstetrics

The Society of Apothecaries of London, as stated on page 402, confers a Mastery of Midwifery, and issues a diploma under this title denoting the possession of specialized knowledge of ante-natal care, midwifery, and child welfare. This is a post-graduate diploma, and is not registrable under the Medical Acts. The same applies also to the new diploma D.C.O.G., which the British College of Obstetricians and Gynaecologists now issues to registered medical practitioners who have had special post-graduate training and experience in the subject and have satisfied the examiners. (See p. 403.)

The Conjoint Examining Board in England, according to the new regulations for its Diploma in Gynaecology and Obstetrics (D.G.O. R.C.P. and S.Eng.), will hold examinations in April and October. Those eligible for admission to examination must have held a degree in medicine and surgery recognized by the Board, or a qualification registrable in this country, for not less than three years. The subjects of the examination are gynaecology and obstetrics (including pathology, histology, and bacteriology in relation to these subjects), and ante-natal, post-natal, and infant welfare work. The examination is written, oral, and clinical, but only those candidates are admitted to the clinical who satisfy the examiners in the written and oral. A form is issued on which particulars

have to be given and certified as to resident appointments in the gynaecological and obstetrical department of a recognized general hospital, in a gynaecological hospital, or a maternity hospital, or as to registrarship or clinical assistantship held in such institutions, together with particulars as to regular attendance, with responsible care of patients, at recognized ante-natal, post-natal, and infant welfare clinics during twelve months. It is added that these conditions of study may be modified in the case of a candidate who has carried out original investigations or written a thesis on some subject in gynaecology or obstetrics, or whose studies have extended over a prolonged time without fulfilling the exact conditions set out; but exemption will not be granted from any part of the examination. The fee for admission to examination or re-examination is ten guineas. Copies of the regulations for this diploma may be obtained from the Secretary, Examination Hall, Queen Square, W.C.1.

University of Lausanne

M.D. Examination for Medical Practitioners

It has been possible for a long time to obtain the M.D. degree (not registrable in this country) from one of the State Universities in Switzerland—namely, Berne, Geneva, and Lausanne. The regulations of the Faculty of Medicine of the University of Lausanne have recently been drastically revised by the authorities, and in October, 1930, new regulations came into force, the main effect of which is to provide a special M.D. examination for medical practitioners from other countries. Particulars may be obtained from Dr. C. A. H. Franklyn, honorary secretary, Lausanne Medical Graduates, The Corner House, 34, Queensway, Wragby Road, Lincoln (booklet and copy of regulations, post free, 2s. 1½d.).

MEDICAL MISSIONARIES

Missionary societies are in constant need of qualified men and women to fill vacancies as they occur in their hospitals, and also to enable them to take advantage of fresh openings. To those suitably endowed the mission field offers unique opportunities for interesting work, and the development of native medical schools, as training institutions in connexion with some of the larger mission hospitals, affords excellent scope for valuable work to medical men and women who are qualified to teach. It is not usually expected that medical missionaries should take a position such as would otherwise be occupied by an ordained clergyman or minister, but it is essential that they should be prepared to exert their influence in any hospital to which they may be sent, so that a Christian atmosphere may be maintained and the work of evangelization be carried on through the ministry of healing.

As for scientific and other qualifications for the work, medical missionaries, in addition to being physically capable of sustaining a life which makes a great demand upon their strength, should be thoroughly well-trained physicians and surgeons. It is very desirable that they should have held a resident appointment at a general hospital, and have a good knowledge of practical surgery, gynaecology, tropical medicine, and the treatment of eye diseases. Useful information can be obtained from the secretaries of the various Missionary Societies, or from Thomas B. Adam, Honorary Secretary, Medical Advisory Board on Medical Missions to the Conference of Missionary Societies in Great Britain and Ireland, The Crossways, 45, Kenton Road, Harrow, Middlesex, or 19, Farnival Street, E.C.4.

Dental Surgery

Until the passing of the Dentists Act, 1921, the profession of dentistry in this country was regulated by enactments corresponding very closely with those relating to the practice of medicine—that is to say, there was no direct prohibition of the act of practice; and the Dentists Act of 1878 gave the same degree of protection to legally qualified and registered dentists as was accorded to registered medical practitioners—namely, the reservation of the use

of certain titles. This Act provided also (1) that no person should take or use the name or title of "dentist" (either alone or in combination with any other word or words) or of "dental practitioner," or any other name, title, or description expressed in words or by letters implying that he was specially qualified to practise dentistry, unless he was registered, under a penalty of £20; and (2) that an unregistered person could not recover any fee or charge in respect of any dental operation, attendance, or advice. But, in the case of the practice of medicine by unqualified and unregistered persons, certain deterrent factors came into play—such as the inability to give a death certificate—which did not operate to the same extent in the case of dentistry; hence, unqualified practice was far more prevalent in dentistry than in medicine, and increased after a decision of the House of Lords placing a narrow interpretation upon the words "specially qualified to practise dentistry," by defining the word "qualified" as not referring to competence but to the possession of a recognized diploma.

Dentists Act, 1921

This unsatisfactory position was remedied by the passing into law of the Dentists Act, 1921; its provisions are based largely on the recommendations of a departmental committee appointed in 1917 by the Privy Council "to investigate the extent and gravity of the evils connected with the practice of dentistry and dental surgery by persons not qualified under the Dentists Act." Since November 30th, 1922, no person has been permitted by law to practise or hold himself out, whether directly or by implication, as practising or as being prepared to practise dentistry unless he is on the *Dentists Register* kept under the Dentists Act, 1878. The practice of dentistry is defined as including "the performance of any such operation and the giving of any such treatment, advice, or attendance, as is usually performed or given by dentists," and the performing of any operation or the giving of any "treatment, advice, or attendance on or to any person as preparatory to or for the purpose of or in connexion with the fitting, insertion, or fixing of artificial teeth." The maximum penalty incurred by an unregistered practitioner is £100 for each offence. There are, however, certain important exceptions to the requirement of registration. A registered medical practitioner may practise dentistry without being on the *Dentists Register*, though he may not give dental treatment to insured persons under the National Health Insurance Acts unless he be so registered. A registered pharmaceutical chemist or chemist and druggist may extract a tooth where the case is urgent and where no doctor or dentist is available, but the operation must be performed without any kind of anaesthetic; and minor dental work may be performed in a public dental service under the personal supervision of a registered dentist provided it is in accordance with conditions approved by the Minister of Health after consultation with the Dental Board.

Dentistry may be carried on by a corporate body provided that the majority of the directors and all the operating staff are registered dentists, and that no business other than dentistry or only some business ancillary to dentistry is carried on by the company. Companies carrying on the business of dentistry at the present time are permitted to continue to do so with certain restrictions, provided that the name of the company as well as the names of the directors have been entered in a list kept under the Act for that purpose. Every director or manager of a company convicted of an offence under the Act will be held to be guilty of the offence unless he proves that the offence was committed without his knowledge, and the court may, in addition to a fine, order that the name of any director convicted shall be removed from the list of directors aforesaid.

The Dental Board

On the establishment of the Dental Board in 1921, certain powers and duties of the General Medical Council were transferred to it, including the duty of erasing from the *Dentists Register* any entry which has been incorrectly or fraudulently made. An inquiry into the case of a person alleged to be liable to have his name erased from the *Register* is made by the Board, which reports its findings

to the General Medical Council, the order directing the erasure being made by the Council. A name erased from the Register can only be restored by the Council upon a report made by the Board. An appeal to the High Court may be made by any person aggrieved either by refusal of the Board to register his name or by the removal of his name from the Register. The administrative expenses of the Board are defrayed from the registration fees and annual retention fees, but any surplus may be allocated to purposes connected with dental education and research or to any public purposes connected with the profession of dentistry. The offices of the Dental Board are at 44, Hallam Street, London, W.1.

Dental Education and Examination

The preliminary examination in arts is the same for medical and dental students, and the early stages of their education embrace much the same subjects¹; and, as the dental student is required to obtain a knowledge of the broad principles of medicine and surgery, it is necessary for him to pursue some portion of his studies at a medical school as well as at a special dental school, the latter not undertaking the teaching of these subjects. Registration as a dental student is not in all cases compulsory, though it is to be advised as convenient as affording proof of the date at which professional education began, and is required by most of the licensing bodies, all of whom insist upon a curriculum covering four academic years.

Degrees and diplomas in dentistry are granted by the Universities of Belfast, Birmingham, Bristol, Dublin, Durham, Leeds, Liverpool, London, Manchester, St. Andrews, Sheffield, and the National University of Ireland, as will be found stated in the articles on these universities. Licences in dentistry entitling the holder to be registered on the *Dentists Register* are granted by the Royal Colleges of Surgeons of England, of Edinburgh, and in Ireland, and by the Royal Faculty of Physicians and Surgeons of Glasgow. Recognized dental schools are numerous. In London there are those connected with the Royal Dental Hospital, Leicester Square; the National Dental Hospital, Leicester College Hospital (Dental School), Great Portland Street; Guv's Hospital; King's College Hospital; and the London Hospital. In the provinces there are the Birmingham Dental Hospital; the Royal Infirmary and the General Dispensary, Bristol; the Dental Hospital and the Public Dispensary, Leeds; the Dental Hospital, Liverpool; the Dental Hospital, Manchester; the Sutherland School, Newcastle-on-Tyne; the Royal Dental Hospital, Sheffield. In Scotland there are the Dental Hospital, Dundee; the Incorporated Dental Hospital and School, Edinburgh; and the Incorporated Dental Hospital, Glasgow; and in Ireland, the Belfast Dental School, the Incorporated Dental Hospital of Ireland, Dublin, and the Royal College of Surgeons in Ireland, Dublin.

All who think of becoming dentists may be advised to study a memorandum, drawn up for their guidance on behalf of the Board, setting out in convenient form and in untechnical language information for which the Board is often asked.² It will be seen from this pamphlet that in order to assist suitable students the Board has instituted a system of bursaries to pay the fees of those who have not the financial means to qualify, and in exceptional cases maintenance may also be given as well.

General Medical Council's Recommendations

The Dentists Act still leaves to the General Medical Council the duty of controlling the course of study and examinations required for dental qualifications. Recommendations as to the course of study and examinations to be required of candidates for degrees or licences in dentistry or dental surgery were adopted by the Council this year, and come into force on October 2nd, 1933. We print them below in a somewhat abridged form.

¹ See the Memorandum on Students' Registration printed in the article in the General Medical Council at page 393.
² Memorandum on the Procedure to be Adopted by Those who Desire to Enter the Profession of Dentistry, with Notes on Costs and Prospects 1933. Dental Board of the United Kingdom, 44, Hallam Street, W.1. Price 1s post free.

Preliminary Examination and Registration

Every dental student should, at the beginning of his studentship, be registered in the manner and under the conditions prescribed for medical students. Before registration in the *Dental Students' Register* every applicant should be required to have passed, in addition to the examination in general education, which shall be the same as that required for medical students, an examination in elementary physics and chemistry, conducted or recognized by one of the licensing bodies, which shall also be the same as that required for medical students. Before registration as a dental student every applicant should produce evidence that he has attained the age of 17 years.

Professional Study

Every candidate for a degree or licence in dentistry or dental surgery should be required before admission to the final or qualifying examination to produce certificates showing:

- (i) That he is at least 21 years of age.
- (ii) That he has been registered as a dental student.
- (iii) That he has, subsequently to registration as a dental student, been engaged in professional study for at least four years, of which three years at least shall have been spent at a school or schools recognized for professional study by one of the licensing bodies.
- (iv) That, subsequently to registration as a dental student, he has attended at a recognized medical or dental school, courses of instruction which should be the same as those for medical students, in (a) chemistry, and (b) physics, in their application to medicine and dentistry. (c) Elementary biology. (A student who has diligently attended an approved course of elementary biology in a teaching institution recognized by a licensing body may be admitted to a professional examination in elementary biology immediately after his registration as a dental student.) That he has attended at a recognized medical school courses of instruction, specially adapted for students in dentistry, in the following subjects:
 - (d) human anatomy, including dissections for three academic terms of nine months. This should include not less than 40 lectures and/or demonstrations. The course of dissections shall include dissections of the head and neck, a practical course in chemical and/or demonstrations; also practical course of not less than 30 hours. (g) General pathology for two academic terms (not less than 40 lectures and/or demonstrations). (h) Bacteriology for one term (not less than 10 lectures and 24 hours' practical work). (i) Medicine for two academic terms or six months (not less than 30 meetings of the class). (j) Surgery for two academic terms or six months (not less than 40 meetings). (k) Clinical instruction in a recognized general hospital on selected cases with any bearing on dentistry. Each of these courses should consist of not less than 50 meetings. It is desirable that the systematic courses in medicine and surgery and the clinical course of instruction in medicine, surgery, and pathology should normally be taken after the student has passed the examinations in human anatomy and physiology.
 - (v) That he has attended at a recognized dental school comparative. The course should comprise a minimum of 20 meetings of the class. (b) Practical normal and morbid histology (16 meetings). (c) Dental surgery (20 meetings). (d) Materia medica and therapeutics (10 meetings). (e) Metalurgy with practical work and demonstrations (16 meetings). (f) Dental mechanics and prosthetics (20 meetings). (g) Instruction in the use of anaesthetics employed in the practice of dentistry. (h) Instruction in radiology and its application to dentistry. (i) The principles of orthodontics (10 meetings).
 - (vi) That he has for at least two calendar years attended the practice of a recognized dental hospital or of the dental department of a general hospital recognized by a licensing body as forming part of a dental school.
 - (vii) That he has received for not less than 24 calendar months, or for 2,000 hours, practical instruction in dental mechanics. No portion of such practical instruction in dental taken before registration shall be reckoned as a portion of the four years of professional study required, but in the event of hardship arising in a particular case, an application for exceptional treatment may be submitted to the Education Committee of the General Medical Council. It is recommended that practical instruction in dental mechanics shall be taken

POST-GRADUATE COURSES AND LECTURES

THE BRITISH
MEDICAL JOURNAL

at a recognized dental hospital and school. If any part of such instruction be taken by the candidate as a pupil with a registered dentist, the time devoted to it shall be at least twice the time required for the corresponding instruction taken at a dental school.

Professional Examinations

The examinations for a degree or licence in dentistry should be partly written, partly oral, and partly practical, and should include the following subjects: (a) Chemistry, Physics, and Biology in their bearing on medicine and dentistry. (b) Human anatomy, the oral examination in which should be conducted mainly on dissections, especially of the head and neck. (c) Physiology, the oral examination in which should include practical physiological tests. (d) Histology, which may be included in the examination in either anatomy or physiology. (e) General pathology, the oral examination in which should be conducted with the aid of specimens, including those of diseases connected with dentistry. (f) Bacteriology, the oral examination in which should include simple practical tests. (g) Medicine and surgery, the oral examinations in which should include a clinical examination of patients. (h) Special anatomy, human and comparative.

(i) Dental mechanics, prosthetics and metallurgy, including practical tests. (j) Dental surgery, including special pathology and histology, materia medica and therapeutics, and the principles of orthodontics. (k) Practical dental surgery, which should include the usual dental operations—for example, filling and extraction of teeth and the giving of anaesthetics—and a clinical examination on the diagnosis and treatment of dental disease and abnormal conditions of the oral cavity. A candidate should produce a certificate of having administered general anaesthetics on at least ten occasions.

ACKNOWLEDGEMENT

The detailed information published in this Educational Number of the *British Medical Journal* for the benefit of intending students of medicine and newly qualified practitioners has been revised throughout with the co-operation of the deans and secretaries of the medical schools and kindred institutions and of officials in the several public services, to all of whom we wish to acknowledge our indebtedness.

POST-GRADUATE COURSES AND LECTURES
SEPTEMBER AND OCTOBER, 1934

The following post-graduate courses and lectures to be held in London during September and October have been notified to the British Medical Association. Further particulars may be obtained direct from the hospital concerned, or, in the case of arrangements made by the Fellowship of Medicine (F.M.), from the Secretary of the Fellowship at 1, Wimpole Street, W.1.

Subject	Date	Place of Meeting	Nature of Instruction
Anaesthetics	From Sept. 1 to Sept. 24-29	West London Hosp. Post-Grad. College, Hammersmith Rd., W.6	Course
Chest Diseases	Sept. 3-15	Infants Hospital, Vincent Sq.	F.M. course
Children's Diseases	Sept. 17-29	Westminster Hospital, S.W.1	"
General ...	Sept. 4	11, Chandos Street, W.1	"
"	Sept. 11	"	"
"	Sept. 18	"	"
"	Sept. 25	"	"
Proctology...	Sept. 24-29	Gordon Hospital, Vauxhall	"
Urology ...	Sept. 8	National Temperance Hospital, Hampstead Rd., N.W.1	"
Anaesthetics	From Oct. 1 to Oct. 8-20	West London Hosp. Post-Grad. College, Hammersmith Rd., W.6	F.M. lecture-demonstration on pleural pain
Cardiology	Oct. 8-20	National Hospital for Heart Diseases, Westmoreland St., W.1	Ditto on chronic cough
Chest Diseases	Oct. 27-28	Brompton Hospital, Fulham Rd., S.W.3	Ditto on hemiplegia
Children's Diseases	Oct. 1-13	Queen's Hospital, Hackney	Ditto on paraplegia
"	Oct. 22-27	Hospital for Sick Children, Great Ormond Street, W.C.1	F.M. course
Dermatology	Oct. 1-27	St. John's Hospital, 49, Leicester Square, W.C.2	F.M. lecture-demonstration
General ...	Oct. 8-21	Metropolitan Hospital, Kingsland Road, E.8	Course
Gynaecology	Oct. 22-27	Chelsea Hospital for Women, S.W.3	F.M. course
Infectious Diseases	Oct.-Dec.	North-Eastern Fever Hospital, N.15	"
Medicine ...	Oct. 13	National Temperance Hospital, Hampstead Rd., N.W.1	Course in fever hospital administration*
"	Oct. 2	Medical Society of London, 11, Chandos St., W.1	F.M. lecture-demonstration
"	Oct. 9	"	Ditto on tremor
"	Oct. 16	"	"
"	Oct. 23	"	"
Neurology	Oct. 30	"	Ditto on ataxia
Ophthalmology	Oct. 29-30	"	Ditto on giddiness
Pathology ...	Oct. 15-16	West End Hospital for Nervous Diseases, 73, Welbeck St., W.1	Ditto on convulsions
Physical Medicine	Oct. 8-15	Royal Westminster Ophthalmic Hospital, W.C.2	Ditto on headache
Psychotherapy	Oct. 1-27	Great Ormond Street, W.C.1	F.M. course
Surgery ...	From Oct. 1 to Oct. 20-21	Institute of Medical Psychology, 6, Torrington Place, W.C.1	Course
		Royal Albert Dock Hospital	F.M. course of clinical surgery

Courses in general hospital practice may be begun at any time, and may be taken for any period, at the West London Hospital Post-Graduate College, Hammersmith Road, W.6. In addition to the above courses the following for the higher qualifications have been arranged.

Subject	Date	Place of Meeting	Degree or Diploma
Medicine ...	Sept.-Oct.	Guy's Hospital Medical School	M.R.C.P.
"	"	King's College Hospital Medical School	"
Pathology ...	Sept.	Middlesex Hospital Medical School	"
Surgery ...	Sept.	University College Hospital	"
"	From Sept. 3 to Sept. 10	St. Mary's Hospital Medical School	M.B., B.S.
"	"	Middlesex Hospital Medical School	Primary
"	Sept.-Nov.	Guy's Hospital Medical School	F.R.C.S.
"	From Sept. 1 to Sept. 10	St. Bartholomew's Medical College	"
"	Sept. 25-30	St. Thomas's Hospital Medical School	Primary and Final F.R.C.S.
"	Sept. 27-30	National Temperance Hospital	"
"	From Sept. 1 to Sept. 10	London Hospital Medical School	Final F.R.C.S. (F.M.)
"	From Sept. 1 to Sept. 10	Dreadnought Hospital, Greenwich	Final F.R.C.S.
"	From Sept. 1 to Sept. 10	King's College Hospital Medical School	"
"	From Sept. 1 to Sept. 10	University College Hospital	"
"	From Sept. 1 to Sept. 10	London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1	M.S. or F.R.C.S.
"	From Sept. 1 to Sept. 10	Central London Throat, Nose and Ear Hospital, Gray's Inn Road, W.C.1	Dip. Bact.
"	From Sept. 1 to Sept. 10	Royal Eye Hospital, St. George's Hospital, City Road, E.C.1	D.L.O.
"	From Sept. 1 to Sept. 10	Royal London Ophthalmic Hospital, City Road, E.C.1	D.O.M.S.
"	From Sept. 1 to Sept. 10	Tropical Medicine, Keppel Street, W.C.1	"
"	From Sept. 1 to Sept. 10	Royal Institute of Public Health, 23, Queen Sq., W.C.1	D.P.H.
"	From Sept. 1 to Sept. 10	Cancer Hospital, Fulham Rd., S.W.3	D.P.H.
"	From Sept. 1 to Sept. 10	King's College	D.M.R.
"	From Sept. 1 to Sept. 10	London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1	Primary
"	From Sept. 1 to Sept. 10	"	F.R.C.S.
"	From Sept. 1 to Sept. 10	"	D.T.M. and H.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—Infants Hospital, Vincent Square, S.W.1. All-day Course in Infants' Diseases. *Medical Society of London*, 11, Chandos Street, W.: Tues., 2.30 p.m., Lecture-Demonstration (illustrated by cases) by Dr. Clark-Kennedy on Some Practical Points in the Diagnosis and Treatment of Urological Cases, by Mr. H. P. Winsbury-White. *Panel of Teachers*: Individual clinics in various branches of medicine and surgery are available daily. Courses of instruction, clinics, etc., arranged by the Fellowship are open only to members and associates.

* Inquiries to be made to Medical Officer of Health, L.C.C., Public Health Department (Special Hospitals), Victoria Embankment, E.C.4.

Naval and Military Appointments

ROYAL NAVAL MEDICAL SERVICE

Surgeon Lieutenant Commander R. W. Mussen to be Surgeon Commander.

ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Lieutenants A. E. Williams to the Victory, for Royal Naval Barracks; W. Gough to the Effingham.

ROYAL AIR FORCE MEDICAL SERVICE

Flight Lieutenant O. M. Fraser to No. 1 Armament Training Camp, Catfoss.

Flying Officer W. P. Stamm to No. 2 Armament Training Camp, North Coates Fitties.

Diary of Central Meetings

SEPTEMBER

20 Thurs. Insurance Acts Committee, 11.30 a.m.

27 Thurs. Medical Students and Newly Qualified Practitioners Subcommittee, 3.30 p.m.

VACANCIES

ACTON HOSPITAL, W.—J.R.M.O. (male, unmarried).
ALL SAINTS' HOSPITAL FOR GENTO-URINARY DISEASES, Austral Street, S.E.—R.H.S. (male).

BARROW-IN-FURNESS: NORTH LONSDALE HOSPITAL.—R.C.O. (male).

BELFAST: FORSTER GREEN HOSPITAL FOR CONSUMPTION AND CHEST DISEASES.—H.P.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—R.S.O.

BOLINGBROKE HOSPITAL, Wandsworth Common, S.W.—R.M.O. (male).

BURY INFIRMARY, Lancs.—H.S. to Special Departments.

CAMBRIDGESHIRE COUNTY COUNCIL.—County M.O.H. (male).

CANCER HOSPITAL (FREE), Fulham Road, S.W.—H.S.

CHELTHAM GENERAL AND EYE HOSPITALS.—Hon. Pathologist.

COVENTRY AND WARWICKSHIRE HOSPITAL.—R.C.O. (male).

DEAL, WALSLEY, AND DISTRICT WAR MEMORIAL VICTORIA HOSPITAL.—Hon. P.

DURRY: DERRYSHIRE ROYAL INFIRMARY.—(1) H.S. for General Surgery and Ear, Throat, and Nose Department. (2) C.O. and Orthopaedic H.S. Devonport.

DEVONPORT ROYAL ALBERT HOSPITAL AND EYE INFIRMARY.—Assistant H.S. (unmarried).

DUNDEE AND DISTRICT GENERAL INFIRMARY.—(1) H.S. (2) Hon. Visiting Orthopaedic S.

DONCASTER ROYAL INFIRMARY AND DISPENSARY.—(1) Two Hon. Assistant S. (2) H.S. (male).

DONCASTER RURAL DISTRICT COUNCIL.—M.O.H.

EAST HAM MEMORIAL HOSPITAL, Shrewsbury Road, E.—(1) H.S. to Special Departments. (2) C.O. (male).

EXETER: ROYAL DEVON AND EXETER HOSPITAL.—(1) H.S. (2) H.S. to Ear, Nose, and Throat Department. Males.

FIVE DISTRICT ASYLUM.—A.M.O.

GREAT YARMOUTH GENERAL HOSPITAL.—H.S. (male, unmarried).

HARROGATE AND DISTRICT GENERAL HOSPITAL.—(1) H.P. and C.O. (2) H.S. Males, unmarried.

HAVE GENERAL HOSPITAL.—R.M.O. (male).

HULL ROYAL INFIRMARY.—Hon. Assistant P.

HULL AND SCULCOATES DISPENSARY.—R.M.O.

INSTITUTE OF RAY THERAPY AND ELECTRO-THERAPY, Camden Road, N.W.—Part-time M.O. (male).

KING'S LYNN: WEST NORFOLK AND KING'S LYNN GENERAL HOSPITAL.—R.S.O.

LANCASHIRE COUNTY COUNCIL.—J.H.S. at Biddulph Grange Orthopaedic Hospital.

LEAMINGTON SPA: WARNEFORD GENERAL HOSPITAL.—H.S. (male, unmarried) for Casualty and Special Departments (combined 10-1).

LEICESTER ROYAL INFIRMARY.—(1) Two H.S. (2) Two C.O. (3) H.P. (4) Two Junior Resident Anaesthetists.

LUTON: BUTE HOSPITAL.—H.S. (male).

MANCHESTER: ANCOATS HOSPITAL.—(1) Whole-time Assistant Pathologist. (2) R.M.O. (3) H.P. (4) Medical Registrar.

MANCHESTER AND SALFORD HOSPITAL FOR SKIN DISEASES.—H.S.

MANCHESTER CITY.—Second R.A.M.O. (unmarried) at Abergele Sanatorium, North Wales.

MANCHESTER: ROYAL MANCHESTER CHILDREN'S HOSPITAL.—Two A.M.O.s (non-resident) for Out-patients' Department.

MANCHESTER: ST. MARY'S HOSPITALS.—(1) Two H.S. at Whitworth Street West Hospital (Males). (2) Three H.S. at Whitworth Park Hospital (Two for Gynaecological and one for Children's Department).

MARGATE AND DISTRICT GENERAL HOSPITAL.—R.M.O. (male).

MARRET DRAYTON: CHESHIRE JOINT SANATORIUM.—R.A.M.O.

MIDDLESBROUGH: NORTH RIDING INFIRMARY.—Hon. S.

MIDDLESEX COUNTY COUNCIL.—J.A.R.M.O. at North Middlesex County Hospital.

NATIONAL TEMPERANCE HOSPITAL, Hampstead Road, N.W.—R.M.O. (male).

NEWCASTLE THROAT, NOSE, AND EAR HOSPITAL.—H.S.

NORTHAMPTON GENERAL HOSPITAL.—(1) H.P. (2) Two H.S. (3) H.S. to Ear, Nose, and Throat Department. (4) C.O. Males.

NORWICH: NORFOLK AND NORWICH HOSPITAL.—(1) C.O. and H.S. (2) H.S. to Special Departments (Ear, Nose, and Throat, and Ophthalmic). Males.

PETERBOROUGH CITY.—Clinic M.O. (male).

POOLE: CORNELIA AND EAST DORSET HOSPITAL.—H.S. (male, unmarried).

PRINCESS BEATRICE HOSPITAL, Earl's Court, S.W.—(1) R.M.O. (2) H.P. and C.O. (3) H.S. and C.O. Males.

QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road, E.—(1) H.P. (2) C.O. Radium Institute, Riding House Street, W.—H.S. (unmarried).

RICHMOND, SURREY: ROYAL HOSPITAL.—J.H.S. (male, unmarried).

ROYAL NAVAL DENTAL SERVICE.—Three Vacancies as Dental Officer.

ROYAL NORTHERN HOSPITAL, Holloway, N.—(1) H.S. (2) Obstetric H.S.

ST. BARTHOLOMEW'S HOSPITAL, E.C.—Whole-time Registrar in Cancer Department.

ST. MARY'S HOSPITAL, W.—Part-time Assistant Director of Venereal Diseases Department.

ST. PETER'S HOSPITAL FOR STONE, ETC., Henrietta Street, W.C.—H.S. (male).

SALFORD ROYAL HOSPITAL.—(1) Two H.S. (2) C.H.S. Males. (3) Hon. Assistant S.

SALVATION ARMY MOTHERS' HOSPITAL, Clapton, E.—J.R.M.O. (female).

SAMARITAN FREE HOSPITAL FOR WOMEN, Marylebone Road, N.W.—H.S.

SCARBOROUGH HOSPITAL AND DISPENSARY.—H.S. (female).

SHEFFIELD: CHILDREN'S HOSPITAL.—(1) H.S. (2) H.P. Males, unmarried.

SHEFFIELD: JESSOP HOSPITAL FOR WOMEN.—R.M.O. at Firth Auxiliary.

SHEFFIELD RADICAL CENTRE.—J.M.O.

SHREWSBURY: ROYAL SALOP INFIRMARY.—R.H.P. (male).

STOKE-ON-TRENT: NORTH STAFFORDSHIRE ROYAL INFIRMARY.—Assistant H.P.

SWANLEY: ALEXANDRA HOSPITAL FOR CHILDREN WITH HIP DISEASE.—R.A.M.O. (unmarried).

WATFORD AND DISTRICT PEACE MEMORIAL HOSPITAL.—H.S. (female).

WEST BROMWICH AND DISTRICT GENERAL HOSPITAL.—(1) H.S. (2) H.P. (3) C.O.

WEST LONDON HOSPITAL, Hammersmith, W.—(1) H.P. (2) H.S. (3) H.S. for Throat, Nose, and Ear Department. Males.

WINSLEY SANATORIUM, near Bath.—Whole-time A.R.M.O. (male).

WORTHING HOSPITAL.—H.S.

WREXHAM AND EAST DENBIGHSHIRE WAR MEMORIAL HOSPITAL.—Two R.H.S.

CERTIFYING FACTORY SURGEON.—The appointment at Holt (Norfolk) is vacant. Applications to the Chief Inspector of Factories, Home Office, Whitehall, S.W.1, by September 11th.

This list is compiled from our advertisement columns, where full particulars are given. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning. Further unclassified vacancies will be found in the advertising pages.

APPOINTMENTS

SCHOLEFIELD, B. G., M.D., M.Ch., F.R.C.S., Medical Referee under the Workmen's Compensation Act, 1925, for the Great Malvern, Hay, Hereford, Ledbury, and Leominster County Court Districts (Circuit No. 22).

STEWART, Matthew J., M.B., F.R.C.P., F.R.F.P.S., Honorary Pathologist, Leeds Public Dispensary and Hospital.

CERTIFYING FACTORY SURGEONS—T. B. Newman, L.R.C.P.I. and L.M., L.R.C.S.I. and L.M., for the Mullion District (Cornwall); J. C. C. Poole, M.B., B.Ch., for the Crowborough District (Sussex).

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements of Births, Marriages, and Deaths is 5s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

BIRTH

JOHNSON.—On August 19th, at Lorna Lodge Nursing Home, to Annie T. Leigh, M.B., Ch.B., M.R.C.S., L.R.C.P., wife of J. R. Johnson of School Road, Sale, Cheshire, a daughter. (See Deaths.)

DEATH

JOHNSON.—On August 24th, at a nursing home, Annie T. Leigh, M.B., Ch.B., M.R.C.S., L.R.C.P., the beloved wife of J. R. Johnson.

[The present issue being the Annual Educational Number, much current material is held over, and neither the "Supplement" nor the "Epitome of Current Medical Literature" is published this week.]

The British Medical Association:

ITS AIMS, WORK, AND CONSTITUTION

The British Medical Association, as stated in our introductory article on the Profession of Medicine, was founded in 1832 to promote the medical and allied sciences, to maintain the honour and interests of the profession, and to foster a feeling of friendship among its members. To attain these objects it holds meetings, local and central, for the discussion of medical and scientific subjects and of professional affairs; it publishes the *British Medical Journal*; it maintains a reference and lending library; it has instituted lectures, and scholarships and grants in aid of research. It concerns itself with every side of medical work—science, clinical medicine, public health, and the material interests of professional life. In addition to its work for them collectively and sectionally, the Association helps its members individually as to professional problems or difficulties, and the rendering of such help to its individual members forms a not inconsiderable part of the Association's daily work. The Association is the oldest, largest, and most powerful British organization devoted to the welfare of the medical profession. Its membership is now 34,750. It has a fine building in Tavistock Square, London, for its headquarters.

These premises, designed by Sir Edwin Lutyens, R.A., were formally opened in 1925 by His Majesty the King, Patron of the Association; and the beautiful wrought-iron gates erected as a memorial to the 574 members who fell in the war, by which the main quadrangle is completed, were dedicated on that occasion by the Archbishop of Canterbury. The need for larger accommodation had become insistent owing to the remarkable growth in the central work of the Association during recent years, which had far outstripped the capacity of the premises in the Strand.

British Medical Association House: Court of Honour

Constitution and Administration

The Association has Branches and Divisions throughout Great Britain and Ireland, and also in the Dominions, Colonies, and Dependencies. Thus, there are 47 Branches and 205 Divisions in the British Isles, and 86 Branches and 51 Divisions in the British Empire over-seas. The Branches in Australia and South Africa are linked up in Federal Councils for these respective areas. To the Association there is affiliated the Canadian Medical Association. Members of Divisions elect representatives on the Branch Councils and also a member or members of the Representative Body, which is the governing body of the Association and determines its policy.

The Council is the executive of the Association. It is elected partly by the Divisions and Branches and partly by the Representative Body, and includes representatives of the Navy, Air Force, Army, and Indian Medical Services elected by the Representative Body. The Representative Body and Council elect standing committees to take charge of different subjects. Among these may be mentioned the Science, Medico-Political, Ethical, Hospitals, Public Health, and Naval and Military Committees. There are Committees also for the Dominions, Scotland, Ireland, and Wales; and for the working machinery of the Association, such as the Organization, Finance, and Journal Committees. The Insurance Acts Committee, elected partly by the Association

and partly by insurance medical practitioners, is financed by the Association; it is the recognized executive and mouthpiece of the insurance practitioners of Great Britain and Northern Ireland.

Privileges of Members

- A member of the Association has the right—
1. To attend the annual and other general meetings of the Association and the meetings of the Division and Branch to which he or she belongs.
 2. To take part by personal vote (or in some Divisions by voting paper) in the election of the representative of his or her Division in the Representative Body, and also in the election of members of the Council.
 3. To receive by post the *British Medical Journal*, published weekly, which gives a full record, with commentary, of progress in clinical and scientific medicine, and of medico-political affairs and medical economics.
 4. To receive the help and advice of the central office in any professional difficulty.
 5. To use the Library as a reading room, and to borrow current medical or scientific books on payment of postage.
- Besides modern works and periodical medical literature—foreign as well as English—the library contains many books of historic interest.

The full benefits of the Association can only be secured by the co-operation of large numbers of the medical profession, for the greater the membership and the funds the more efficient and influential the organization. The Association has been the direct means of benefiting every class of medical men and medical women. In seeking new members it looks not only to the older practitioners but also and especially to those recently qualified. To these a generous concession is made as regards subscription, and there is a special appointment in the public services or in civil life. The Association's work for the Services is well known. It feels a special responsibility towards those members of the profession who by reason of their position are precluded from taking common action.

Subscriptions and Applications for Membership

The ordinary subscription to the British Medical Association is 3 guineas a year for members resident in the British Isles, but this is subject to various exceptions. Thus, newly qualified practitioners elected within two years of registration pay half this sum up to the end of the fourth year after registration; medical officers on the active list of the R.N., R.A.F., R.A.M.C. (Regular), and I.M.S. pay 2 guineas; concessions are made also to members (in the British Isles) of forty years' standing, to members of ten years' standing who have retired from practice, to married couples residing together, and to certain whole-time teachers and research workers. The ordinary subscription for members living abroad is 1½ guineas, but some Branches have special local subscriptions. A member elected after June 30th pays half the subscription for that year.

All duly qualified British medical practitioners are eligible for election. Full particulars can be obtained from the Medical Secretary, B.M.A. House, Tavistock Square, London, W.C.1; the Scottish Medical Secretary, 7, Drumsheugh Gardens, Edinburgh; or the Irish Medical Secretary, 18, Kildare Street, Dublin.

BRITISH MEDICAL JOURNAL

LONDON: SATURDAY, SEPTEMBER 8th, 1934

B. COLI INFECTIONS: AETIOLOGY AND TREATMENT*

BY

D. M. LYON, M.D., D.Sc., F.R.C.P. (Ed.).

PHYSICIAN TO THE ROYAL INFIRMARY, EDINBURGH; PROFESSOR OF THERAPEUTICS AND CLINICAL MEDICINE IN THE UNIVERSITY OF EDINBURGH

The colon bacillus in the healthy individual is a harmless saprophyte, which possibly assists in the later stages of digestion. Under certain conditions it seems to be the organism responsible for infections in almost any part of the body. Inflammatory lesions in or adjacent to the alimentary canal are often due to this organism, and apart from these the sites most frequently affected are the urinary tract and the gall-bladder. In all cases the original source of the infection is doubtless the bowel, and much inquiry has been directed to the methods of spread to the secondary sites. The organism grows most freely in the caecum and ascending colon, where the contents of the bowel are still fluid, but the drier conditions in the lower colon are less favourable to it, and many die off. Some bacilli also exist in the lower ileum, though never in great numbers unless stasis be present. The neighbourhood of the duodenum is usually sterile. It was long believed that the healthy intestinal mucosa offered an effective barrier to the passage of organisms from the bowel. This does not seem to be strictly true, for several workers have confirmed the observation of Adami¹ that organisms may penetrate the wall of the bowel without causing any lesion during their passage. Doubtless lymphatic glands and liver serve as additional lines of defence. Warren and Whipple,² by x-ray application, destroyed the epithelium over large areas of the small intestine, and found that no massive invasion took place, though some organisms reached the neighbouring glands. Recent opinion suggests that a few organisms are constantly leaving the bowel, to be rendered harmless in the body.³

Infection of the Urinary Tract

There has been much controversy concerning the path by which colon bacilli may reach the urinary tract, but neither clinical nor experimental evidence is sufficient to give a conclusive answer. It is possible that under suitable conditions the organisms may pass by any of the paths suggested. Spread may occur by natural passages, by lymphatics, by the blood stream, or by a combination of these. At several points the alimentary canal and the renal system lie in close contact, separated only by a little connective tissue, and direct penetration may take place. In such situations lymphatic plexuses may offer a more ready path. There may also be invasion of the portal veins or of the general circulation by way of the thoracic duct. Ascending infection in the urinary tract is believed to occur along the lymphatics which surround the ureter. In females there may be direct spread across the perineum to the lower urethra, but upward extension along the lumen is usually considered

unlikely, even when gross obstruction exists.⁴ That urinary infection occurs more frequently in female infants at the diaper stage has been held to favour passage spread, but Nabarro⁵ has drawn attention to certain fallacies, and in any case the lesion appears most commonly in the right kidney before the bladder is involved. Most writers now seem to prefer the theory of blood spread to the kidney. If this be so, organisms circulating in the blood stream should reach other parts of the body, and should affect both kidneys equally, yet the right is involved much more frequently than the left. This theory also fails to explain why women are more liable to pyelitis than men.

Much experimental work has been done in trying to elucidate the problem. The feeding of large quantities of foreign *B. coli* to dogs resulted in the appearance of some organisms in distant tissues, and in the urine in three cases out of four.⁶ Direct injections into the blood stream have given information of rather negative value. The healthy circulation appears to possess an enormous protective capacity, for even when billions of organisms are introduced into a vein urinary infection may fail entirely,⁷ and the blood may be sterile within an hour.⁸ In similar experiments Book found that bacteria did not appear in the urine for many hours, and then only if local foci had been developed in the kidneys.⁹

Peritoneal injection of large quantities of *B. coli* culture result in a rapid appearance of the organisms in the blood stream,¹⁰ and some can be recovered from the urine within half an hour.¹¹ Thiele and Embleton¹² describe some interesting observations. They painted organisms in the anterior urethra of guinea-pigs, and found that they were rapidly conveyed by lymphatics to the capsule of the kidney and then by lymphatic paths to the general circulation. None were carried directly to the bladder. Reinfection of the body appears to occur readily from the urinary tract. Barrington and Wright¹³ investigated the blood before and after minor operations on the urethra. In a large percentage of cases slight trauma to the mucosa was followed by the arrival of organisms in the blood within a few minutes. The bacilli disappeared within half an hour.

Many observers have shown that the colon bacillus does not readily establish itself in the blood stream or in the urine in healthy animals. It would seem that factors other than the mere presence of the organisms are necessary for a lasting implantation.

Age and Sex Incidence

B. coli infections of the urinary tract may develop at any level from a urethritis to pyelonephritis and perinephric abscess. Pyelitis is probably the commonest

* Read in opening a discussion in the Section of Medicine at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

lesion, while others are so mild as to suggest a bacilluria. Some writers consider these terms unjustified, and believe that there is always some underlying invasion of the kidney substance^{12, 26}; it should be remembered, of course, that only the more severe cases are examined by the pathologist. Urinary infections occur at any age, and are more frequent in females, both infants and adults. In males they are seldom found unless some obstruction is already present. When lesions affect different levels of the urinary tract the kidney is usually involved earlier than the bladder. Debilitating conditions, the presence of other disease, exposure to cold, fatigue, overexertion, starvation, undernutrition, and addiction to alcohol and drugs will undoubtedly favour infection by lowering resistance. These may affect either the bowel or the urinary tract.

Many practitioners have considered constipation and intestinal stasis important factors, but proof is difficult because of the frequent occurrence of these. Colitis, ulceration, diarrhoea, and the abuse of purgatives are equally important. Walker⁴ has proposed that a dose of cascara should be given to test whether a case of bacilluria has been completely cured. Such a dose will result in a reappearance of organisms in the urine if health has not been restored. No claim has been put forward that foreign bacteria in the bowel are more likely to gain entrance to the body. In the urinary tract the most important factor seems to be the presence of some obstructive lesion which interferes with free drainage. Experimentally this is also true, though the lesion may be very slight; obstruction of the urethra for as short a time as fifteen minutes may enable an infection to occur.¹³ In men enlarged prostate, stricture, and calculus favour infection, also nerve lesions such as tabes. Enforced rest after an operation, and unduly long retention of urine from any cause, are also said to be of importance. Mechanical causes, such as prolapse and external pressure, act in the same way. Pyelitis is common about the middle of pregnancy, and this may depend on the dilatation of the right renal pelvis, which is almost constant in this condition.⁴ The presence of foci in the gall-bladder or appendix may keep up a bacilluria.

Gall-bladder Infection

Infection of the gall-bladder may take place in much the same way as in the case of the urinary tract. Organisms may reach the liver by the systemic or the portal blood vessels, by lymphatics, and by the common bile duct. The bile, though alkaline, is an excellent culture medium for the colon bacillus and similar organisms. Typhoid bacilli are believed to reach the liver by the blood stream, and colon bacilli may arrive by the same path. Hurst¹⁴ has pointed out that where achlorhydria is present the contents of the duodenum are more alkaline—a condition favouring the growth of organisms—and retrograde infection of the biliary system is more likely in such cases. He also states that laparotomy, when followed by complete inhibition of gastric secretion and movement for a time, will allow *B. coli* to appear in the stomach within twenty-four hours.

In the gall-bladder the bacilli attack the walls, and so form a focus from which the bile can be constantly re-infected. As in the case of the urinary tract, the mere presence of organisms in the biliary system is probably not the only factor. Williams and McLachlan, studying the bacteriology of the gall-bladder, formed the impression that the *B. coli* and streptococci which were found were secondary invaders, enabled to settle down because of some toxic or chemical injury to the parts.¹⁵ The presence of gall-stones favours infection, and these depend to some extent on the occurrence of a high blood

cholesterol, though bacteria may also play a part in their formation. Anatomical abnormalities and mechanical faults leading to stasis or defective drainage of the gall-bladder are also of importance. Again, the presence of other foci of infection may predispose. Hurst reports that 37 per cent. of cases of cholecystitis had appendix scars.¹⁴

Septicaemia

Despite the apparent ease with which intestinal organisms invade the blood stream, true *B. coli* septicaemia is comparatively rare. Experiments already quoted have shown that even after massive infection the organisms fail to maintain themselves in the circulation. On the other hand, transient bacteraemia is probably very much more common than is usually supposed. Barrington and Wright have shown that organisms frequently reach the blood from the urethra if the urine is already infected⁴; Baird, who investigated the blood after labour, found coliform organisms within a few minutes of delivery, though they rapidly disappeared after an hour.¹⁶ He also draws attention to the danger of urinary infection in the puerperium from inability to pass water for some hours post partum.

As in the case of the local lesions, other factors appear to be essential for the development of septicaemia. It has been suggested that many cases of *B. coli* septicaemia may really be the overflow of bacteria from some local focus, such as the appendix or gall-bladder.

Treatment of *B. coli* Infections

A knowledge of the factors which permit an invasion of the body by the colon bacillus suggests measures which may be taken to prevent the infection: avoidance of debilitating and exhausting conditions, and the correction of all lesions which interfere with free drainage in the urinary and biliary systems. As the bowel is undoubtedly the original source of all infections, special attention should be directed to its proper functioning. Constipation must be corrected, but, in dealing with this, drastic purgatives must be avoided, as these carry fluid contents and more active organisms to the lower colon, and it has been shown that this may cause an exacerbation of the distant infection.⁴ Diarrhoea must be controlled, and other lesions of the bowel should be attended to.

The importance of such conditions is beyond doubt, but there may be other less obvious factors which favour invasion of the body. Colon bacilli isolated from distant lesions are usually of the same types as are commonly present in the alimentary canal, and it has not been held that foreign strains are more prone to cause infections. The importance of increased numbers of active *B. coli* in the small intestine or in the distal colon is more difficult to assess. In health the proportion of the various groups of organisms in the faeces is practically constant,¹⁷ but in certain conditions the stools may show an unusual preponderance of one or other type. Recognition of such abnormalities would warrant an attempt to correct them.

The so-called intestinal antiseptics are probably of little assistance, for in doses which are safe they cannot possibly sterilize the gut, and little is known of their effect on the various kinds of bacteria. Calomel in non-purgative doses is probably as useful a drug as any, and sulphur may also be of service. Many practitioners rely on preparations of liquid paraffin and agar for keeping the bowel in order. High colon lavage may be employed to get the lower bowel into a healthy state. An attempt may be made to alter the intestinal flora by implanting *B. acidophilus* and by giving lactose. Whole-wheat bread, uncooked starches—such as oatmeal—and sour meal preparations have been proposed for the same purpose.^{2, 18} There

is a certain amount of evidence that excess fat in the diet favours penetration of the bowel wall by organisms⁷; butter and eggs are therefore usually restricted. Almost all writers agree that milk should be avoided during the acute stages of renal infections, and meat is usually also restricted.

Measures to Raise Resistance

In dealing with *B. coli* infections bacteriological measures have not proved as satisfactory as might have been expected. This is probably due to the fact that the term "colon bacillus" does not represent one organism (as *B. typhosus* does), but includes some scores of different though closely related germs. Vaccine therapy has proved of service in the case of other infections, especially where the condition has become chronic, and benefit might be anticipated in the case of *B. coli* lesions. Opinions on this matter are very varied, and the usual belief appears to be that vaccines are seldom helpful. In view of this uncertainty it might be well to rely on autogenous preparations whenever possible.

Introduction of the bacteriophage has suggested interesting therapeutic possibilities. The interaction of phage and bacteria is so specific that it is unlikely that stock preparations can be of universal service. Few writers have claimed success in *B. coli* infections, and most have expressed doubt as to whether the method is worth the trouble it involves. Cowie¹⁹ gives a good account of the elaborate steps which are necessary to develop a satisfactory phage for each individual patient, but the results he reports seem to justify the special technique.

The bacteria of the colon group are said to produce two toxins—an endo- and an exo-toxin. Antisera have been produced against *B. coli* which are claimed to be both antitoxic and antibacterial.^{20,21} Even polyvalent sera can only be made against a few strains of organisms, and this probably explains why inconstant and unsatisfactory results are obtained.

Treatment of Urinary Infections

Some infections of the urinary tract are extremely mild and clear up spontaneously, others with tissue invasion and destruction may defy all attempts at cure. The majority lie between these extremes. For the acute phase treatment is standardized, but the chronic stages require individual measures. In acute cases the patient must be put to bed and kept uniformly warm. Large quantities of fluid should be given, together with alkalis, and perhaps an antispasmodic, such as hyoscyamus. Milk, meat extracts, and soups should be avoided; barley water, fruit juices, and glucose drinks should make up the fluid intake to three or four pints a day. Many writers suggest that copious flushing of the urinary tract is by far the best remedy for these infections.

By Administration of Alkalis

Alkalis are also very helpful in the early stages, and it has been stated that if alkali treatment were more efficiently carried out there would be fewer chronic cases.^{22,23} The colon bacillus can grow in media ranging from pH 4.4 to 9.4, and flourishes best between pH 6 and 7, a little to the acid side of neutral. Relief of symptoms may be obtained with relatively small doses of alkali which scarcely affect the pH, and even very large amounts of alkali can hardly raise the pH above 8,²⁴ at which value the organisms can still grow. The beneficial action has not been satisfactorily explained, since the change in pH hardly seems sufficient. The alkalis most commonly employed are potassium citrate and sodium bicarbonate up to 150 or even 300 grains of each in the twenty-four hours. One or more doses may also

be given during the night. These salts should be continued for several days after the temperature becomes normal, but they are apt to cause depression if kept up too long. It is often useful to have each specimen of urine tested with litmus paper to make certain that sufficient alkali is being given. In children, after the subsidence of symptoms, the urine should be kept mildly alkaline for weeks, and in pregnancy the alkalis should be continued to the end of term.

By Acidifying the Urine

When satisfactory administration of alkalis has not been successful in relieving the condition, the effect of acidifying the urine should be tried. Alternate periods of seven to ten days on alkali, and then on acid, may prove more successful than the continued use of either. The production of an acid urine is a necessary preliminary to the use of hexamine. Dilute acids are seldom used for this purpose, but acid sodium phosphate is usually employed. This salt will readily change alkaline urine, but it does not have much effect on a urine already acid. Ammonium benzoate is probably better, but it also fails to carry the acidity beyond the normal range. The acidifying chlorides of ammonium and of calcium act in a different way, and can produce a lower pH. They are apt to cause nausea and general upset, and a highly acid urine tends to irritate the urinary tract.

The Action of Hexamine

In trying to modify the reaction of the urine the character of the diet is of the greatest importance, for if the foods yield an alkaline ash extra acid will be required to overcome it. A large series of internal antiseptics have been prepared for sterilizing the urinary tract, but none is perfect. Disinfection of a healthy canal is comparatively easy, but organisms which have penetrated the walls of passages are beyond their action. Another difficulty is to attain a sufficient concentration of the drug in the urine. Of the urinary antiseptics hexamine is probably that most generally used. It acts by liberating formaldehyde, a change which takes place only in an acid medium. A solution of 1 in 5,000 is bactericidal, but such a concentration is probably never attained in the urine. It is doubtful whether 1 in 20,000 is often exceeded, and at such a concentration the growth of *B. coli* would only be inhibited. In addition, some of the drug is probably decomposed in the gastric juice, especially if it is given after meals. Acid-forming salts must be given at a sufficient interval from the hexamine, so that interaction will only occur in the urine. The combination of antiseptic and acid urine may be very irritating in the urinary tract, and this treatment must be avoided in acute infections, since haematuria or even strangury may be produced. In an alkaline urine the hexamine is excreted unchanged. It is interesting to note that certain writers believe that here, as in the alkaline bile, hexamine can benefit the patient in some other way than by producing formaldehyde. Some *B. coli* infections clear readily with hexamine and an acid urine, but lesions in the kidney and renal pelvis are less easily controlled, as little formaldehyde may be evolved at this level. Failure with hexamine is undoubtedly due to the difficulty in obtaining a sufficient concentration of the antiseptic.

Hexyl-resorcinol is said to be germicidal in either acid or in alkaline urine. It has a remarkable effect in rapidly clearing up coccal infections of the lower urinary tract, but in other respects it is not better than other antiseptics.²⁵ *B. coli* infections may require months of treatment where other organisms disappear in a short time. The fluid intake should be restricted during the

use of this drug, to increase its concentration in the urine.

Dyes of the pyridine series have recently been employed as urinary antiseptics. They also can be used without regard to the reaction of the urine, and it is claimed that they can penetrate the walls of the tract and so exert an antiseptic action in the tissues. The flavine series have been used by mouth, intravenously, and for local irrigations. They have the advantage that their action is not impaired by the presence of serum. Euflavine is probably the best of the group, the urine being made alkaline with sodium bicarbonate. In chronic cases a succession of such remedies can be tried. Attention must be directed to possible foci of reinfection, and any factor which may cause stasis or retention must be dealt with. In certain cases, as in pregnancy, the indwelling ureteral catheter is of temporary advantage.

The Ketogenic Diet

The observation that the urine of diabetics with acidosis and of epileptics under the ketogenic diet did not readily become infected suggested the use of this type of diet in cases of urinary infection. To produce the appearance of ketone bodies in the urine a very strict dietary control is essential. The diet contains large quantities of fat, and the carbohydrate has to be restricted to between 20 and 30 grams. After a few days on this strict regime acetone bodies begin to appear in the urine, and the pH may fall to about 5. Tested on a group of chronic cases which had resisted all other forms of treatment, this method proved successful in about one-half the patients, the infection clearing up in remarkable fashion in some of the cases.²³ The ketogenic diet is unappetising and even nauseating, and it is difficult to get patients to co-operate thoroughly for any length of time. It is unlikely that this method of treatment will be much used except in the most resistant cases.

Biliary Infections

The effects of treatment in lesions of the biliary tract can be less easily observed than in the case of the renal system. During the acute phase general measures must be taken against pain and fever. For chronic infections, where surgery is not indicated, other medical methods may be tried. As in the case of the urinary tract, an effort should be made to flush the system. A copious intake of fluid may be helpful in producing a free flow of bile. Drainage of the gall-bladder and biliary passages may be regularly undertaken by introducing concentrated magnesium sulphate through a tube in the duodenum. Specimens of the bile can be withdrawn and examined bacteriologically if care be taken to avoid contamination, but the results so obtained are not very reliable. Hurst¹⁴ finds that magnesium sulphate by mouth (without the tube) is just as efficient. He gives each morning the largest dose of a concentrated solution which the patient can take without being purged. The action may be further enhanced by an injection of pituitrin a quarter of an hour before taking the Epsom salts. Half an ounce of olive oil before meals may stimulate a flow in the same way. Treatment can be reinforced by the administration of sodium salicylate or hexamine; the salicylate is an efficient cholagogue. Hexamine reaches the bile, and is frequently prescribed in conditions of the gall-bladder, but as the medium is alkaline it is difficult to see how it can act. Hurst says that it can clear up an infection in a few days.

In *B. coli* septicaemia a search should be made for a focus of infection which may be constantly passing organisms into the circulation. Intravenous medications are of doubtful value. Mercurochrome has been most often given, but it is not without danger.

CONDITIONS PREDISPOSING TO B. COLI INFECTION AFTER POST-OPERATIVE RETENTION*

BY

CUTHBERT DUKES, M.Sc., M.D.

PATHOLOGIST, ST. PETER'S HOSPITAL; DIRECTOR OF RESEARCH
LABORATORY, ST. MARK'S HOSPITAL

The *B. coli* infections of the urinary tract which follow post-operative retention can be studied with a completeness which is not possible in sporadic infections. Tests can be carried out before the operation to find if the urinary organs are healthy, and periodic examinations during convalescence will show at what time and in what circumstances the urine becomes infected. The observer is in the fortunate position of knowing when the patient will be exposed to the risk of infection: he can look for common factors in those who succumb and those who escape.

During the last six years I have had the opportunity of making daily observations on 214 cases of retention of urine following the operation of excision of the rectum for cancer. This operation does not open or directly damage the urinary tract, but like other extensive pelvic operations it disturbs the nervous mechanism of micturition, necessitating catheterization usually for three or four days. In many of these cases urinary sepsis supervenes, the infection being attributable either to instrumentation or to a lymphatic or haematogenous infection from the operation wound. Other patients escape infection. We are discussing the aetiology of *B. coli* infections to-day, and my contribution consists in a demonstration of those conditions which predispose to infection when the function of the bladder is temporarily deranged after surgical operations.

Incidence of Infection

It will help towards an understanding of the question if before describing the factors which predispose to infection in this type of case I mention some which do not

* Read in opening a discussion in the Section of Medicine at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

affect the frequency of urinary infections. Changes in nursing personnel, for instance, made no difference to the proportion of urinary infections, and the incidence was approximately the same in each ward of the hospital. It was natural to look into this question because the women patients were all catheterized by sisters and senior nurses. Retention in men patients was relieved by an indwelling catheter with an antiseptic seal,¹ and the fact that only a small proportion of the men patients became infected is a tribute to the good quality of the nursing at St. Mark's Hospital. If less care had been taken with the sterilization and passage of catheters there would no doubt have been a higher proportion of infection. Similarly, it was found that the incidence of infection was approximately the same in the practice of each of the six surgeons on the staff of the hospital, and did not vary in the three operations commonly performed for cancer of the rectum—namely, perineal, abdomino-perineal, and perineo-abdominal excision.

It was also interesting to notice that minor defects in renal function, such as are accompanied by a rise in the blood urea to 50 or 60 mg. or a fall in the van Slyke urea clearance test to 40 or 50 per cent. did not predispose to urinary infection: there was no greater frequency of infection in the group showing these defects compared with other patients whose renal function tests before operation were more satisfactory. More severe defects in renal function would probably have predisposed to urinary infection, but such cases were not accepted as operable.

Causative Factors

Turning to the factors which influence the frequency of urinary infections, much the most obvious is sex. Infections following post-operative retention are much commoner in women than in men. In the whole series

FIG. 1.—Infection following post-operative retention of urine. Incidence in each sex.

of 214 patients, *B. coli* infection developed in ninety-nine (46 per cent.). Infection occurred in forty-seven out of sixty-eight women (69 per cent.), but in only fifty-two out of 146 men (36 per cent.) (see Fig. 1). This higher incidence of infection in women is not unexpected when one considers the difficulty of catheterization in a woman helpless after an extensive pelvic operation. In these circumstances the urine generally becomes infected within twenty-four hours of the commencement of catheterization, and pyuria supervenes two or three days later. In men patients, drained by a self-retaining catheter with an antiseptic seal, it is possible to keep the urine sterile and free from pus for several days. Thus, during the last few years nearly 100 men patients have had a catheter tied in for three to six days without any infection other than a slight urethritis.

Next to sex the most important factor predisposing to urinary infection is old age. The risk of infection increases steadily with advancing years both in women and in men. Of the women under 60 only 62 per cent. became infected after post-operative retention, but in those over

60, 86 per cent. developed *B. coli* infections. Similarly with the men—only 28 per cent. of those under 60 became infected, compared with 47 per cent. of those over this age (Fig. 2). This increased frequency of urinary infections in elderly subjects is attributable in women patients chiefly to loss of muscle tone, and in men to the increasing incidence of prostatic disease. Both these influences result in a longer period of retention, and as a general rule the longer the period of retention the greater the risk of infection.²

FIG. 2.—Influence of age in liability to infection in post-operative retention of urine.

The relation of the period of retention to likelihood of infection is shown by the fact that in men who suffered from retention for more than three days 38 per cent. became infected, but only 15 per cent. of infections occurred among those whose retention lasted a shorter

FIG. 3.—Influence of duration of retention of urine in liability to infection.

period. Similarly with the women—infections occurred in 76 per cent. of those requiring catheterization for more than three days, and in only 56 per cent. of those with retention lasting less than three days (Fig. 3).

Discussion

Finally, it is possible to show from this analysis that the patient's general state of health is an important factor in the incidence of urinary infection after post-operative retention. All the patients on whom these observations have been made had undergone the operation of excision of the rectum for cancer. In the early stages of this disease the general health is not impaired, but when the growth has ulcerated extensively and commenced to invade the extrarectal tissues there is a serious decline in the patient's general condition. Early cases are thus in a much better state of health at the time of operation than late cases. The lowered vitality is reflected in the increased incidence of generalized sepsis, and the higher operative mortality rate in the "C" group of cases, in which the glands contain metastases.³

The influence of the stage of the cancer on the risk of urinary infection is shown by the fact that among women 77 per cent. of the late cases became infected and only 59 per cent. of the early cases. Similarly, among men in only 32 per cent. of the early cases and 42 per cent. of the late cases the average age in each group was approximately the same, and it seems justifiable to attribute the increased incidence of urinary infection in the more advanced cases of cancer to a decline in general health.

Fig. 4.—Influence of the patient's general condition as shown by the frequency of post-operative urinary infections in early and late cases of cancer of the rectum.

These four factors—sex, age, duration of retention, and general health—are each responsible for considerable variation from the average in the incidence of *B. coli* infections after post-operative retention. The last three are to some extent dependent on each other, the duration of the retention being related to the age group and also to the patient's general state of health. Moreover, although for descriptive purposes these four factors have been considered separately, it must be pointed out, in conclusion, that they all predispose to infection because of their influence on the functional activity of the bladder. From the point of view of the subject under discussion their main interest lies in the fact that they exemplify a principle, familiar in urinary pathology but not always so easy to demonstrate in detail, that urinary infections are often dependent on defective function of the urinary organs.

The creation of new slum areas by smoke-polluted atmosphere is to receive special consideration at the annual conference of the National Smoke Abatement Society, which will be held at Glasgow from September 27th to 29th. Dr. J. Johnstone Jervis, medical officer of health for Leeds, will be the chief speaker on the subject of slum clearance and smoke prevention. Dr. J. S. Owens, who is in charge of the investigations into atmospheric pollution on behalf of the Department of Scientific and Industrial Research, and has invented many of the delicate instruments used for the measurement of atmospheric pollution, is to describe the latest development of smoke emission will also be demonstrated. Special delegates will be given a civic reception by the Lord Provost in the City Chambers, and the discussions will take place in the Council Hall. The chairmen at the various sessions will include Dr. H. A. Des Vœux, president of the society, and Dr. John R. Currie, professor of public health at Glasgow University.

THE VALUE OF RADIOLOGY (DIAGNOSIS AND TREATMENT) AS AN AID TO THE GENERAL PRACTITIONER*

J. H. DOUGLAS WEBSTER, M.D., F.R.C.P.ED.
PHYSICIAN IN CHARGE OF THE RADIOLOGY DEPARTMENT,
MIDDLESEX HOSPITAL

The three specialties—surgery, radiology, and pathology—have both a technical and a medical side, and have had eminent exponents of one or both aspects. Radiology occupies a position midway between the other two: it is in many ways ancillary, as pathology and bacteriology are (from the practitioner's point of view), while in other ways it is more independent, as the surgical specialties are. Again, the radiologist can rarely diagnose or treat "at a distance," as is the custom of the pathologist and the bacteriologist. The presence of the patient is usually as essential to him as it is to the surgeon. Radiology is therefore more a clinical specialty than a laboratory specialty.

Some of the more outstanding pioneers in the subject have been better known as biologists than as technicians. Some years ago Sir John Bland-Sutton, in speaking of members of his own craft, drew attention to this distinction, and few will deny that radiologists will be more likely to rise high in scientific reputation and in usefulness to their colleagues and the community when they regard themselves primarily as physicians—physicians who practise in radiology—than when they consider themselves only, or essentially, as technicians. In so far as they take their proper place as medical consultants rather than as technical consultants they will face far greater difficulties, and will have many opportunities, too, for exercising tact, both with patients and with their colleagues, but their value and general usefulness will in time be much greater.

Value of a Diagnostic or Therapeutic Method

The value of a diagnostic method is established by its affording evidence which can throw new light on obscure clinical problems, and still more when it can afford signs of such high value as evidence that they can be called pathognomonic. Radiology, it has been said with much truth, has brought forward a far greater number of such pathognomonic signs in its short existence than all the previous centuries of clinical observation could accumulate. In ancient medicine, and well on into the Middle Ages, physicians found, as they thought, infallible diagnostic and prognostic signs in astrological calculations or "images" (Chaucer): the position of the stars at the time of onset of the illness was generally agreed to be pathognomonic. Magic in diagnosis is less popular now, but in treatment, radium—to the public at large, and even to some members of the profession—has undoubtedly magical properties. The more scientific and less magical bases of diagnosis and prognosis began early in clinical observation, and later on progressed as the study of physical signs grew in accuracy. Thus in auscultation as a method we have relative and absolute examples of value in the discovery of a mitral systolic murmur, which can have one of many different interpretations, as compared with that of the presystolic murmur of mitral stenosis (crescendo, and heard supine). While some of radiological authorities, such as Köhler, regard the value of radiological diagnostic evidence as always relative and quite secondary to clinical findings, I rather agree with

* Read in opening a discussion in the Section of Radiology and Electrotherapeutics at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

those others, such as Holzknécht, who consider many roentgenological signs as pathognomonic, or more nearly absolute in value.

A long list of useful and pathognomonic signs could be given, but a few instances may suffice: a timely chest examination, which may reveal early tuberculosis masked as influenza, or military tuberculosis masked as enteric; bronchiectatic cavities made evident with lipiodol injection; horizontal fluid levels found in lung abscesses, or in gastro-intestinal diverticula, small bowel obstruction, or sinusitis; the demonstration of early aortic aneurysm, or of early heart enlargement; in the gastro-intestinal tract, the unequivocal signs of ulcer or growth, or of such conditions as diverticulitis and polyposis; again, in the examination of the gall-bladder, kidneys, nervous system, and bones and joints there are a great many signs which can well be called pathognomonic.

The value of a therapeutic method is established when it can relieve and possibly cure more "quickly, safely, and pleasantly" than any other method some or many groups of diseased conditions, and still more when it can show a specific curative action on malign processes which are otherwise intractable. In dermatology, gynaecology, and in almost all the other branches of medicine and surgery, the advances in radiotherapy have been immense; and in many fields, such as inflammatory infections, new discoveries are being made almost yearly—as, for instance, the possible value of treatment of pneumonia by short-wave diathermy, and the x-ray treatment of acute and subacute sinusitis and mastoiditis.

By all tests, diagnostic and therapeutic, radiology stands high. In diagnosis it has thrown a flood of light into most of the branches of medicine and surgery, and of its success in therapeutics the same may be said. Thus, apart from the knife or cautery (or to a much less degree foreign proteins and metals), x rays and radium are the only agents known to have an influence on malignant growth. This is the unique achievement of radiotherapy.

Good and Bad Radiology

The first criterion of the value of radiology must be that it is *good* radiology, as estimated by the higher current standards of excellence. Radiology is not nearly so established a science yet as pathology or surgery, with the result that there has been in the past, and still is, far too much imperfect radiology in all its branches—diagnostic and therapeutic x rays and radium therapy.

As an instance of diagnostic error we may recall the fact that hundreds of recruits for the armies of Great Britain and America were wrongly rejected because of the confident radiological diagnosis of "peribronchial phthisis." The boundaries of the normal and pathological in chest radiographs were not nearly so well established twenty years ago as they are to-day, and many radiologists in the war followed pseudo-scientific dogmas which some had laid down, based on false views of chest pathology. From time to time one still hears of extraordinary instances of wrong interpretations of radiographs. There was the recent case of an eminent foreign doctor who spent many months in bed owing to a wrong x-ray diagnosis of "spinal disease" which had been made by a surgeon. Again I may instance a patient who came home from a far-distant colony because of the wrong interpretation of his spasmodic "cascade stomach." He had returned expecting to have a gastric operation, but surgical intervention was shown to be quite unnecessary. Similar and more tragic instances of wrong x-ray and radium treatment are not infrequent, as are instances of failure to apply these agents where indicated.

Radiology: Major and Minor

The problems of correct interpretation in diagnostic radiology are so great, and the subject is still so far from fully explored, that Haenisch of Hamburg, for example, in a recent address in America on "Radiology as a Specialty," held that there is (and can be) no "minor roentgenology" corresponding to "minor surgery" or "minor pathology." I doubt, however, whether this position will meet with general agreement. Surely almost all fractures and dislocations, many foreign body localizations, and much of the fields of elementary thoracic and genito-urinary diagnosis can be held to be "minor roentgenology." If we admit no "minor" roentgenology how shall we prevent technical assistants, radiographers, or general practitioners from practising radiology to a greater or less degree? Granted that interpretation is a medical prerogative, it seems to me that technical and elementary diagnostic radiology cannot be restricted to medical specialists in the subject. In the spheres of electrotherapy and actinotherapy much may be said to be "minor," and can well be delegated to qualified biophysical assistants or technicians. On the other hand, in the sphere of radiotherapeutics (x-ray and radium therapy), little can be said to be "minor radiotherapy," except perhaps some of its dermatological applications.

Lay unqualified practice in radiology should be forbidden by law, just as the prescription and administration of poisons is legally restricted. An American doctor has reported recently a large number of cases of severe gum and jaw damage resulting from x-ray treatment for hypertrichosis administered in beauty parlours.

Radiology as a Specialty: Education

While a new medical science is emerging from the general body of medicine it first proves itself of value to medical and surgical specialists; only later on, when it becomes a consolidated science and art, does it make a wider appeal, reaching the general practitioner and the public. Radiological work is highly appreciated already by our specialist colleagues in medicine and surgery, for the statistics of all radiology departments show that year by year they refer a greater proportion of their hospital patients to us both for diagnosis and for treatment. Radiology has recently been accorded official recognition as a specialty by the institution, by some of the universities and colleges, of diplomas in this science and by insistence on a course of study in the subject by medical students—the general practitioners of the future. For graduate study with a view to specialism a three-years' course is required in some countries, as compared with our one year's special training. In some university hospitals abroad the students receive instruction during their earlier years in the anatomical, physiological, and pathological bases of both diagnostic and therapeutic radiology before the clinical applications are reached. This is an advisable, but at present only, I fear, an idealistic method.

Some raise objection to the overburdening of the undergraduates' curriculum by special teaching in radiology. Students are supposed by some to be able to acquire the knowledge they need in the subject in the wards and out-patient department, but this is impossible; they could gain little in the way of an adequate knowledge of pathology in this manner. Training in any subject must be reasonably full and precise. Take, for example, ophthalmology: here the medical student has to learn all the details of operations, such as those for squint, cataract, and the enucleation of the eye, but he is not likely to put his knowledge into effect by operating on

his patients once he commences private practice. No more is he likely to practise as a radiologist because of an elementary knowledge of the subject. If the curriculum is overburdened, much of what is unnecessary in it should be drastically excised so that sufficient attention can be paid to recent subjects of such great and general importance as radiology.

It is difficult for us to realize how the whole face of medicine and surgery has been changed within the lifetime of most of us by the advent of radiology. Thus the fourth edition (1902) of Osler's *Medicine* had only about 100 words on *x* rays in a monumental volume of nearly 700,000 words of text; and his 1912 edition was much behindhand in its references, failing to note the use of *x* rays in diagnosis of lung tuberculosis or gastric cancer, though it is mentioned as of help in "hour-glass stomach." But in 1907 there were already observations on pulmonary tuberculosis as shown by *x* rays; in 1908 on cancer of the stomach and colon; and in 1911 surgical and radiological advances.

Advance in any new specialty is slow enough owing to internal and external obstacles, but recognition by others of the advances made is even slower. We should realize that the diagnostic and curative possibilities of radiology will largely remain as, so to speak, capital locked up and not put to full use, unless its achievements can be so exhibited as to make a wide appeal to the general practitioners of each country. Many practitioners use it only as the medical defence societies urge—for fractures and dislocations. Others are over-credulous, as the practitioner in America who lately referred a patient to a radiologist for measurement of the mitral valve! Radiology offers an immense range of opportunities for proving its value, and has also very definite limitations: to diffuse more widely accurate knowledge of it the very active Radiological Society of North America has recently organized a three-year campaign of education in radiology throughout the country, and it might be well perhaps if its example were to be followed here. The private practitioners in a country have a unique position; they see the vast majority of patients first of all, and they are thus in a position to advise their patients (for example, in cases of gastric ulcer) whether they will undergo medical, surgical, or other specialist treatments. In addition, practitioners have a very good knowledge of the ultimate results of medical or specialist treatments. Their co-operation, therefore, must be solicited if the general level of health of the community is to benefit by recent advances in medicine.

As to delay in diagnosis, do we not often see patients who have suffered for years from undiagnosed gastric symptoms before a barium meal examination has been suggested? And in the sphere of treatment, how many patients suffering from exophthalmic goitre, leukaemia, and menorrhagia have spent months or years of ill-health with little-availing medical treatment before radiotherapy has been adopted?

Early Diagnosis and Treatment of Cancer

The most important sphere in which the co-operation of the general practitioner is essential is the early diagnosis and treatment of malignant disease. This has been insisted on by all the cancer organizations throughout the world, but it is only by the general practitioners gradually coming to realize the possibilities of radiotherapy that early treatment can be instituted for very many cancer patients. There are two reasons for this: (1) that so many patients are already at an inoperable stage by the time the disease is disclosed or discovered; and (2) that so many patients are not good operative

risks or have an invincible repugnance to operation. Because of this, the possibilities of radiotherapy should be widely known, and for each case should be explored without delay. Many of these patients would benefit by being referred directly to the radiotherapist. Professor Regaud has well said that the *first* treatment that the cancer patient has is the all-important treatment, and that it is quite indefensible to take up the attitude of only calling on the aid of the radiotherapist when surgery has proved a failure. On the contrary, the radiotherapy expert should be asked for his opinion before the commencement of each patient's treatment, in case radiotherapy is indicated then or at a later date.

If we consider the statistics of the Ministry of Health as to the number of deaths occurring annually from cancer of different regions—for example, 5,000 or more from cancer of the breast—we may ask: For how many of such cases has adequate radiotherapy been utilized? And where such a valuable aid has not been called in: What circumstances prevented its utilization? It is in the public interest that such questions be asked. I ventured to point this out in an article in the *Lancet* on breast cancer six years ago, but the question still awaits a satisfactory solution.

This discussion would, I believe, prove of permanent value if, under the auspices of the Section in the British Medical Association, or otherwise, steps could be taken towards an active campaign in radiology similar to that which has been carried out in Sweden at intervals in the past twenty years, and has been in progress lately in North America in the medical and lay press. Such campaigns have resulted in Sweden, and ought to result in Anglo-Saxon lands also, in a material raising of the general standard of the public health, and in an increased respect of the public for modern medicine, and for radiology, one of its most recent—and valuable—subdivision.

RADIOLOGY AS AN AID TO THE GENERAL PRACTITIONER*

E. KAYE LE FLEMING, M.A., M.D., B.Ch.

In this discussion I speak as a general practitioner who regards all kinds of specialist treatment as primarily arising from the needs of the general practitioner, and closely associated with, and dependent upon, his interest and co-operation.

In most forms of specialist practice the association between specialist and general practitioner is close, and necessitates consultation between the parties, to the advantage of all concerned. An exception to this relationship exists notably in the case of the bacteriologist and pathologist. Here the assistance required can generally be obtained without a personal interview. Nevertheless, even in this case, I am of opinion that there is a definite loss in the acquisition of knowledge by both parties resulting from the lack of personal discussion and the substitution of written reports.

The relationship between the radiologist and general practitioner may be said to fall somewhere between the ideal of the surgical or medical consultation and the more remote pathological or bacteriological report. My first point is to advocate a more close and personal contact between the radiologist and the general practitioner. I think that in the peculiar nature of your specialty there is a danger of the tie becoming weakened further

* Read in opening a discussion in the Section of Radiology and Electrotherapeutics at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

or even lost, to the disadvantage of all concerned. The reasons for this may be put under three heads.

1. The science of radiology (especially in its therapeutic aspect) is technically outside the sphere of knowledge of the general practitioner.

2. The science of its application is advancing so rapidly that the general practitioner in busy practice cannot hope to keep pace with it. In the case of those of my own standing in the profession it may be said to have developed altogether since we entered practice.

3. It is necessarily an *expensive* specialty. The general practitioner has to study closely the means of his patient, and must therefore often hesitate to recommend an expensive form of treatment without good knowledge of its nature and its probable efficacy.

With these general observations I turn to the main conditions which experience leads me to seek your assistance, and I have no doubt that if my knowledge of your specialty was more complete there would be fewer gaps in the rather disjointed category which I have made out.

The Field of Diagnosis

(a) *Bone Injuries and Misplacements.*—The value of x rays needs no emphasis in this class of case. While it is easy to point to the necessity of this kind of examination in all cases (the Medical Defence Union is eloquent on this point) in practice this is not possible. The general practitioner must discriminate to save needless expense. For example, as medical officer to a public school, if I acted literally on this advice I should be sending a daily stream over here to be examined by x rays. I could give more work to the radiologist if there were a simpler and less expensive method of examining minor injuries to show direct fracture or misplacement. I am quite aware of the difficulties involved, and am in no doubt as to the answer I shall receive.

(b) *The Thorax.*—I will not do more than acknowledge the great help of x rays in locating fluid in the pleural cavity. As regards pulmonary tuberculosis, the public has a blind faith in the result of an x-ray picture of the chest in the diagnosis of this condition. The interpretation of those films (in which I am specially interested) is, I think, one of the most difficult and highly specialized branches of x-ray reading. Their practical value is great in persuading a patient with early symptoms to appreciate the need for strict treatment. I think the practitioner without more than a general knowledge is apt to be unduly impressed by signs of disease. He would sometimes take a more reasoned view if he had a film of his own chest as a standard. The value of this form of examination in ascertaining whether disease is sufficiently unilateral, in deciding the suitability of limiting expansion by artificial pneumothorax or phrenic avulsion, is now well recognized.

As regards the heart, during war service at Netley I was fortunate in having opportunity during spare time of screening chests in the x-ray room. At first, chiefly interested in lungs, I soon became more and more interested in screening the heart shadow, and became accustomed to screen all patients with heart symptoms in my wards. The value of the information derived from this addition to the usual methods of examination impressed itself more and more forcibly on me. There is a saying that "Every picture tells a story," and I think this is true of the x-ray picture of the heart. The variation in shape and size, the vertical and transverse limits, the general appearances of the shadow can, I think, add appreciably to the knowledge necessary in treating heart conditions. On attempting to put this method into practical use on returning to civil practice I was confronted with a difficulty that I had not foreseen. It is only when the method used is the same that results are

comparable. I would press to-day the need for a fixed method of procedure in making these examinations. The upright position, the distance at which exposure is made, the clear definition of the mid-sternal line and the nipple point, when possible, are the most important points.

(c) *Abdomen.*—The bismuth meal raises a special problem. There is need for something more simple and less expensive than an elaborate and costly series of beautiful pictures where expense is so often an important consideration. In many cases a series of drawings from screening, with regional photographs, would be sufficient. The results of x-ray pictures of doubtful appendix cases is disappointing in my experience. How far can we rely on an x-ray of the gall-bladder or kidney in the case of suspected stone? Has the introduction of the use of dyes reached a degree of certainty in such cases?

Treatment

There are in my experience various conditions in which the general practitioner feels the need of this kind of treatment, but is often deterred by lack of knowledge of the likelihood of its success.

Exophthalmic Goitre.—I believe treatment by x rays of this group of diseases is carried out frequently. Personally, having seen one case where the result appeared to be most unsatisfactory, I have hesitated to advise it again. If there are cases which are suitable for this method of treatment, what are the conditions by which they can be distinguished?

Sterilization in the Female.—The general practitioner is keenly interested in the production of sterility in the female by x rays or radium. The most common type of case is where production of an artificial menopause or the quickening of the natural process is necessary for the welfare of the patient. I hope we shall hear to-day something definite on this point. The practitioner wants to be in a position to say to his patient that this form of treatment will entail (roughly speaking) so many visits to the radiologist and the approximate cost. I would emphasize at this point how much the practitioner needs to know the cost and time factors in all kinds of specialist treatments. A further important point in cases of this kind is how far we can assure or reassure our patients on the after-effects of such treatment.

Sterilization to Prevent Conception.—I am not one of those (and there are many in the profession) who view with alarm the state of the law in this country in this connexion. I have had cases, and I can envisage others, where I should not hesitate to advise and abet in obtaining security against conception by x rays or radium. It would be of interest to hear if radiologists view with disquiet the giving of treatment with this object on the request of a practitioner of experience and repute. One frequently hears in the ranks of both the profession and the public the opinion that the laws of this country need amending in relation to sterilization and the induction of abortion. I can only say in my professional experience I have never felt the need, nor have I felt handicapped in giving advice or treatment to this end.

Skin Treatment.—I imagine that practitioners as a class are fully alive to the success of radium and x ray treatment of malignant disease of the skin and epithelioma. Rodent ulcer, cancer of the lip and tongue, and of the cervix, are cases in point. But there are many conditions of the skin where the practitioner feels that x ray treatment might be of value, but he is ignorant of its possibilities. Many dermatologists must be using the form of treatment in the more chronic skin eruptions. Why do we not hear more of the results and the conclusions at which they arrive? How far can we rely on such treatment, for example, for a speedy cure of multiple warts on the hands? Patches of psoriasis and the like

TUBERCULIN TESTS IN INFANTS AND CHILDREN

[THE BRITISH
MEDICAL JOURNAL]

and Mantoux (1 in 1,000) tests appear equally sensitive, the Mantoux (1 in 100) more so, and no further positive reactions were obtained with the dilution 1 in 10. Roughly, the number of positive reactions per 100 children under 2 years with the Pirquet test and Mantoux test, in the three increasingly strong dilutions, are 4, 4, 6. In the older group comparison of the three tests is possible, as there were no reactions with the ether, and the number of positive tests is much greater. The number of positive reactions per 100 children, aged 2 to 16 years, for the three tests were therefore: Moro, 42 to 39 (see footnotes ⁴ and ⁵ in Table II); Pirquet, 48, and Mantoux (in the three increasingly strong dilutions), 50 (see footnote ⁶), 55 (see footnotes ⁸, ⁹, and ¹⁰), 61 to 55 (see footnotes ¹¹, ¹², and ¹³).

To summarize, it may be stated that the Moro test is the least sensitive of the three tuberculin tests, the Pirquet and the Mantoux (1 in 1,000) about equally sensitive (in favour of the latter), the Mantoux (1 in 100 and 1 in 10) increasingly more sensitive than the last two. It is interesting to note that while in children under 2 years the Mantoux (1 in 100) increases the number of positive reactions by 50 per cent. on the Pirquet, it is only two more children in a 100 that are found positive. In the older group the number of positive reactions is increased by 13 per cent. only, but six to seven more children per 100 tested are found positive. Thus in testing infants the chances of finding a positive reaction with the Mantoux test when the Pirquet is negative are very much smaller.

Finally, it should be noted that all the diagnosed or suspected cases of clinical tuberculosis were found to be Pirquet-positive and Mantoux-positive (1 in 1,000), but that two of these patients were negative to the Moro test: (a) pulmonary tuberculosis (T.B. found), and (b) tracheo-bronchial adenitis (no T.B. found).

(B) TECHNICAL ADVANTAGES AND DISADVANTAGES IN PRACTICE

The Pirquet test is undoubtedly the simplest to perform: the material is always at hand, the vaccinostyle looks like a nib and does not frighten the child, and the test can be carried out most rapidly. Certain precautions must, however, be taken. Thus: (1) so far as possible bleeding

should be avoided, as this may prevent contact of the tuberculin with the dermis; (2) the control scarification should be made above and not below the tuberculin, as otherwise the latter may run down on to the control area; (3) the lower scarification should be done *through* the tuberculin and the tuberculin should be left exposed to the air for at least a few minutes, after which it may be gently wiped off (a dressing should not be applied, as the latter magnifies the importance of the operation in the eyes of the parents); (5) it is suggested that whenever possible the test be carried out by the medical man himself.

The reputed claim of the simplicity of the Moro test cannot be maintained. Thus: (1) if Table I is referred to it will be seen that out of the twenty-six positive tests in nine the area rubbed with tuberculin only gave no reaction, and in thirteen more the reaction was less marked in the area which had previously not been rubbed with ether, the preliminary cleansing of the skin with ether thus appearing to be essential; (2) the rubbing of the skin with ether gives rise in the young children (for whom the simplification of a tuberculin test is particularly desirable) to false reactions (see Table I), presumably due to their more tender skin: hence, it is essential that a control area rubbed with ether only should form part of the test; (3) the older children in this investigation strongly objected to the smell of the ether, the rubbing with ether proving, in fact, to be the most trying part of all the procedures, and, presumably, is very disagreeable to infants who cannot voice their protests; (4) rubbing two areas with ether and then one with ointment renders the operation a more prolonged one than either the Pirquet or the Mantoux test; (5) the test is messier than either of the other two, as the grease does not dry; (6) a positive reaction often results in a group of papules covering an area as much as 7 cm. in diameter, and this is more objectionable to the parents than the single erythematous patch of a positive Pirquet or even Mantoux test; and (7) it is advisable to have the ointment freshly prepared.

The Mantoux test has the following disadvantages. (1) The dilutions must be fairly freshly prepared (not more than two weeks old); (2) the test is more of an operation in the eyes of children and parents, as something is injected and the apparatus is more complicated; (3) it is more painful. Even if the needle is small and sharp, pain is

TABLE II.—Relative Sensitivity of the Three Tuberculin Reactions.

Age	Pirquet			Moro			Mantoux								
	No. Tested		Positive	No. Tested		Positive	1 in 1,000			1 in 100			1 in 10		
							No. Tested		% Positive of Whole Series	No. Tested		% Positive of Whole Series	No. Tested		% Positive of Whole Series
	No.	%		No.	%		No.	%		No.	%		No.	%	
Under 2 years	104 ¹	4	3.8												
	66 ²	3	4.5	66	2 ³	3.0	104	4	3.8						
2 to 16 years	62	30	48.3	60	24	40.0	61	30	49.1	52.0 ⁴	49.2 ⁷	3.8	95	2	2.1
										22	2	9.0			
										3 ⁸	19.0 ⁸	54.8 ⁹	53.2 ¹⁰	19	4-11 ¹¹
														21.0-5.2 ¹²	61.1-54.8 ¹³

¹ In one child the test gave a linear erythema; this was not considered positive, as the Mantoux test up to a dilution of 1 in 10 remained negative.

² Excluding thirty-eight cases in which the Moro test was not performed.

³ One of these reactions was very feeble (see Table I).

⁴ Assuming that the two patients not tested (one was in a plaster jacket and the other had a rash on the chest) would both have reacted positively.

⁵ Assuming that these two patients would both have reacted negatively.

⁶ Assuming that the patient not tested (supply of tuberculin ran out) would have reacted positively; almost certainly so as the Pirquet reaction was positive.

⁷ Assuming that this patient would have reacted negatively.

⁸ Adjusted on the assumption that the nine patients not tested (left hospital) would have reacted in the same proportion as those who did.

⁹ Dependent on ⁴ and ⁷.

¹⁰ In only one of these was the test definitely positive by the criteria adopted; in the others it was doubtful; thus the reactions were: (a) 15 by 22 mm ill-defined erythema (control negative); patient not seen on fourth day; (b) 12 by 15 mm ill-defined erythema (control negative), negative on fourth day; (c) 6 by 6 mm. faint erythema and slight swelling (control negative), patient not seen on fourth day.

¹¹ Assuming all four reactions with 1 in 10 dilution and the one not tested with 1 in 1,000 were positive.

¹² Assuming only one of the four reactions with 1 in 10 was positive and the one not tested with 1 in 1,000 was negative.

TABLE III.—*Mantoux Test. Doubtful and Minimal Reactions.*

Age	1 in 1,000								1 in 100								1 in 10							
	No. Tested		No. Positive		Minimal Reactions		Doubtful Reactions		No. Tested		No. Positive		Minimal Reactions		Doubtful Reactions		No. Tested		No. Positive		Minimal Reactions		Doubtful Reactions

* One of these became positive with dilution 1 in 100; another showed a slight stain only till the fourth day, when it developed a faint erythema 10 mm. in diameter; the other three with dilution 1 in 100.

† One of these became positive with dilution of 1 in 10.

‡ See footnote to Table II.

Numbers in parentheses represent reactions visible or showing stigmata at least on fourth day after performance of test.

caused by the distension during the injection (in infants considerable force is often required to eject even 0.1 c.c.m. from the ordinary hypodermic syringe) (4) if the test is negative with 1 in 1,000 dilution the parents are more likely to object to the repetition of an apparently exactly similar operation.

The test is considerably simplified, however, by the use of a Pictet intradermic syringe (see above).

(C) MINIMAL POSITIVE REACTIONS

Papuet Test.—A reaction should be regarded as positive if there is at least 1 mm. of erythema on each side of the lower scarification, in the absence of such change in the upper one. A linear erythema should not be regarded as positive, and it is advisable in such cases to carry out the Mantoux test (1 in 100). It should be noted that six of the thirty-four positive Papuet tests were more marked on the fourth day after the test.

Moro Test.—The presence of even one definite large papule on the area rubbed with the ointment, in the absence of any change on the area rubbed with ether only and of papules or a rash on the neighbouring skin, may be regarded as a positive reaction. However, owing to the frequency of the latter on many chests, it is advisable, when only one or two papules are present, or any doubt is felt, to perform a confirmatory test with the Pirquet or the Mantoux (1 in 1,000). An area of erythema only should not be regarded as a positive reaction.

Mantoux Test.—An area of erythema 10 mm. in diameter, showing some swelling to touch, or a well-defined erythema of greater diameter, should be regarded as the minimum required for a positive reaction. Erythematous 5 mm. in diameter up to the above measurement should be regarded as doubtful reactions, and the test performed with the next stronger dilution. Table III gives the number of these doubtful reactions with each dilution in each group. Only two out of a total of thirteen (1 in 1,000 and 1 in 100 dilutions only) were positive with the next stronger dilution. One of the positive reactions with 1 in 1,000 and one of the positives with 1 in 100 were doubtful two days after the test, but became positive on the fourth day.* It is therefore advisable, when a doubtful reaction is obtained, to postpone carrying out the test with the next stronger solution until the test has been reinspected on the fourth day.

Table IV gives the number of obviously traumatic reactions as shown by blue, green, or yellow colouring of bruising. It is of interest to note that the percentage is the same for both groups of children and whether an ordinary hypodermic or Pictet syringe is used.

* It should also be noted that five of the thirty-four positive reactions with 1 in 1,000, one of the four positives with 1 in 100, and the definitely positive reaction with 1 in 10 were more marked on the fourth day after the test.

Table III gives the number of minimal reactions noted—that is, all reactions showing erythema, or erythema and swelling, less than 5 mm. in diameter. It will be noted that their percentage increases with each dilution, particularly in the younger group. It must be emphasized that 118 out of 145 (80 per cent.) of even these reactions show some staining at least on the fourth day after test. The need for the use of a control test (as described) when the Mantoux test with the dilution 1 in 10 is employed is obvious, especially if the test is stopped at this dilution. The 145 control injections gave rise to eight reactions showing bruising, sixty-three (43 per cent.) minimal reactions, eight reactions corresponding to those described as "doubtful" (seven still visible on the fourth day), and four reactions (two visible on the fourth day).

TABLE IV.—*Mantoux Test. Reactions Indicating Bruising.*

Age	1 in 1,000			1 in 100			1 in 10		
	No. Tested	No. Showing Bruising	%	No. Tested	No. Showing Bruising	%	No. Tested	No. Showing Bruising	%
Under 2 years	124	8	7	55	10	18	87	6	7
2 to 16 years	61	3	5	22	3	14	19	3	16

All Dilutions

Age	No. of Tests	No. Showing Bruising	%	Group I Only	No. of Tests	No. Showing Bruising	%
Under 2 years	255	24	9	Ordinary syringe	107	9	8
2 to 16 years	102	9	9	Pictet syringe	173	15	9

measuring 10 mm. in diameter or more. Eleven of these last twelve reactions occurred in the children under 2 years. As, from what has already been stated, these minimal and doubtful reactions cannot be attributed to the trauma of the injection or to the type of syringe used, one is tempted to suggest that they are due to the irritation of some substance* in the broth in which the tuberculin is prepared, and that the infant's skin is particularly sensitive to it.

(D) THE B.C.G. VACCINATED CHILDREN*

While admitting that the smallness of the numbers renders conclusions impossible, it is nevertheless of interest

* This is left intentionally vague. Further work on this question is now being carried out by one of us (G. G. K.).

† The results under this heading appear contradictory with those obtained by one of us in papers previously published. Account should therefore be taken of the small number of vaccinated children here tested.—B. W.-H.

TUBERCULIN TESTS IN INFANTS AND CHILDREN

[THE BRITISH
MEDICAL JOURNAL]

and Mantoux (1 in 1,000) tests appear equally sensitive, the Mantoux (1 in 100) more so, and no further positive reactions were obtained with the dilution 1 in 10. Roughly, the number of positive reactions per 100 children under 2 years with the Pirquet test and Mantoux test, in the three increasingly strong dilutions, are 4, 4, 6, 6. In the older group comparison of the three tests is possible, as there were no reactions with the Mantoux (in the three increasingly strong dilutions), 42 to 39 (see footnotes ¹ and ² in Table II); Pirquet, 48, 50 (see footnote ³), 55 (see footnotes ⁴, ⁵, and ⁶), 61 to 55 (see footnotes ⁷, ⁸, and ⁹).

To summarize, it may be stated that the Moro test is the least sensitive of the three tuberculin tests, the Pirquet and the Mantoux (1 in 1,000) about equally sensitive (in favour of the latter), the Mantoux (1 in 100) and 1 in 10 increasingly more sensitive than the last two. It is interesting to note that while in children under 2 years the Mantoux (1 in 100) increases the number of positive reactions by 50 per cent. on the Pirquet, it is only two more children in a 100 that are found positive. In the older group the number of positive reactions is increased by 13 per cent. only, but six to seven more children per 100 tested are found positive. Thus in testing infants the chances of finding a positive reaction with the Mantoux test when the Pirquet is negative are very much smaller.

Finally, it should be noted that all the diagnosed or suspected cases of clinical tuberculosis were found to be Pirquet-positive and Mantoux-positive (1 in 1,000), but that two of these patients were negative to the Moro test: (a) pulmonary tuberculosis (T.B. found), and (b) tracheo-bronchial adenitis (no T.B. found).

(B) TECHNICAL ADVANTAGES AND DISADVANTAGES IN PRACTICE

The Pirquet test is undoubtedly the simplest to perform: the material is always at hand, the vaccinostyle looks like a nib and does not frighten the child, and the test can be carried out most rapidly. Certain precautions must, however, be taken. Thus: (1) so far as possible bleeding

should be avoided, as this may prevent contact of the tuberculin with the dermis; (2) the control scarification should be made above and not below the tuberculin, as otherwise the latter may run down on to the control area; (3) the lower scarification should be done *through* the tuberculin and the tuberculin not be deposited on it afterwards; (4) the tuberculin should be left exposed to the air for at least a few minutes, after which it may be gently wiped off (a dressing should not be applied, as the latter magnifies the importance of the operation in the eyes of the parents); (5) it is suggested that whenever possible the test be carried out by the medical man himself.

The reputed claim of the simplicity of the Moro test cannot be maintained. Thus: (1) if Table I is referred to in nine the area rubbed with tuberculin only gave no reaction, and in thirteen more the reaction was less marked in the area which had previously not been rubbed with ether, the preliminary cleansing of the skin with ether thus appearing to be essential; (2) the rubbing of the skin with ether gives rise in the young children (for whom the simplification of a tuberculin test is particularly desirable) to false reactions (see Table I), presumably due to their more tender skin; hence, it is essential that a control area rubbed with ether only should form part of the test; (3) the older children in this investigation strongly objected to the smell of the ether, the rubbing with ether proving, in fact, to be the most trying part of all the procedures, and, presumably, is very disagreeable to infants who cannot voice their protests; (4) rubbing two areas with ether and then one with ointment renders the operation a more prolonged one than either the Pirquet or the Mantoux test; (5) the test is messier than either of the other two, as the grease does not dry; (6) a positive reaction often results in a group of papules covering an area as much as 7 cm. in diameter, and this is more objectionable to the parents than the single erythematous patch of a positive Pirquet or even Mantoux test; and (7) it is advisable to have the ointment freshly prepared.

The Mantoux test has the following disadvantages. (1) The dilutions must be fairly freshly prepared (not more than two weeks old); (2) the test is more of an operation in the eyes of children and parents, as something is injected and the apparatus is more complicated; (3) it is more painful. Even if the needle is small and sharp, pain is

TABLE II.—Relative Sensitivity of the Three Tuberculin Reactions.

Age	Pirquet			Moro			Mantoux

¹ In one child the test gave a linear erythema; this was not considered positive, as the Mantoux test up to a dilution of 1 in 10 remained negative.

² Excluding thirty-eight cases in which the Moro test was not performed.

³ One of these reactions was very feeble (see Table I).

⁴ Assuming that the two patients not tested (one was in a plaster jacket and the other had a rash on the chest) would both have reacted positively.

⁵ Assuming that these two patients would both have reacted negatively.

⁶ Assuming that the patient not tested (supply of tuberculin ran out) would have reacted positively; almost certainly so as the Pirquet reaction was positive.

⁷ Assuming that this patient would have reacted negatively.

⁸ Adjusted on the assumption that the nine patients not tested (left hospital) would have reacted in the same proportion as those who did.

⁹ Dependent on ⁸ and ⁷.

¹⁰ In only one of these was the test definitely positive by the criteria adopted; in the others it was doubtful; thus the reactions were: (a) 15 by 22 mm. ill-defined erythema (control negative), patient not seen on fourth day; (b) 12 by 15 mm. ill-defined erythema (control negative), patient not seen on fourth day; (c) 6 by 6 mm. faint erythema and slight swelling (control negative), patient not seen on fourth day.

¹¹ Assuming all four reactions with 1 in 10 dilution and the one not tested with 1 in 1,000 were positive.

¹² Assuming only one of the four reactions with 1 in 10 was positive and the one not tested with 1 in 1,000 was negative.

TABLE III.—Mantoux Test. Doubtful and Minimal Reactions.

Age	1 in 1,000						1 in 100						1 in 10

¹ One of these became positive with dilution 1 in 100; another showed a slight stain only till eighth day, when there developed a faint erythema 10 mm. in diameter (negative with dilution 1 in 100).

² One of these became positive with dilution of 1 in 10.

³ See footnote ¹ in Table II.

Numbers in parentheses represent reactions visible or showing staining at least on fourth day after performance of test.

caused by the distension during the injection (in infants considerable force is often required to eject even 0.1 c.cm. from the ordinary hypodermic syringe); (4) if the test is negative with 1 in 1,000 dilution the parents are more likely to object to the repetition of an apparently exactly similar operation.

The test is considerably simplified, however, by the use of a Pictet intradermic syringe (see above).

(C) MINIMUM POSITIVE REACTIONS

Pirquet Test.—A reaction should be regarded as positive if there is at least 1 mm. of erythema on each side of the lower scarification, in the absence of such change in the upper one. A linear erythema should not be regarded as positive, and it is advisable in such cases to carry out the Mantoux test (1 in 100). It should be noted that six of the thirty-four positive Pirquet tests were more marked on the fourth day after the test.

Moro Test.—The presence of even one definite large papule on the area rubbed with the ointment, in the absence of any change on the area rubbed with ether only and of papules or a rash on the neighbouring skin, may be regarded as a positive reaction. However, owing to the frequency of the latter on many chests, it is advisable, when only one or two papules are present, or any doubt is felt, to perform a confirmatory test with the Pirquet or the Mantoux (1 in 1,000). An area of erythema only should not be regarded as a positive reaction.

Mantoux Test.—An area of erythema 10 mm. in diameter, showing some swelling to touch, or a well-defined erythema of greater diameter, should be regarded as the minimum required for a positive reaction. Erythematous 5 mm. in diameter up to the above measurement should be regarded as doubtful reactions, and the test performed with the next stronger dilution. Table III gives the number of these doubtful reactions with each dilution in each group. Only two out of a total of thirteen (1 in 1,000 and 1 in 100 dilutions only) were positive with the next stronger dilution. One of the positive reactions with 1 in 1,000 and one of the positives with 1 in 100 were doubtful two days after the test, but became positive on the fourth day.* It is therefore advisable, when a doubtful reaction is obtained, to postpone carrying out the test with the next stronger solution until the test has been re-inspected on the fourth day.

Table IV gives the number of obviously traumatic reactions as shown by blue, green, or yellow colouring of bruising. It is of interest to note that the percentage is the same for both groups of children and whether an ordinary hypodermic or Pictet syringe is used.

* It should also be noted that five of the thirty-four positive reactions with 1 in 1,000, one of the four positives with 1 in 100, and the definitely positive reaction with 1 in 10 were more marked on the fourth day after the test.

Table III gives the number of minimal reactions noted—that is, all reactions showing erythema, or erythema and swelling, less than 5 mm. in diameter. It will be noted that their percentage increases with each dilution, particularly in the younger group. It must be emphasized that 118 out of 145 (80 per cent.) of even these reactions show some staining at least on the fourth day after test. The need for the use of a control test (as described) when the Mantoux test with the dilution 1 in 10 is employed is obvious, especially if the test is stopped at this dilution. The 145 control injections gave rise to eight reactions showing bruising, sixty-three (43 per cent.) minimal reactions, eight reactions corresponding to those described as "doubtful" (seven still visible on the fourth day), and four reactions (two visible on the fourth day).

TABLE IV.—Mantoux Test. Reactions Indicating Bruising.

Age	1 in 1,000			1 in 100			1 in 10		
	No. Tested	No. Showing Bruising	%	No. Tested	No. Showing Bruising	%	No. Tested	No. Showing Bruising	%
Under 2 years	104	8	7.6	95	10	10.5	87	6	6.9
2 to 15 years	61	3	4.9	22	3	13.6	19	3	15.7

All Dilutions

Age	No. of Tests	No. Showing Bruising	%	Group I Only	No. of Tests	No. Showing Bruising	%
Under 2 years	236	24	10.2	Ordinary syringe	107	9	8.4
2 to 15 years	102	9	8.8	Pictet syringe	179	15	8.3

measuring 10 mm. in diameter or more. Eleven of these last twelve reactions occurred in the children under 2 years. As, from what has already been stated, these minimal and doubtful reactions cannot be attributed to the trauma of the injection or to the type of syringe used, one is tempted to suggest that they are due to the irritation of some substance* in the broth in which the tuberculin is prepared, and that the infant's skin is particularly sensitive to it.

(D) THE B.C.G. VACCINATED CHILDREN†

While admitting that the smallness of the numbers renders conclusions impossible, it is nevertheless of interest

* This is left intentionally vague. Further work on this question is now being carried out by one of us (G. G. K.).

† The results under this heading appear contradictory with those obtained by one of us in papers previously published. Account should therefore be taken of the small number of vaccinated children here tested.—B. W. H.

to point out that of the twenty-two infants who had been vaccinated with B.C.G. over six weeks before (sixteen over three months before)—all by mouth except two, four a second time since birth—only two were positive to a tuberculin test. Thus:

(a) Vaccinated subcutaneously nine weeks before test. Had been in contact with sputum-positive mother for a few days before admission. Negative Pirquet; positive to Mantoux (1 in 100).

(b) Vaccinated at birth by mouth seventeen months before test. Had been in contact for eleven months with a father who coughs, but whose examinations were stated to be negative as regards tuberculosis. Positive Pirquet and Mantoux (1 in 1,000).

Conclusions

In spite of the relatively small number of children here investigated we feel justified in drawing the following conclusions:

1. The Moro test is the least sensitive of the three tuberculin tests commonly employed. The Pirquet (pure tuberculin) and the Mantoux test (1 in 1,000) are about equally sensitive, the Mantoux (1 in 100) being definitely more sensitive.

2. For use in infants and young children the Moro test* has definite disadvantages as regards technique and interpretation of results. When employed, a control test with ether only should always be carried out.

3. The Pirquet test is, for infants and young children, the simplest and easiest test to perform, and should therefore be employed first. If found to be negative, an intradermal test with a dilution of 1 in 100 should then be carried out. In older children it is worth while to repeat the test, if still negative, with a dilution of 1 in 10.

4. The Mantoux test in a dilution of 1 in 10 should always be carried out with a control injection of the broth used for the preparation of tuberculin.

5. A Pirquet test should be regarded as positive only if there is at least 1 mm. of erythema on each side of the scarified area.

6. The minimum required for a positive Mantoux test with any dilution is an area of erythema 10 mm. in diameter, associated with some swelling to touch, or a well-defined erythema greater in area than this. Reactions showing an erythema 5 mm. in diameter or more should be regarded as doubtful, reinspected on the fourth day, and, if still doubtful or negative, the test should be repeated with a stronger dilution. If a reaction obtained with a dilution of 1 in 10 is on the fourth day definitely more marked than the control test, but still under the limit of a positive reaction as indicated above, it is advisable to regard the test as doubtful, and repeat it either within ten days or in three months' time.¹

7. It is suggested that instead of maintaining the controversy as to the relative value of the Pirquet and Mantoux tests, the test indicated here (Pirquet followed by Mantoux 1 in 100), combining both, should be adopted as a routine under a different name—for example, "the combined tuberculin test," or "the cutaneous intradermal test."

We should like to express our thanks to Professor Ombredanne for allowing us to test the patients under his care, to Dr. Guérin, of the Pasteur Institute, for supplying the broth used for the control test, and to the ward sisters for their help during the course of the investigation.

REFERENCE

* Hart, P. D'A.: Medical Research Council Special Report No. 164, 1932.

* The tuberculin ointment now prepared by Löwenstein and sold in small tin tubes as "dermotublin" contains only 40 per cent. tuberculin and is recommended to be used on the arm, back, chest, abdomen, or front of leg, after preliminary cleansing with benzene, ether, alcohol, or soap and water.

CHLOROFORM-HYOSCINE AMNESIA IN LABOUR

BY

JAMES CLARK, M.B., CH.B.ED.

In the *British Medical Journal* of May 26th, 1934, there is an admirable article on hyoscine amnesia in labour by Mr. Trevor Barnett. It stresses the value of hyoscine alone in producing an amnesia which is preferable to hyoscine-morphine narcosis. Mr. Barnett has verified that the use of hyoscine without the initial injection of morphine eliminates the oligopnoea of the newborn infant. In his conclusions he stresses three conditions which make it impossible for the general practitioner to employ the method he advocates. These are:

1. The need for constant supervision during labour.
2. Occasional necessity for two nurses to control the patient.
3. That the method cannot be employed unless one is assured of the presence of the possibly necessary skilled attendants. (These, perhaps, meaning a qualified medical assistant and two nurses.)

This valuable method, then, can only be utilized in a nursing home where such skilled staff is provided.

It is my intention to try to show that a modification of the hyoscine method has proved to be of great value as a domiciliary measure. During the last ten years in general practice I have conducted eighty-four confinements on the lines about to be described. The usual antenatal examination and care are observed, and the cases selected are those which one, as a general practitioner, would select for home treatment.

Details of Procedure

Treatment is commenced when the patient complains of pains which are regular and of moderate strength. The strength and duration of pains are best gauged by abdominal palpation. I have not found that any arbitrary division between first and second stages of labour assists one's judgement. The nervous constitution of the patient and the consequent degree of fear and sensitiveness to pain are more important. As the practitioner's efforts are directed towards saving the patient from any avoidable suffering, it is better to institute the treatment too early rather than let the pains assume too severe a character. Erring on the early side does not seem to protract the labour. After all, one is dealing with a psychosomatic process and not with a stereotyped mechanism which must conform to an average standard set by textbooks.

The patient is put to bed. One nurse is in attendance. An initial light anaesthesia is induced by chloroform until the patient is quiet and sleeping between pains. (It is the experience of most general practitioners that women in labour take chloroform very well.) A hypodermic injection of hyoscine (1/100 grain) is given immediately the patient is lightly under. The hyoscine is repeated in doses of half this amount at intervals varying from half an hour to an hour. The ideal to be aimed at is that the patient should be definitely drowsy and quiet between pains. During pains discomfort is evidenced merely by subdued groans and slight restlessness. Any indication of returning awareness can be controlled by immediate inhalations of chloroform and a subsequent injection of hyoscine. This use of chloroform as an intermediary often makes all the difference between a perfect amnesia and one in which a severe pain is recalled with extraordinary intensity.

One also finds that chloroform controls any restlessness which hyoscine may produce. This, however, is rarely

necessary, as the initial administration of chloroform seems to have a subduing effect throughout. The quiet nature of a confinement conducted in this manner is such that the assistance of only one nurse is ample. After experience of the method, one learns to judge for how long during labour the patient may be left in sole charge of the nurse. She receives instructions within the discretion of the medical attendant as to the times of the next one or two injections of hyoscine. As labour progresses the dose of hyoscine is diminished to 1/300 or 1/400 grain, and the intervals of injection lengthened or shortened according to the judgement of the practitioner. I always avoid giving any hyoscine during the hour immediately preceding delivery, and administer light chloroform from the time that the anus assumes the D shape until the head is born. Should labour be delayed, as it may be in any confinement, pituitrin may be used as in ordinary cases, with certain efficiency. Ordinary everyday stimuli should not affect the patient. By these are meant daylight or artificial light, sounds of outdoor traffic, sounds of quiet voices, and of walking in the room. There is no need, therefore, to darken the room, stuff the patient's ears with cotton-wool, or preserve in the house the silence appropriate to a death-chamber.

In no case does the amnesia seem to affect the condition of the infant at birth. The delivery of the placenta is often delayed, but not unduly so; in this one respect more patience is required than in the ordinary confinement.

Maternal loss and after-recovery remain unaffected. The mother sleeps or remains drowsy for some time. Anyway, the amnesia lasts beyond delivery for a period which is directly proportionate to the extent of the amnesia induced during labour. The mother usually emerges from her amnesia with a strongly expressed disbelief that her baby has arrived.

Advantages of Method

This method is particularly valuable in general practice for the following reasons:

1. Primiparae prefer to be confined at home; the first baby is an event, and the medical attendant is expected to get the patient out of her pain as soon as possible.
2. Multiparae who have previously had protracted or exhausting labours do reasonably demand that they should not "have to go through the same again."
3. It reduces the number of instrumental labours. The practitioner is relieved of the exhortations of the patient and her relatives to "get her out of her suffering soon."

It was in such a case that the writer developed the chloroform-hyoscine technique. A young primipara was sufficiently advanced in labour as to justify vaginal examination. This she subconsciously resisted. All that could be ascertained was that the head might be on the perineum. The patient and her relatives demanded early relief. Chloroform was administered with a view to applying Milne-Murray forceps. Under light anaesthesia it was found that though the os was paper thin, the head was not entirely on the perineum. Hyoscine (1/200 grain) was given immediately and two injections each of 1/400 grain at half-hourly intervals. (Morphine was avoided on account of the advanced stage of labour.) A further administration of chloroform was given on the first appearance of the head, which was born under control two hours after the first light chloroform was given. Three hours after delivery the patient was asleep, the amnesia having continued until she was in a natural sleep of fatigue.

4. It enables the general practitioner to enhance his reputation or to establish it. Here is something that clinics do not do, something that general nursing-homes might, but as a rule do not, countenance; yet something that still maintains the status of a medical man as the family doctor.

Clinical Memoranda

CARCINOMA VENTRICULI IN A WOMAN OF 90

In view of the extreme age of the patient and the scarcity of recorded cases of stomach cancers in old people, I think the following case worthy of record.

Mrs. A., aged 90, was admitted to the City Hospital, Plymouth, on May 30th, 1934, complaining that for the previous ten days she had had constant retching and vomiting, and had been "unable to keep anything down." The bowels had not been open for the last three days, but there was no history of previous ill-health. On admission the patient was obviously practically moribund and very wasted and cachectic, and there was also cyanosis of the lips and slight oedema of the ankles.

Abdominal examination revealed a hard, freely movable mass, with well-defined margins, situated in the mid-line just below the umbilicus. The mass was about 2 inches by 3/4 inch, and was dull to percussion. Examination of the heart and pulse showed that well-marked auricular fibrillation was present. A probable diagnosis of carcinoma of the transverse colon was made, but the patient was too ill for operation to be contemplated, and she died on June 1st.

At the necropsy it was found that the mass was due to a hard, sclerosing growth of an annular type involving the pyloric end of the stomach; the edges of the growth were extremely ill defined: there was no visible ulceration of the gastric mucosa, and a few hard glands were seen lying in the lesser omentum close to the growth. No visceral deposits were present apart from the primary growth. Microscopical section of the mass demonstrated the growth to be a typical columnar-celled carcinoma. There was extreme gastric dilatation above the growth, proving that almost complete obstruction had occurred. The heart showed extreme fatty degeneration.

COMMENTARY

The literature concerning cancer in the aged is very scanty, and no case of cancer of the stomach in a patient of this age has, I believe, been reported in recent years. According to Osler the ages at which cancer of the stomach occurred in 150 cases at the Johns Hopkins Hospital were:

Age	Cases	Age	Cases
20-30	6	50-60	49
30-40	17	60-70	36
40-50	38	70-80	4

In the *American Journal of Cancer* (February, 1934, xx, 477) Shore reports that in Finsterer's series of resections of the stomach for carcinoma, one-third of the patients were between the ages of 60 and 83. Finsterer found age *per se* no contraindication to operation; in fact, while the immediate mortality in the group (60-83) was 9.5 per cent., compared with 6 per cent. in the younger patients, the percentage of five-year cures was 40 in the aged, compared with 22 in the under 60 class, showing that carcinoma of the stomach in the aged is a relatively benign condition.

It is well known that cancer of the stomach can advance to the inoperable stage without giving much evidence of its presence, and in this case, though a growth was found post mortem which must, by its size, have been present for several months, no symptoms were complained of until a few days before the patient's death from pyloric obstruction.

It is, of course, possible that carcinoma of the internal organs in the aged occurs more often than is supposed, and that the diagnosis is seldom made owing to the rarity with which post-mortems are performed in such patients, and the difficulty in getting histories from persons of advanced years.

My thanks are due to the medical superintendent of the City Hospital, Mr. G. E. Larks, F.R.C.S., for permission to record this case, and to Mr. T. J. Shields, Librarian of the S.M.A. Library, for his kindness in searching the literature.

HENRY J. KNIGHT, M.B., B.S.
Resident Medical Officer, City
Hospital, Plymouth.

A CASE OF BR. ABORTUS FEVER

The following case may be interesting to those whose work lies in association with the acute infectious diseases and to tuberculosis officers to whom cases of asymptomatic pyrexia are often referred.

Miss X, aged 35, was a school teacher, living and working in a rural area; she had always been healthy. In January, 1934, she had a bad head cold and began to feel easily tired. In February she had "influenza," with a temperature. A stiff sore neck, lasting a week-end, occurred in March, 1934;

she felt seedy, and her work was an effort to her. By lunch-time she wished it were bedtime. This post-meridian fatigue became so marked that she decided to go on holiday to North Berwick. There, during Easter, she developed a head cold, and first noted that she had a persistent temperature. Soon troublesome profuse and diffuse sweating also began to trouble her, evening and during the night. A tentative diagnosis of tuberculosis having been made, the patient was seen by me in the capacity of tuberculosis officer on April 27th, 1934. Her only complaint was her "temperature" and the drenching sweats.

Slight constipation was present, but the appetite was fairly good. The patient looked alert. The skin was velvety and clammy, and there was no loss of subcutaneous fat. Pulse rate 96, soft, compressible, and of full volume. There was no acrocyanosis. Tongue dry and somewhat furred on the dorsum, clean at the tip and edges. There were no abnormal physical signs in heart, lungs, or abdomen, and taking into consideration the fact that, despite the high temperatures, there were no evidences of toxæmia, a diagnosis of miliary tuberculosis

was thought unlikely. A provisional diagnosis of *Br. abortus* fever was made on the findings of high temperature, post-meridian fatigue, and profuse sweating, combined with the absence of localizing signs and toxæmia. On May 1st an agglutination test was performed. This gave a positive agglutination with *Br. abortus* of Bang to a titre of 1 in 5,000.

The appended day temperature charts (compiled by relatives, and therefore lacking in technical precision) show the interesting comparison between temperature, fatigue, and sweating.

S. HARVEY, M.B., Ch.B., D.P.H.

AUTOTRANSFUSION IN GRAVE EMERGENCY

The following case seems to illustrate the value of autotransfusion in certain urgent circumstances. It is therefore placed on record.

R. S., a motor lorry driver, was admitted on August 2nd to the King Edward Avenue Hospital, Dartford, with a history of "a violent fall off his lorry on to the mudguard, severely injuring his left ribs." On examination the radial pulse was almost imperceptible at 150 beats per minute, temperature 96°F., and extreme pallor obvious. The patient was collapsed, but felt tenderness and pain on pressure over lower left ribs and left side of the abdomen. The abdomen was rigid, distended, and dull on percussion from the costal margin to the left flank almost to the mid-line—definite indication of a ruptured spleen with intraperitoneal hæmorrhage.

Using open ether as an anaesthetic, the spleen was isolated, the pedicle being ligatured, and, with the splenic vessels, removed. It was grossly lacerated, and ruptured completely through to the pedicle at the lower two-fifths, the peritoneal cavity being distended with blood. The escaping blood and the free blood in the peritoneal cavity were collected to the amount of 600 c.cm., strained through sterile muslin, citrated, and returned into the circulation through the median basilic vein. Only clots were removed from the peritoneal cavity, the residue of blood with serum being deliberately left in the peritoneal cavity along with normal saline. As the autotransfusion proceeded pulse and colour gradually improved, and the patient was returned to the ward in a very much better condition than when he left it. Continuous subcutaneous saline was administered (rectal was not possible), and 1/6 grain morphine given. Apart from three slight rigors without any rise of temperature thirty-six hours after operation, recovery was uninterrupted, and the patient, after ten days, felt perfectly fit. I ascribe the success of this case largely to the autotransfusion suggested and promptly carried out with exact technique by Dr. A. N. F. Critchley, house-surgeon.

COMMENT

This hospital has a satisfactory transfusion service, with donors available with reasonable promptness, but at its best this accessibility is not comparable with that of autotransfusion, as in this case. Further, such blood must be definitely superior for transfusion to blood from the best of donors (correct group or universal), none of which can be guaranteed to be 100 per cent. free from the risk of anaphylaxis in some degree. It would be interesting to know how far the field of autotransfusion has been explored and made use of. Excluding blood from infected parts, or blood containing extraneous material, such as the contents of ruptured liver cells or bile ducts, it would seem that where the patient's own germ-free blood could be carefully collected it would prove of great service for autotransfusion in cases with danger of fatal shock through hæmorrhage—for example, ectopics, ante-partum and post-partum hæmorrhages, and operation cases in grave injuries with hæmorrhage before and during operation.

M. W. RENTON,
Consulting Surgeon to King Edward's
Avenue Hospital, Dartford.

Reviews

MEDICAL BEHAVIOUR

An extremely wise book is *The Doctor and his Patients*,¹ a collection of papers by Dr. ALBERT KRECKE of Munich, translated from the second German edition by Margaret M. Green. There are twenty-three articles, all of them relatively short, and every one of them worth while. They deal with the relations of medical practitioners with one another and with their patients, most of them written from the point of view of an experienced surgeon for the benefit of the young general practitioner. They are full of understanding both of the mental attitude of patients towards their maladies and of the difficulties of the young doctor, whether family doctor or junior specialist, in the daily conduct of his work. There is naturally some repetition, and the book should not be read straight through, but there is not a chapter which may not be read and reread with profit. Most of the articles may, indeed, be described as almost models of what the inexperienced practitioner would wish to be told, and of the way in which a senior member of the profession may best pass on the results of the experience which he has gathered to those who stand in need of it. Every operating surgeon of many years' standing must be well aware of the doubts and difficulties arising from the circumstances of his practice and the decisions with the making of which he is confronted; but not every surgeon has so clear and constant an appreciation of the psychological reaction of the patient. Papers on "How Do Patients Picture the Nature of their Malady?" on "The Prevention of Pain," and on "The Fear of Cancer," illustrate the value of such an appreciation.

Chapters of a different character are indicated by the titles "Mania Operatoria," "Operations in Patients of an Advanced Age," "The Visual Examination of Patients," and "Washing the Hands." A still further variety of questions is dealt with in those headed "The Hospital Doctor and the General Practitioner," "Collusion between Doctors," "Something Went Wrong"; and yet another under such captions as "The Doctor's Woman Assistant," "How the Doctor should Read his Weekly Journal," "The Doctor When Ill," and "Payment by One Doctor to Another." These subjects do not exhaust the contents of the book, but they indicate the wide range of kindred matter with which it is concerned. The author modestly says: "If I discuss a question concerning the mental attitude of patients it is only a matter of several perfectly innocent observations which any doctor who does not regard his profession merely as a trade might make any day"; and again, "We are not taught these little things enough in our student days. We have to learn slowly in our practice the many means by which patients can be spared mental strain"; and "A man must have reached a certain age in order to perceive that surgery is not the universal remedy for which we are often apt to take it in our youthful enthusiasm." All sorts of wisdom for the guidance of daily practice, and for the cultivation of correct judgement in emergencies will be found within the covers of this book, and just now, when the ethics and etiquette of consultation are under consideration, it might be well for all concerned to read Dr. Krecke's paper on "Is it Justifiable to Advise and Treat other Doctors' Patients?"

It was judicious to place the short biography and appreciation of the author at the end of the book rather than at the beginning, for no one can read a group of

articles like these without a desire to know who was the skilled surgeon, the untiring worker, the sympathetic friend, the wise counsellor, who penned them. The conditions in which he worked and for which he wrote are German, and it is clear from several passages that the economic stress of the medical profession in Germany, and the effects of the insurance system, are less favourable than in this country, but the character of the problems, both scientific and ethical, with which a practitioner is confronted are almost startlingly similar in that country and here. The book is valuable and the translation well done.

SYPHILIS

A full account of Experimental Syphilis,² from the earlier days in the last century, when human beings were employed for the purpose, down to modern times, when animals of many kinds—chimpanzees, catarrhines, rabbits, guinea-pigs, rats, and mice—have been much employed, is given by GASTINEL and PULVENIS. The subject is discussed from many points of view, and there are chapters given to such matters as the ways in which the infection becomes generalized, the factors that may modify its results, the curious "asymptomatic syphilis" that may be seen in rabbits or mice, the occurrence and nature of immunity to syphilis in both human beings and experimental animals, and observations on Meinecke's reaction in experimentally infected rabbits. The book is well written, and contains a deal of information; it should be in the hands of laboratory workers.

Dr. RAVAUT's essay on a New Form of Syphilis of the Nervous System³ deals with the detection of syphilis by the changes it produces in the cerebro-spinal fluid in the days before there is any clinical evidence to show that the central nervous system has become infected; he describes it as a biological form of neurosyphilis, which can be detected only by examining the fluid yielded by lumbar puncture, and no doubt it is comparable to the asymptomatic experimental syphilis of Gastinel and Pulvenis mentioned above. The importance of the diagnosis and treatment of neurosyphilis at the earliest possible moment need not be stressed; Dr. Ravaut deals with the whole subject clearly and at length, in all its different aspects. The book should be read by all medical practitioners interested in the early diagnosis and treatment of syphilis of the nervous system.

A good general account of the methods nowadays employed in the treatment of neurosyphilis in the Vienna clinics is given by Dr. DATNER in his volume on the Modern Therapy of Neurosyphilis.⁴ Professor Wagner-Jauregg has furnished the preface, and as is naturally to be expected the treatment of general paralysis by infection with malaria or recurrent fever is given in detail. The importance of the examination of the cerebro-spinal fluid is emphasized, and full descriptions of the correct methods of performing lumbar puncture and of examining the fluid by many laboratory procedures are described, with admirable illustrative coloured plates. The results of treatment with various drugs are set out, and the difficulties of assessing the values of the treatments recommended are fully recognized. The book will be found of value by all who are directly interested in the diagnosis and treatment of syphilis of the central nervous system.

The illustrations and coloured plates are of a high order, though the drawings of the flies which concern themselves with meat are not up to the general standard. The work is intended for the information of meat consumers and for the guidance of those engaged in meat inspection. We think that it will serve both these objects in a thoroughly competent manner, and we recommend it to meat inspectors and medical officers in this country as a source of full and reliable information on the subject with which it deals.

PROTOPLASM AS A COLLOID

It has long been recognized that protoplasm behaves as a fluid, and that its solid constituents are not arranged in the form of anything like a fixed structure. It is a liquid, not a solid, and often a viscous liquid such as is classed by colloid chemists among the colloid solutions, or lyophilic colloids, of which examples are furnished by watery solutions of soaps, glues, and so forth. It has commonly been supposed that the massive and complex molecule of protoplasm, or biogen molecule, if such a thing may exist, is dissolved in the water that forms the major part of its substance ; or, if the idea of the biogen molecule seems too simple, one may say that protoplasm is a complex of substances of various chemical natures and in various states of aggregation, dissolved in water to form a sol while alive and liable to precipitation in the form of a gel when overtaken by death. In protoplasm and, indeed, in living tissues generally, it is the water that is commonly supposed to act as the solvent and to hold the solid constituents in colloid solution. The opposite view, however, is held by MARTIN FISCHER and MARIAN HOOKER,* who argue that protoplasm or, more generally, living matter, including the tissue juices like blood and lymph, is in essence a solution of water in a colloid matrix.

[THE BRITISH
MEDICAL JOURNAL]

Living cells, according to this view, are not droplets of dilute solutions in which colloid molecules (protein, fat, and carbohydrate) are suspended, but are described as lyophilic colloid systems, in which the water is dissolved in, and actually bound to, the colloid material. Protoplasm is briefly described as a base-protein-acid hydrated compound, an amphoteric electrolyte that is a solvent for water. Various applications of this revolutionary view of the constitution of living matter are made by Fischer and Hooker to such medical phenomena as oedema, acidosis, alkalosis, and the so-called permeability of living cells; they have abundant experimental methods and results to prove the correctness of their views, and argue that the physics and chemistry of dilute solutions, so long applied to the problems of living matter, should now be disregarded. They would concentrate attention on what, for lack of a better name, they call "solutions of inverse type"—solutions, that is, in which the dissolved substance is the water, the solid is the solvent.

LAW FOR THE ORDINARY CITIZEN

The plain man's ignorance of law is usually profound. This is unfortunate, for ignorance is no excuse for his breaking it. Moreover, it is no easy matter for him to ascertain the law on any given point. Legal textbooks are practically useless to him, and there are not very many good books which will explain the law to him in intelligent language. Some books of the type of *Everyman His Own Lawyer* are useful, but necessarily express themselves in general terms and attempt to cover too wide a range. *The Citizen and the Law*,¹ by "Solicitor," is without exception the best we have ever seen. One of its chief features is its vigorous detachment from the legal system, its humorous condemnation of the law's worst defects, and its wealth of illustrative anecdote. The author treats of such general subjects as litigation, the police, and dodging the law—which chiefly concerns income tax and bankruptcy—and deals at length with everyday puzzles in the field of household servants, motor-ing, and sport. He gives a very clear summary of the law of family relationships and of divorce. The chapter on doctors sets out shortly the law of qualification and the powers of the General Medical Council. "Solicitor" considers, rather surprisingly, that doctors charge too much. While he admits that many doctors charge too moderate fees or none at all to people without means, he suggests that some check ought to exist on doctors' bills similar to that by which solicitors' charges are taxed by officers of the Court. To his statement that to defend an action brought by a medical practitioner to recover his fees is generally useless, many doctors will be able to find a reply from bitter experience. One of the most serious and common bugbears of the doctor is the patient who brings a counter-action for negligence in order to avoid a perfectly reasonable account, and such actions owing to the usual sympathy of a jury with an ex-patient, not infrequently succeed. To appoint, as the author suggests, commissioners in every district to review doctors' bills would be an obvious and unjustifiable interference with private interests and the relationship between doctor and patient. It would be just as reasonable to have a similar tribunal to review the charges of every tradesman. Such tribunals have been set up in times of emergency, but there is no record that the results obtained were strikingly successful. Nevertheless, one can bear "Solicitor" no grudge for his opinions, which are sincerely held and add greatly to the interest of his book.

Notes on Books

PERKIN and KIPPING's *Organic Chemistry*. Part III,* incorporates those matters which are not usually presented in a fundamental course of instruction in the subject. Such matters naturally include the newer developments of theory, the results of recent important research, questions which still await a complete explanation, and descriptions of organic substances of more than ordinary complexity. These are discussed in this part. They include the theory of valency, which is based on the behaviour of electrons, the relation of physical properties to molecular constitution, and various forms of geometrical isomerism. There is also a more extended treatment of the subject of optical isomerism than that given in the foregoing section of the work, together with an account of the optically active forms of nitrogen, tin, silicon, and sulphur. A considerable part of the volume is occupied with the study of certain groups of interrelated substances, among which are found the saccharides, the terpenes, and the carotenoids, but the alkaloids are not here included. Room has, however, been found for a monograph on the more remarkable forms of tautomeric change occurring in organic substances. All these matters are discussed with special regard to the needs of students intending to take the honours degree. The book has been carefully prepared, and forms a fitting supplement to Parts I and II of the authors' work.

In their little book on *Sex in Marriage*† Mr. ERNEST R. GROVES, research professor of sociology in the University of California, and his wife, Mrs. GLADYS H. GROVES, have attempted to give sex information to those entering marriage, in the manner and the spirit of a book for beginners in housekeeping and child nurture. The subjects discussed include the elementary anatomy and physiology of the sexual organs, the love art of husband and wife, common problems of marriage, and birth control. A short bibliography of English works is appended.

The fifth volume of the German publication on the Results of General Tuberculosis Research¹⁰ contains much of interest for workers dealing with this disease. Three of the six contributions in the present collection deal with tuberculosis in childhood. Professor Stefan Engel has written a masterly review on "The Hilus of the Child," which closely correlates pathological and radiological findings. Professor Hans Opitz deals with the difficult question of whether children with intrathoracic tuberculosis can act as sources of infection, and concludes that there is more danger for other children than is generally realized. Dr. K. Mattison (of Sweden) discusses the fate of school children infected with tuberculosis, and covers a very wide field in the whole question of the age of infection and the resultant mortality and morbidity.

We have received a copy of the latest issue of the *Liverpool Medico-Chirurgical Journal*, vol. xlii, Part I.¹¹ This contains an interesting article on language, jargon, and modern medicine by Dr. Herbert R. Hurter. Two historical articles by Sir D'Arcy Power and Professor John Hay (the latter being the Commemoration Address on the Centenary of the School of Medicine) are followed by practical papers on midwifery analgesia and allergy by Drs. R. J. Minnitt and R. M. B. MacKenna, while Professor Walter J. Dilling offers a scholarly contribution on David Waldie, prophet of the anaesthetic properties of chloroform.

† *Sex in Marriage*. By Ernest R. Groves and Gladys H. Groves. With an introduction by Dr. Harry Roberts. London: Gerald Howe, Ltd. 1934. (Pp. 251. 6s. net.)

¹⁰ *Ergebnisse der gesamten Tuberkuloseforschung*. Band V. Leipzig: G. Thieme, 1933. (Pp. 427; 128 figures. M.43; geb. M.45)

¹¹ *The Liverpool Medico-Chirurgical Journal*. Edited by R. Coepe, M.D. Liverpool: Medical Institution; London: H. K. Lewis and Co., Ltd. 1934. (Pp. 132. 2s. 6d., published half-yearly)

Preparations and Appliances

RETRACTOR FOR EXTERNAL FRONTAL SINUS AND ETHMOIDAL OPERATIONS

Mr. GILBERT H. HOWELLS (London, W.1) writes: The instrument described and illustrated here has proved most satisfactory in use. The broad, curved blade slips in under the orbital periosteum and retracts the orbital contents without any danger of damaging the eyeball. The two small hooks on the opposite arm slip under the integuments, and, owing to their mobility on the arm, will adapt themselves to the curve of the incision. It is made by Messrs. Mayer and Phelps, Chiron House, 59, New Cavendish Street, London, W.1.

MODIFIED ETHER INHALER

Dr. F. R. GUSTERSON (Worthing) writes: Having found Mr. Denis Browne's ether inhaler very useful for anaesthesia in children, I have modified it in the following details, and use it as a routine for adults.

1. The face end has been made wider, and the sponge rubber facepiece dispensed with, a piece of gamgee being used.
2. Two gas tubes have been inserted so that oxygen and CO₂ can be administered if necessary.
3. A lid with revolving shutter has been fitted. This enables a certain amount of rebreathing to take place, easily controlled by rotating the shutter.

I usually induce with ethyl chloride, the shutter being off. I go on as soon as possible to pure ether, the shutter being placed in position and gradually closed down. By this method the patient only breathes a warm ether vapour, a constant depth of anaesthesia can easily be maintained, and the actual amount of ether used is very small. For an abdominal operation lasting one hour, including induction, I use about 6 to 8 ounces of ether-all told.

I have to thank Messrs. Allen and Hanburys for several helpful suggestions and for making this model.

HEAT-STERILIZED SURGICAL DRESSINGS

We have received from Messrs. Southall Bros and Bartholomew Ltd. samples of dressings in sterilized packets which have been sealed by an ingenious new method. The dressing is packed completely, except for a small aperture which is covered by a film of resinous compound. It is then sterilized by moist heat at 125° C. The final drying process, at 130° C., causes the resinous film to adhere to the wrapper and thus to close the packet entirely. This automatic sealing during sterilization avoids any danger of contamination that may arise when packets are sealed after removal from the autoclave.

INFECTION AND IMMUNITY IN
TUBERCULOSIS

The discovery of "Koch's phenomenon," and a disregard of the possible fallacy of comparing man with the highly susceptible guinea-pig, undoubtedly gave origin to the belief that non-fatal infection with tubercle bacilli produced immunity against subsequent reinfection. It is admitted, however, that whilst this immunity prevents rapid generalization it is, as a result of the tuberculin hypersensitivity associated with it, responsible for the destructive form tuberculosis assumes in the chronic phthisical adult. Clinical support for this view seemed to have been obtained when severe and generalized forms were found to be the rule in adults of native races—presumably the result of lack of childhood exposure to infection. When it was demonstrated that a positive tuberculin test proved tuberculous infection it seemed reasonable to assume that a positive test also indicated immunity. Two types of pulmonary tuberculosis were thus differentiated, recently labelled "childhood" and "adult" types by the American National Tuberculosis Association. The former, which is the result of primary infection, usually occurs in children, may be localized in any part of the lung, and involves the corresponding lymph nodes; and caseous lesions usually became calcified. The process results in a positive tuberculin test, and is not uncommonly followed by generalization. The adult type, on the other hand, which is the result of reinfection (whether exogenous or endogenous), usually occurs in adults, and is apical in localization, the nodes are not involved, and caseation is followed by excavation and fibrosis.

Recent work, however, suggests that these conceptions may have to be much modified. Rich¹ has shown that tuberculin hypersensitivity and immunity can exist independently, and that hypersensitivity may be abolished while immunity persists. Research in South Africa² has shown that nearly 70 per cent. of the "boys" arrive at the mines tuberculin-positive, and that "a highly fatal type of combined pulmonary and 'generalized' tuberculosis" is more common among those who were positive—clinical evidence of the disappearance of immunity while hypersensitivity persists. Moreover, recent investigations among medical students and nurses indicate that the response of the adult white to a first infection also differs entirely from that of the negro. Heimbeck³ found that nearly all the Pirquet-negative probationers—about half the number—become positive before the end of their training (during which

they come in contact with over 300 tuberculous patients), and that 29.6 per cent. develop some clinical manifestation of tuberculosis, as contrasted with 2.6 per cent. in those Pirquet-positive. A very large percentage of these "manifestations"⁴ consist of erythema nodosum and pleurisy, and "pulmonary infiltrations" appear to be of the mild childhood type. Greer⁵ found that nearly all the 70 per cent. of nurses who were tuberculin-negative (Mantoux 1 in 100) on entrance became positive, but, since 1930, only three (about 2 per cent.) have developed "tuberculous disease"—two pleurisy with effusion, and one a parenchymatous lesion of adult type. Shipman and Davis,⁶ on the other hand, state that the majority of the 40 per cent. tuberculin-negative nurses (Mantoux 1 in 10,000) did not become positive later, and that most of those who developed clinical tuberculosis were tuberculin-positive on entrance. They point out, however, that their nurses had little opportunity for tuberculous contact. Myers⁷ finds that nearly all the tuberculin-negative medical students at Minnesota University become positive during their training, but that this is accompanied in less than 25 per cent. by symptoms or physical signs (which consist of pleural effusion and/or small x-ray shadows, which soon disappear). Reviewing the subject, he notes that adults tolerate well the first infection type of tuberculosis, and that it differs in little respect from that in children, most of whom also pass through this phase without symptoms other than a positive tuberculin reaction. Naturally a smaller number of such cases are seen in adults (in whom they are detected only by systematic routine examination), and in children miliary and meningitic forms not uncommonly follow. Myers concludes that "the development of rapidly progressive and highly destructive disease in adults who have not been previously infected is apparently a myth." His views therefore support Stewart's⁸ plea for the use of the terms "first infection type" or "primary tuberculosis," and "reinfection type." The latter would probably cause less confusion at a time when the tuberculin sensitization appears to be much lower than is commonly considered.

It is essential to point out the lack of uniformity in the criteria adopted in these investigations as regards the type of tuberculin test employed, definition of clinical tuberculosis, and the opportunities for contact. The last is of great importance also in attempting to answer the question often put as to whether a tuberculin-positive or -negative child or nurse is more liable to "develop tuberculosis." According to the views quoted here the following would appear to be a "working" answer. When both are exposed to massive contagion the negative individual will almost certainly develop a symptomless or mild primary tuberculosis, which may become generalized in a child. The positive individual (child or adult) will perhaps develop

¹ *British Medical Journal*, Epitome, 1927, ii, para. 243.² *Ann. de l'Inst. Pasteur*, 1929, xlii, 1229.³ *Arch. Int. Med.*, 1932, xlix, 77; *Trans. Nat. Tuberc. Assoc.*, New York, 1932, p. 118.⁴ *Amer. Rev. Tuberc.*, 1933, xxvii, 474.⁵ *Ibid.*, 1933, xxix, 93.⁶ *Journ. Amer. Med. Assoc.*, 1933, c, 1077.¹ *Lancet*, 1933, ii, 521.² *Pub. South African Inst. of Med. Research*, Johannesburg, 1932, vol. v, No. 30.³ *Acta Med. Scand.*, 1930, Supplementum No. 34, p. 143; *Presse Méd.*, 1932, xl, 528; *British Medical Journal*, Epitome, 1932, ii, para. 27.

chronic phthisis (exogenous reinfection). This may presumably also occur later on in a primarily infected individual if the contact is prolonged. When there is no source of contagion the positive individual is at a disadvantage, as any lowering of his general or specific resistance may result in chronic phthisis (in both adult or child) owing to the presence of living bacilli somewhere in the body (endogenous reinfection). And clearly there is much more opportunity for lowering of the resistance in the adolescent than in the school child. If a primary tuberculous infection can be said to constitute an *individual* handicap—and prevention should consist in avoiding as long as possible a first infection with *virulent* bacilli—a positive tuberculin test may theoretically prove to be so in another way. B.C.G. vaccination is said to produce tuberculin hypersensitivity as well as immunity. While the vaccinated child would benefit by the prevention of generalized forms, the protected adult, who is not liable to the latter, might after vaccination be at a disadvantage when meeting his first virulent infection owing to this destructive hypersensitivity. It would be of great interest to have full individual details, in addition to numbers, of the tuberculous cases amongst Heimbeck's¹ B.C.G.-vaccinated and non-vaccinated nurses originally Pirquet-negative.

FALLACIOUS GENERALIZATIONS

It seems to us necessary to utter a word of protest about an article which appeared in a recent number of *The Listener* under the title "The Frustration of Medicine." This is the more needed in that the article was written by Professor Mottram. Anything he says is bound to have considerable weight, and should carry with it the assurance of scientific thought and accurate statement. The article in question does not confirm this assurance. Of course nothing written by Professor Mottram can be wholly without value, and in this article he points out the real need for further financial aid for medical research, illustrating this need by several excellent examples of what might be easily accomplished if adequate means were forthcoming. His main theme would seem to be the unfortunate effects of the lag in the practical application of the results of research in the medical field, and of the unscrupulous exploitation of some of those results for commercial rather than for scientific purposes. Here is a subject whose discussion might have been of great interest and value, though the reasons from which this lag arises are by no means necessarily unworthy.

Professor Mottram, however, departs widely from this main theme, and the general effect of a large part of his article on the great majority of his uninformed readers must be to produce a false impression, both as to medical education and as to the knowledge, skill, and even honesty, of general medical practitioners. Here again, of course, it has to be admitted that there are serious defects in medical education (though the

standard attained in this country may be truly described as the highest in the world), and that among the many thousands of general practitioners there are a number who fail to live up to their opportunities. It is, however, unwarrantable, and may indeed be highly mischievous, to build upon these defects or exceptions such general statements as Professor Mottram makes. It is not true to say that "the academic part of the medical student's training is hopelessly inefficient"; that "in ninety-nine cases out of a hundred he sloughs his scientific training when he enters the wards"; that of "biology, chemistry, physics, physiology, and anatomy he gets but a smattering, and of their serious import nothing"; that "only when the medical student is at last in the wards does he come into contact with anything which seems even remotely connected with his life's work." Incorrect, too, is the general statement which Professor Mottram makes that "it is only by a deep critical study of a subject that a man can begin to discover the spirit of scientific work." Happily even more than a beginning can be made by something less than this, otherwise not merely medical education but all general education would be impossible in less than a life-time of study, and then only for a few. Again, as to post-graduate study in some reasonable form, Professor Mottram is unduly pessimistic. He "hails with delight" the establishment of the new post-graduate medical school at Hammersmith, but prophesies that it will be attended only by "medical officers of health whose local authorities have the wisdom to subsidize them, keen private practitioners with private means, and budding consultants." The use made even of the existing limited facilities does not justify any such forecast; and has Professor Mottram never heard of the fund which enables certain insurance practitioners, whose circumstances would otherwise make it very difficult for them, to attend post-graduate courses?

Apart from this erroneous description of the general practitioner's education and of his attitude towards advances in professional knowledge and practice, the one concrete example which Professor Mottram gives of the inadequacy of the G.P. is with regard to the use of insulin in the treatment of diabetes. He says: "The general practitioner has neither the time nor the scientific background to understand the factors at work in producing diabetes nor the relation of insulin to diet and intercurrent disease." We cannot accept this of general practitioners as a class. It is true that the initial experimentation with a view to securing the correct balance between diet and the insulin dosage must in many cases be conducted in hospital, but Professor Mottram knows that this is a relatively short business and that the conduct of these cases is as a rule successfully supervised over a period of years by the general practitioner. Again, as Professor Mottram is not aware that insulin can be, and is, obtained for insured persons as readily as any other drug or preparation, and that the treatment of diabetes amongst such patients by insurance practitioners is a commonplace?

It is no reply to say that such treatment is unsuccessful because diabetics ultimately die.

It would be germane to inquire of Professor Mottram what is the implication of his statements that "no poor person, no one without well-to-do relatives to back him, can easily enter the medical profession: a career is not open to talent unless there is financial backing," and that "at the end of his training he is stranded . . . if he has no private means." Even in the days when scholarships were far less abundant than now these disabilities were frequently overcome; and, though the existence of certain scholarships is admitted in the article, there is no mention at all of the "senior scholarships" of local education authorities which of recent years have been granted, in quite numerous instances, to deserving students with inadequate means to enable them to pursue a medical course. But the statements quoted have no real force unless Professor Mottram believes, as he seems to imply, that everyone who "thinks he would like to be a doctor" and has passed the necessary preliminary tests ought to be supplied from public resources with the funds to go through his medical course and to set up in practice.

THE SWAB IN DIPHTHERIA DIAGNOSIS

A remarkable diversity of opinion and practice is revealed in the correspondence recently published in these columns on the subject of diphtheria diagnosis. Its origin is the allegation by Dr. E. James, supported by Dr. Sanctuary, that the results of swab examinations are so untrustworthy that swabbing were better abandoned. This, of course, should not be so. For a false report the blame may lie either with the practitioner or with the bacteriologist; a false negative usually with the former, since its common cause is failure to apply the swab to the actual site of the lesion. The technique of swabbing is an important factor, and it should be more generally realized that the lesion in diphtheria (when it is not laryngeal or nasal) may affect only a small area on the fauces; the swab should be applied to this and this alone, and not rubbed indiscriminately over a wide area. Likewise a swab heavily contaminated with saliva should be rejected, and the process repeated with another. The false positive may have one of two chief explanations: the patient may be a carrier of diphtheria bacilli and yet be suffering from a tonsillitis due to some other micro-organism; or the bacilli cultivated, although having a typical or suspicious appearance, may be avirulent diphtheria bacilli or diphtheroids. A positive report is the only safe course in doubtful cases pending further laboratory investigation. The errors due to all these causes should not be so numerous as to lend any support to Dr. James's proposal, and the answer to his complaint is better technique both at the bedside and in the laboratory. That the swab has many other uses than the diagnosis of the doubtful acute case we are reminded in the letters of Dr. A. G. Newell and Dr. French. That the laboratory might do more than it usually does to obviate delay, especially at inconvenient hours, when the post serves poorly, and at week-ends, is probably the opinion of many. This is in part a question simply of transport, com-

munications, and working hours; but in one respect it may be a question of technique, and if Dr. Ponder's admirable practice of examining direct films were generally followed, not only would most cases of frank diphtheria receive laboratory confirmation at once instead of on the following day, but fewer cases of Vincent's angina would go unrecognized, as unquestionably they often do at present. This proceeding, however, calls for a greater expenditure of time and a considerably higher degree of skill—if it is to yield the full results of which it is capable—than the ordinary practice of culture alone. The gravest conflict of opinion in this correspondence concerns the clinical aspect of diphtheria and the possibility of diagnosing the disease by its physical signs. The letters of Dr. A. T. Blease and Dr. Newell present a sharp contrast in this connexion, the former insisting that a diagnosis is sometimes impossible on clinical grounds, the latter emphasizing the well-known clinical points of distinction between diphtheritic and streptococcal tonsillitis. We find another divergence of opinion between the letters of Dr. P. R. Wallis and Dr. D. M. Gray: the former contends that if enough suspicion of diphtheria exists to call for a swab examination that suspicion demands the immediate administration of antitoxin; the latter recognizes a class of case in which antitoxin may be withheld until a swab report is obtained. Dr. Wallis would no doubt except from his rule the case in which a swab is only taken as a safeguard against a remote contingency; his proposal is incompatible with the suggestion that all sore throats should be swabbed. To pretend to judge between the conflicting opinions of so many experienced observers is more than we wish to undertake, except to propose the lame though obvious compromise that every case must be judged on its merits, taking into account not only the features of the case itself but the surrounding circumstances. If every practitioner devoted as much thought to this subject as the writers of these letters, it would become evident that diminishing the dangers of diphtheria is less influenced by matters of disputed clinical policy than by alertness and determination to take effective steps of some kind with the least possible delay. This whole controversy is, of course, superseded in importance by the issue introduced in the last sentence of Dr. Newell's letter. Our main business as a profession should not be to cure diphtheria but to prevent it, and if any further public health officers are to be appointed to deal with this problem, as is suggested by Dr. Crawford, prevention should be at least their chief concern. The number of children immunized in this country is still lamentably small, and much more could be done by the practitioner as well as by many public health authorities in advocating timely immunization. That this is an effective proceeding, and not merely safe but often unattended by even slight discomfort, should be preached insistently. Misguided public opinion has a lot to answer for, and in no respect is it more to blame in this country than in its attitude to all methods of immunization; between the ultra-moderns who believe in nothing unless they get it through a hypodermic needle and that large section of the population which maintains an almost religious prejudice against any sort of "inoculation" the common-sense intermediate class is still smaller than in many other countries.

BIOGRAPHY IN MEDICAL HISTORY

Of the six main articles in the July instalment of the *Annals of Medical History*¹ three deal with biography and three more or less with the wider aspects of the evolution of ideas, thus holding a balance on the question whether information about individual leaders and prominent members of the profession, or the progress of medical science, or both combined, should be the real object and ideal use of medical history. Thus baldly stated it is clear that medical history should be primarily devoted to consideration of fundamental principles and the development of ideas. But this is not all; the record of a man's life may be small beer and gossip, which, however attractive to the casual reader, is not of any permanent value, whereas the biography of a Hunter, Harvey, Pasteur, Lister, or a Virchow may describe and explain the birth and gradual growth of new conceptions and solid discoveries. In the case of science it would not be impossible to expand Thomas Arnold's definition of history generally as the biography of nations. The personal interest may be combined with the history of the achievements initiated or furthered by the individual. Thus the first article in this number of the *Annals*, that by Dr. Birkhaug of Paris on Albert Léon Charles Calmette, which may be included among the three of a biographical character, sets out the record of his work on tuberculosis, the history of the *Bacillus Calmette-Guérin* (B.C.G.), the invention and success of antivenin serum, and his recent work on cobra venom and its cytolytic action, with its possible application to human malignant disease. The graphic account of his persecution by the Germans when they captured Lille shows that there is an exception to prove the rule that science has no frontier boundaries. In contrast to this are the lives of two American practitioners, eminent in their, but not in all, time. The first, Walter Brashear, was a brilliant surgeon who, after an adventurous visit to China, declined a chair of surgery in Paris and retired thirty-six years before his death at the age of 84 in 1860 in order to make a fortune, first in politics, then in trade and planting in Louisiana, and was never a writer or a teacher. Dr. Guy Hinsdale's biographical note on the second, J. P. Moorman, gives the details of a resident physician at the White Sulphur Springs, Virginia, for the long period of forty-five years; he sat for two terms in the Virginia House of Delegates and for forty-five years was an elder in the Presbyterian Church. In his article on men and events in the history of the Philadelphia Pathological Society Dr. David Riesman combines many thumb-nail sketches of its presidents and of a few honorary members with a review of the changes that pathology has gone through in three-quarters of a century. Of one honorary member he says: "Virchow did for pathology what Vesalius did for anatomy." The influence of the Paduan professor's *De Humani Corporis Fabrica* on anatomy can be judged by Dr. W. T. Dempster's account of European anatomy before Vesalius. Another useful article is Dr. A. E. Fossier's history of medical education in New Orleans from 1834.

MALARIA IN TRINIDAD AND TOBAGO

In a recent public lecture at Port-of-Spain Dr. E. de Verteuil, acting deputy surgeon-general, described the malarial survey of Trinidad and Tobago which began in 1930, and which had revealed a high spleen and parasite rate in several areas. Atebrin had been found effective in destroying the parasites inside the human host. While pond breeding places had been brought under control, the problem of dealing with the rice fields remained for solution. In Indian settlements and native villages a high degree of immunity seemed to have developed, but until the mangrove swamps had been attacked such towns as Port-of-Spain were riddled with malaria. Some of these swamps still persisted, and called for eradication. A similar process of land reclamation and parasite control had been extended along the shores, rendering it possible for new villages to come into existence without increasing the liability to infection. For the last three years special attention had been directed to the rice fields. Drainage operations were now being conducted with a view to the abolition of breeding places, and considerable success had been achieved, especially in those detected near the larger centres of population. These had resulted also in the improvement of the general sanitation, the provision of recreation grounds, street widening and the opening up of crowded areas; and the relief of housing congestion in certain parts of Port-of-Spain. Tobago still needed energetic treatment, for the malarial strains there were particularly virulent. Only a few swamps would have to be dealt with to ensure the permanent extinction of the disease in a year or two.

THE SPLEEN AND CARBOHYDRATE METABOLISM

The modern conceptions as to the function of the spleen do not in general include that of an endocrine organ. The suggestion was recently put forward by certain Japanese workers that the spleen had an anti-parathyroid function, the removal of the organ in rabbits leading to a marked increase in serum calcium: injection of splenic extracts were reported as diminishing it. This work has not as yet been confirmed, and it is not easy to reconcile such findings with either the histological structure of the organ or the results of its ablation in man. The possibility of some connexion between the spleen and sugar metabolism was put forward as long ago as 1924 by Charles Richet and some of his pupils. Thus Rathery found that the extirpation of the spleen in dogs led to a more or less persistent rise in free and combined carbohydrate in the blood, suggesting that the spleen might contain or elaborate an insulin-like substance. That a certain amount of insulin may be extracted from tissues other than the pancreas is well known, but the results of Rathery were interpreted as indicating the presence of a substance other than insulin. More recently Piessinger and his co-workers have reopened the question, and in a new series of experiments Rathery, Cosmulesco, and Grignon¹ re-examine the problem. These authors used an extract of spleen and followed the effects on the blood sugar of dogs after intravenous injection under

¹ *Presse Méd.*, June 13th, 1934.

various conditions. Details of the preparation of the extract are not given, but it appears to have been obtained by simple defatting and deproteinizing the splenic tissue. Having satisfied themselves that the blood sugar depressing effect was demonstrable in dogs, they proceeded to try it on diabetic human subjects, 2 c.cm. of the extract being injected intravenously. In eight out of ten cases the injection was followed by a more or less marked fall in blood sugar, the maximum fall being reached about one and a half hours after the injection, and the original level again in some two to three hours. In association with insulin the spleen extract seems to accentuate the insulin action. The suggestion is made that it might be useful to combine insulin injection with that of spleen extracts in certain cases of diabetes. The possible existence of a sort of activator of insulin in the body has been put forward recently by Himsworth, and it may be that the splenic extract here considered is of importance in this connexion. In none of the cases of diabetes treated with the spleen extract was there any question of hypoglycaemia, the fall in blood sugar rarely exceeding some 30 to 40 mg. per 100 c.cm. No suggestion is made (perhaps wisely) as to the mechanism of action of the spleen extract.

THE NATION'S FOOD SUPPLY

The Food Investigation Board, which has as its primary object the improvement of the food supply for the people of this country, has always followed the practice of according precedence first to home-grown, then to Empire, and finally to foreign produce. In its annual report, issued on August 20th by the Department of Scientific and Industrial Research, are reviewed the aims of the research work, now costing some £45,000 a year, which has been carried out on the transport and storage of foodstuffs. For example, the Torry research station finds that the period during which fish can be kept in first-rate condition on a trayler by the customary method of stowage in crushed ice can be extended from five to seven days to ten to twelve days. Work has also been done on the herring, with a view to improving the smoking of this fish and the production of a milder salt-cured herring. The latter has been obtained by a compromise between salting and cold storage. One interesting point emerges here—that kippers made from herrings which have been rapidly frozen in cold brine and then stored at low temperature for as long as four months are barely distinguishable from kippers made from the freshest fish. As regards meat storage, investigation has shown that beef can be maintained in perfect condition in the chilled state for sixty to seventy days in a 10 to 20 per cent. atmosphere of carbon dioxide, so that, providing gas-tightness can be secured in ships' refrigerated spaces, it would be possible to send Australian and New Zealand beef to this country in chill. Bacon cannot be stored successfully for any length of time by cold alone, and experiments have shown that this difficulty may be to some extent solved by the use of a complete atmosphere of carbon dioxide. Fruit storage is a somewhat complicated problem, and the best temperature for each variety can be found

only by careful trials. There are now twelve gas stores for apples in this country, and several more are in course of construction. Most of them are intended for England's most important cooking apple, the Bramley seedling. It is interesting to note that the correct atmosphere for these apples can be obtained by allowing them to produce their own carbon dioxide and controlling its amount by regulating the ventilation. Empirical storage trials should yield much important information as to the possibilities for other apples, and considerable progress has been made during the last two years with Cox's orange pippin. The flavour is, however, apt to be elusive: in this apple full flavour is not developed after effective gas storage until the fruit has been subsequently kept in air at ordinary room temperature for several days. Further research is being undertaken on these points. Other activities of the Food Investigation Board include work in an experimental ship's hold at the Ditton laboratory. This is designed to improve conditions under which food-stuffs are carried on board ship.

CONTROL OF TRAFFIC IN NARCOTIC DRUGS

The annual statement prepared by the Home Office for the League of Nations on opium and other dangerous drugs¹ reports that during 1933 there were no considerable seizures nor indications of illicit traffic in Great Britain, and repeats the assurance that "drug addiction is not prevalent" in this country. The alkaloids codeine (methyl-morphine) and dionin (ethyl-morphine) have now been brought under control as regards manufacture and distribution, import and export. Last year 35,890 ounces of codeine were produced and 23,366 ounces exported direct by the manufacturers. Great Britain is innocent of production of raw opium, prepared opium, Indian hemp, and coca leaves. Cocaine is, however, permitted to be manufactured by one firm in London, and last year 16,023 ounces were so produced. Two firms, both in Edinburgh, are licensed to manufacture morphine, and 30,757 ounces of morphine alkaloid and 44,169 ounces of morphine salts were produced last year. It has, however, to be remembered that morphine is largely used for conversion into codeine, 26,089 ounces having been so utilized in 1933. The export of British-made morphine was less than in the previous year and greatly less than was the case only a few years ago; 16,156 ounces were exported in 1933. While the story of unmasking illicit traffickers in narcotics in this country is not as dramatic as that related by Russell Pasha in Egypt, two cases of interest are noted in the Home Office report. One arrest in September, 1933, made by the London police on information from Canada of a trafficker in opium when landing, disclosed that the illicit supplies were derived from one Karl Jorgenson, a Norwegian resident in Belgium, who has since been expelled from that country. In the other case Gandarillas, a Spanish subject, was found, on landing at Southampton from Havre on a transatlantic liner, to be in possession of 140 lb. of opium. Communications with the German police traced the source of this

¹ The Traffic in Opium and Other Dangerous Drugs. Report to the League of Nations by His Majesty's Government in the United Kingdom of Great Britain and Northern Ireland for 1933.

contraband to one Otto Janffmann of Hamburg, who was found to be identical with the well-known trafficker Edward Bender, who, when released on bail in America, had fled to Europe. According to the latest information Bender is awaiting trial in Hamburg for offences in connexion with narcotics among others. The new draft convention for the suppression of illicit traffic in dangerous drugs is now being submitted by the Council of the League of Nations to the various Governments in an amended form; twenty-three Governments have thus far indicated approval, while the United States and South Africa have intimated that they are not prepared to participate in the new Convention.

ENGLISH HOSPITAL DEVELOPMENTS

The Quarterly Bulletins of the Health Organization of the League of Nations can be relied upon to contain valuable and accurate summaries of national or international health activities in some part of the world which form material for the information and guidance of other responsible health authorities. Extract No. 8 of volume iii of these Bulletins, now published as a separate pamphlet under the title *Recent Tendencies in the Development of General Hospitals in England*,¹ is no exception to this rule. It is compiled by Dr. Melville D. Mackenzie, a member of the Health Section of the League of Nations secretariat, and is a model of accuracy, selection, and arrangement. It is in two parts, the earlier dealing with matters of hospital administration, the later with those of hospital construction. Neither part contains much that is not known to those who are actively associated with either of these aspects of hospital work, but nowhere else, within relatively small compass, can be found such a complete and reliable survey of these fields. The work of the British Medical Association in relation to hospital policy and administration is acknowledged and adequately set out in relation to medical staffs, pay-beds, provident schemes, contributory schemes, out-patient departments, and the collaboration between voluntary and council hospitals. The peculiar position of nursing homes in the English system is described, and the ways in which they are beginning to be brought under regulation by local authorities are noted. In this connexion the "home hospitals" mentioned in the Association's Scheme for a General Medical Service for the Nation are referred to, and some of the reasons which make such provision necessary are stated. The question of establishing or continuing special hospitals for chronic cases only is discussed, and the particular needs of maternity, of mental, and of infectious cases are not overlooked. There is in the pamphlet no advocacy of any particular policy: it is an impartial statement of prevalent ideas, views, and suggestions. As such, it forms a most valuable, and almost indispensable, basis for further discussion by committees or at conferences which, during the ensuing year, will be considering some or all of these aspects of hospital work with a view to early and practical application.

PUBLIC HEALTH IN SOUTH AFRICA

Science, it is said, knows no frontiers, and so medicine, as a science, is one the world over. Nevertheless, according to latitude and the like, its occasions differ, and even without passing the frontiers of the British Empire we find the widest variety in the scope and method of its applications. Thus in the Union of South Africa it is, as here, recognized that every medical practitioner should be trained in preventive medicine, and yet the climate and conformation of the country, its racial make-up, and its endemic diseases all raise problems which differ notably from those encountered in England. A work on public health in the Union, issued by Dr. E. H. Cluver¹ at Johannesburg, brings out these points well, and presents a most informative picture of the duties and the opportunities alike of the practising doctor and the medical administrator in that sunny land. The essentials of meteorology, ventilation, lighting, water supply, and nutrition are stated with exemplary clearness. The view is expressed that in South Africa indoor fires are an unhygienic luxury, and the question of plumbo-solvency is treated more in the interests of the water-pipes than of the human subject. The importance of town planning is urged, pre-planning for the growing towns, re-planning for those which have grown awry. Special merit belongs to the section on the prevalent communicable diseases, including the control of typhoid fever, with its H and O agglutinations; of plague, now enzootic among veld rodents; of small-pox, which has not been epidemic since 1881; and of typhus, which is an endemic infection of the Transkei and Ciskei natives. Rabies is enzootic in the yellow mongoose. Of leprosy there are over 2,000 cases in institutions. Tuberculosis in the mines is ascribed not to silica but to sericite. Malaria prevails along the Natal coast and in the low veld of the Transvaal, and schistosomiasis is widely endemic in the lands drained by the eastward-flowing rivers. Dr. Cluver's book reveals the wide range and interest of medical practice in South Africa. It is intended primarily to meet the requirements of medical and D.P.H. students in the University of Witwatersrand. They could not, we think, be better served. It should make also, as suggested in a foreword by the Chief Health Officer of the Union, a wider appeal to doctors and medical and lay public health workers, who will derive from it sound doctrine and valuable guidance to aid in deciding what course to follow in an hour of stress.

Sir George Seaton Buchanan has been appointed Master of the Society of Apothecaries of London for 1934-5, and Sir William H. Willcox and Dr. J. S. Fairbairn, Senior and Junior Wardens, respectively, for the same year.

We regret to announce the death in Copenhagen, on September 1st, of Professor Carl Olaf Jensen, director of the Danish Agricultural and Veterinary School, whose name is known throughout the world for his researches on cancer.

Nova et Vetera

THE MEDICAL AND MENTAL HISTORY OF DR. SAMUEL JOHNSON

Dr. W. Russell Brain, writing as a physician and neurologist, has contributed to the May number of the *London Hospital Gazette* a valuable paper on the medical history of Samuel Johnson. He calls his essay "A 'Post-Mortem' on Dr. Johnson" and read it to the Osler Club. It is much more than an anamnesis of an autopsy, for Dr. Brain considers some aspects of his subject which could not possibly be discovered after death—aspects which throw a new light on the mentality of one who dominated the literary circles of his generation and yet himself suffered from an inferiority complex.

The main outlines of Dr. Johnson's bodily health are well known. He had tuberculous glands as a child, and Queen Anne "touched" him for their cure. He suffered from such a high degree of myopia as to be practically blind in one eye. He was so hard of hearing that in later life he sat in the gallery at St. Clement Danes as close as possible to the pulpit. He suffered so severely from indigestion that he once wrote to Mr. Hector, whose sister was his first love, "My health from my twentieth year has been such as seldom afforded me a single day of ease." He had more than one cerebral thrombosis, and late in life he had asthma. A post-mortem examination was made in the presence of Drs. Heberden and Brocklesby and Mr. Cruikshank. The record exists, and from it, in the light of modern knowledge, Dr. Brain says:

"The pathological findings would appear to be due to hyperpiesia and chronic heart failure, ischaemic kidneys, chronic emphysema, and cholecystitis. Some writers have assumed that Johnson's asthma was bronchial asthma. This is unlikely, in view of its late onset; and his dyspnoea seems to have been due at first to emphysema and later to 'cardiac asthma'."

The most interesting and wholly new part of the essay is that dealing with a psycho-analysis of Dr. Johnson, and it gives much food for thought. Dr. Russell Brain, speaking as a neurologist, says:

"Johnson's physical infirmities were probably less distressing to him than his disorder of mind, of which the most obvious manifestations were his remarkable involuntary movements. . . . His gesticulations, like most of his other characteristics, were on a large scale. At times he would hold his hands at his breast in motion 'like those of a jockey at full speed.' He would stretch out his arm with a full cup of tea in his hand in every direction, to the alarm of his immediate neighbours. 'Sometimes,' says Miss Reynolds, 'he would twist himself round with his face close to the back of his chair and finish his cup of tea, breathing very hard, as if making a laborious effort to accomplish it.' He went through complicated manoeuvres with his feet, and had to carry out an elaborate ritual of movements before he would pass through any door. Sometimes he would stop in the street to gesticulate. . . . One Sunday morning in Twickenham Meadows his antics caused a crowd to collect. When he sat down by the river they nearly dispersed, but 'he pulled out of his pocket Grotius' *De Veritate Religionis*, over which he saw-sawed at such a violent rate as to excite the curiosity of some people at a distance to come and see what was the matter with him."

"Another symptom of his mental abnormality was his melancholy, which, in his own opinion, he inherited from his father. He seems to have first suffered from this when at Oxford at the age of 20. . . . He had a particularly severe attack when he was 56. . . . His fear of death was a constant obsession, and was probably the cause of that hysterical outburst of laughter which was aroused by Langton's making his will. He sat up late at night to avoid being left to himself. 'I lie down (said he) that my acquaintance may sleep; but I lie down to endure oppressive misery; and soon rise again to pass the night in anxiety and pain.' Yet Fanny Burney could say of him, 'Dr. Johnson has more fun and comical humour about him than almost anybody I ever saw.'"

"What was the nature of his disorder of mind? Was he, as he himself, to Boswell's distress, said, 'mad all his life, at least not sober'? Periodical melancholy, or at least depression, naturally suggests manic-depressive psychosis. Yet there are several reasons for believing that Johnson's depression was not due to a psychosis. The most important

is that to a large extent his lowness of spirits could be dispensed by distraction of mind, which leaves psychotic depression untouched. He himself practised distraction of mind as a cure for melancholy, and often recommended it to others. An amusing example of his method is given by Mrs. Piozzi. . . . When Dr. Johnson felt his fancy, or fancied he felt it, disordered, his constant recurrence was to the study of arithmetic; and one day that he was totally confined to his chamber, and I inquired what he had been doing to divert himself; he showed me a calculation which I could scarce be made to understand, so vast was the plan of it and so very intricate were the figures: no other indeed than that the National Debt, computing it at one hundred and eighty millions sterling, would, if converted into silver, serve to make a meridian of that metal, I forget how broad, for the globe of the whole earth, the real globe."

Johnson's melancholy, like his gesticulation, was a symptom of his severe obsessive-compulsive neurosis, says Dr. Russell Brain, and he concludes a very valuable essay by considering what Freud, Adler, and Jung would have made of Johnson. Freud, he thinks, would fit him in the somewhat Procrustean bed of Jocasta. Johnson's wife, old enough to be his mother, must surely have been a mother-substitute, and Mrs. Williams, Mrs. Desmoulins, and the other queer old ladies with whom he lived in a kind of platonic polygamy would have held a similar position. Adler would regard Johnson as a man of exceptional ability suffering from the fatal psychological handicap of several forms of inferiority; his physical defects of poor vision and facial disfigurement, his lack of comeliness relative to his younger brother, and his hampering poverty must all have been thorns in his flesh when he considered his intellectual capacity and what he might have been had it not been for these handicaps. Jung would classify him in the group of "thinking extroverts."

"In his religion intellectual dogmatism seems to have taken the place of mystical experience, and he was racked by a sense of guilt which made the thought of death an intolerable obsession. . . . Though in no sense a Pharisee, yet psychologically he was a whitened sepulchre, without—the *Thirty-nine Articles*, within—the dead men's bones of pessimism, terror and despair."

Dr. Brain's final picture of Johnson is that of a man of genius, harassed by physical infirmity and mental ill-health, failing to find adequate employment for his talents and satisfaction for his ambitions, yet triumphing over all handicaps and achieving an immortality in human affection that would have been denied to the successful politician or lawyer he might have been.

THE PORT OF LONDON IN 1933

General interest attaches to many parts of the annual report for 1933 of the medical officer of health for the Port of London, the extent of which is from Teddington Lock to the entrance of Havengore Creek in Essex and the Warden Point in Sheppey. The tonnage of entering vessels exceeded that of 1932 by more than 1,239,000 tons. Of the 13,575 vessels arriving from foreign ports 1,600 were inspected by medical officers. No case of plague arrived, and no plague-infected rats were found in any ships or on shore in the Port. Under the new sanitary regulations of 1933 a total of 1,027 certificates were issued in respect of deratization; the paper read last year before a meeting of the Association of Port Authorities by the medical officer of health on the rat-proofing of ships is reproduced. In it Dr. C. F. White indicates the main lines of this work, such as the opening up of pipe casings and the stopping of rat runs. He urges that the correction of rat harbourage should be indicated on certificates by the words "eliminated" or "protected," as the case may be. When harbourage has been really eliminated, the word "none" should appear in the rat-harbourage column of subsequent certificates. The Port of London Authority has issued instructions that all new work is to be structurally rat-proof. Dr. White concludes this section of his report by remarking that, although to some small extent *X. cheopis* fleas are found on ship rats in the Port, it is very rarely that they persist ashore. They certainly

do not multiply on the shore rat population, and if the spread of rodent plague ashore depends on the *X. cheopis* the Port of London should be practically immune from any danger of a rat epizootic.

SHIPS' WATER SUPPLY

Ships usually obtain water from the shore supplies afforded to the docks by the Metropolitan Water Board and the South Essex Water Company, but when no water is available at the berth, or the ship is lying at moorings in the river, the supply is drawn from water boats, of which there are twelve working in the Port. Every care is taken to avoid pollution of all the sources, but in August, 1933, an outbreak of enteritis on a ship in the Mediterranean was traced to the end of a canvas hose attached to a tap on a quay. It was found that samples from the end of this hose, but from nowhere else, contained coliform bacilli, although no true *B. coli* were recovered. It is concluded, therefore, that coliform organisms may gain access to pure water during its passage along a length of hose to a ship, and will, under favourable conditions, multiply during storage in the ship's tanks. These bacilli are not pathogenic, but they indicate the possibility of dangerous contamination. Dr. White adds the caution that in such cases it is important to discriminate between the true *B. coli* and coliform bacilli—a distinction which is not always made. He does not think that bacteriologists should unhesitatingly condemn a sample of water from a ship merely because coliform bacilli are present. Doubt should be expressed about the sample without a final condemnation. Coliform bacilli are probably present in the majority of samples of water from ships, but outbreaks of water-borne disease on ship-board are very rare: he remarks that it is very doubtful whether the outbreak of enteritis in this ship was actually due to the water supply, and that it is certain that the water supplied in the Port of London is above suspicion.

BOARDING OF VESSELS ON ARRIVAL

Dr. White hopes that some day the routine boarding of ships from infected ports will be discontinued, and in its stead there will be boarding of ships carrying cases of infectious disease and also any case of sickness which might conceivably be of an infectious nature, though not actually diagnosable as such. The port medical officer should be the person to carry the responsibility of deciding whether a case might possibly prove to be infectious. Many cases of typhoid fever, some of small-pox, and a few of plague have been landed in this country as "influenza"—a diagnosis which should always be regarded with suspicion by every medical officer. When a ship arrives which has on board a case of one of the major infectious diseases, or on which such a patient has died or has been landed abroad within the incubation period of that disease, it is the practice to regard every person on board as a contact and to arrange for his supervision. Those intending to leave the ship are required to give their names and future addresses before leaving, for it has been found useless to extract this information from the passenger manifest and the crew's articles. The introduction of a double postcard, one half for the notification of the immediate address and the other for notification of any change of address, has proved very successful in expediting the clearing of ships and the transmission of the necessary information to the medical officers of health of the districts of destination, and in making passengers realize their obligations under the regulations. The section for notifying change of address is on the "business reply card system," so that the passenger need not stamp it. The efficiency of the system was indicated by an instance when 289 such cards were issued and only one address could not be traced.

The Treasury has recently made, on the recommendation of the Advisory Committee, the Additional Import Duties (No. 28) Order, 1934 (S.R. and O., 1934, No. 921), under which the Customs duties on medical, surgical, dental, veterinary, and dissecting instruments and parts thereof will, as from August 25th, be at the rate of 20 per cent. ad valorem.

THE TWELFTH INTERNATIONAL VETERINARY CONGRESS

This was held in New York during the week beginning August 13th, under the presidency of Dr. JOHN R. MOHLER, chief of the United States Bureau of Animal Industry. It was attended by approximately 3,000 delegates from about sixty different countries—nearly twice as many as had attended any previous congress. This is the first occasion it has taken place in America, the last congress, as readers may recall, being held in London in 1930 (see *Journal*, August 16th, 1930, p. 259). During the course of the congress many topics relating to medicine and comparative medicine were discussed, and we give below a selection of those of more immediate medical interest.

ANTHRAX

On Monday afternoon (August 13th) Dr. MARIO MAZZUCCI (Italy) described his new method of vaccinating animals against anthrax. This method aims at localizing bacilli with a certain degree of virulence at the site of inoculation and attaining the slow absorption of an antigen with a high immunizing power. To do this he injects the organisms simultaneously with saponin ("carbozoo" vaccine) in order to bring about a gelatinous oedema around the injected bacilli. In sheep an immunity is still noticeable five months after vaccination, although this immunity is not observable before the ninth or tenth day. He claimed that this method of vaccination was a harmless and effective means of clearing up enzootic hotbeds of the disease, over two million animals having been treated in Italy alone in this way. Dr. VIDAL MUNNE (Spain) believed that immunity in this disease was possible only when the bacteria reproduce at the site of inoculation and there form capsules, and he concluded that intradermal inoculation is most efficient.

INFECTIOUS MASTITIS

Professor STECK (Switzerland), on the same afternoon, introduced a discussion on infectious mastitis. He held that the disease in cattle could be effectively controlled only by eliminating infected animals (by fattening and slaughter), by separation of all less seriously infected animals, and by chemotherapy to minimize the spread of the infection and shorten segregation. He believed that the repeated use of antiseptics such as the acridine derivatives gave an efficacy of over 90 per cent. Dr. MINETT (Royal Veterinary College) discussed streptococcal mastitis from its bacteriological and preventive medicine viewpoint. The disease was mainly caused by *Streptococcus agalactiae*, although two strains of haemolytic streptococcus were sometimes also involved. The latter were very similar to the human *Streptococcus pyogenes*. As a rule they did not cause disease in man, although human strains were occasionally seen in mastitis and were especially dangerous. The disease could be effectively controlled by milking infected cows last. Dr. SVEN WALL (Sweden) discussed mastitis due to *Diplococcus schütz*, and Professors CHRISTIANSEN and NIELSEN (Denmark) considered the methods by which cattle became infected. They concluded that under natural conditions this was always by the teat canal, although they admitted that some undiscovered factors existed which governed the entrance of the bacteria. Drs. JONES and LITTLE (U.S.A.) agreed. Their experiments indicated that the udder became sensitized by one or more preliminary infections which did not result in disease.

VETERINARY SANITATION

On Tuesday morning (August 14th), at a general session of the congress, a paper by Professor LECLAIRCHE (France) was read on State veterinary sanitation. The old methods which had already conquered—at least partially—many important diseases, such as glanders, rabies, anthrax, and various others, were insufficient against such widespread infections as tuberculosis, Bang's disease, and so on. Eradication of these was at present impracticable, and it was sought instead to limit the losses to a supportable

economic total. He expressed himself in favour of using only healthy stock to build up herds and to replace unprofitable animals, and advocated the issuing of State certificates of health, which would guarantee not only that the animals were free from disease themselves, but that they came from healthy herds. He opposed hasty methods of eradication as likely to lose the confidence of the stock owner. At the same session Dr. MOHLER, chief of the Bureau of Animal Industry (U.S.A.), discussed the relation of veterinary science to animal breeding and public health. In connexion with the latter he stressed the importance of meat inspection and of veterinary supervision of animals at the time of slaughter, of improvement in milk supplies, and of the value of research on animal diseases in providing information of value for the betterment of mankind.

PSITTACOSIS AND WEIL'S DISEASE

On Tuesday afternoon Professor MEYER (U.S.A.) discussed the 1931 outbreak of psittacosis, which took place in parakeets in California. The casual agent was a filterable virus, transmissible to a number of other species of birds and to man. Since 1929, 143 human cases had been definitely diagnosed in North America. United States health regulations now required certificates of health and other precautions to be taken before parakeets were transported anywhere. At the same session Dr. KLARENBECK (Holland) drew attention to the frequency of Weil's disease in dogs in Holland, and its importance in these animals, because of their intimate association with man. It was the more important on account of the difficulty of diagnosis in the dog and the variability of the symptoms which it caused.

TUBERCULOSIS

On Wednesday morning (August 15th) Dr. E. A. WATSON (Canada) introduced a discussion on tuberculosis. He had studied the B.C.G. method of vaccination over a period of ten years in a dairy herd of ninety cattle, fifty-four of which had been vaccinated, thirty-six acting as unvaccinated controls. All were equally exposed to natural infection, and on necropsy the incidence of tuberculosis was exactly the same—83.4 per cent.—in both groups. The anatomical distribution of the disease was similar in both groups, but in the vaccinated animals the lesions tended towards caseous, caseo-purulent, and exudative processes, with appreciably less fibrosis than in the unvaccinated group, in which caseo-calcareous lesions predominated. The critical age was between puberty and maturity—that is, 2 to 4 years in cattle—when the increased relative resistance attributable to B.C.G. vaccine was seen to fail rapidly and to disappear. Dr. GUÉRIN (of the Pasteur Institute, France) said that since the last congress in 1930 no fresh observations had been made which would give rise to the hope that a new approach to the problem of tuberculosis prevention in cattle might finally be found, and our two conceptions of prophylaxis were still based on (1) the use of tuberculin and (2) the production of a state of allergy. He believed that the production of an allergic state by the use of B.C.G. furnished a resistance to subsequent infection with virulent tuberculosis, and that it was of great value in controlling the disease. He considered that it was useless to try to eradicate the bacillus, and that we must aim at preventing its effects; further, that we must give up the idea of slaughtering all animals reacting to the tuberculin test, and concentrate on producing resistance to the disease. Dr. WIGHT (U.S.A.) described the campaign to eradicate tuberculosis in the United States, and stated that about 65 per cent. of the cattle in that country were now under supervision. Already 130 million tests had been made, and three million reactors had been destroyed. Dr. ZWICK (Germany), while expressing admiration of the American work, did not believe that it was practicable in Europe. In Germany they used the Ostertag plan, which aimed at the elimination of contagious cases. That this system was valuable was beyond doubt. He considered that the B.C.G. vaccine was still in its experimental stage, and stated that the tendency in Germany was to be cautious. Professor BASIL BUXTON (Cambridge) described the Cambridge experiments on B.C.G., which were commenced in

1927 and were still continuing. These results indicated that the vaccine could raise the resistance of a calf to a virulent experimental infection. The degree of resistance varied considerably, and appeared as a rule to be directly proportionate to the dose of vaccine. Experiments were now in progress to ascertain whether repeated vaccination at proportionate intervals over a period of years would maintain the resistance of cattle to reinfection with virulent bacilli.

IMMUNITY TO PARASITES

On Wednesday afternoon Professor T. W. M. CAMERON (McGill, Canada) discussed the question of immunity against animal parasites. He believed that the resistance mechanisms of the body against animal parasites did not differ in principle from those evoked against bacteria and viruses, but their method of attack was so different that their manifestations were often altered considerably. Our present knowledge of the subject was still fragmentary and confusing. It seemed possible, however, to summarize our existing knowledge in the following terms. Animals were *naturally immune* to parasites of physiologically unrelated animals, although a few worms appeared to have very wide physiological requirements—for example, fasciola, trichinella, and the larval stages of *echinococcus*. In certain circumstances *natural immunity* may be broken down. Animals were *naturally tolerant* to the effects of their own parasites, but this tolerance could easily be broken down by adverse factors. They were much less tolerant to abnormal parasites. Animals often become *premune* to their own parasites; this premunition might be broken down by unnatural factors such as lack of food, overcrowding, other parasites, and so on. This was a common method of resistance to protozoa; we were less sure of its operation against metazoa. Animals were sometimes susceptible to parasites proper to physiologically related animals; an age resistance was often shown to these as it was to other abnormal or recently introduced species. The evidence for breed immunity was still very scanty. There was little evidence yet of a true *acquired immunity* against adult helminth parasites, and, although theileria produced a sterile immunity and the coccidia might do so, premunition was, in general, the usual means of resistance among the protozoa. In practice an artificial premunition can be produced only against babesia. It seemed probable that hypersensitiveness was a normal defence reaction of the body. The phenomenon had been successfully used in diagnosis. Some of the serological changes observed appeared to have no necessary connexion with defence reactions, but some had. There was no evidence (with the doubtful exception of sarcocystis) that any of the animal parasites produced a true toxin, and the "foreign proteins" introduced by them into the body were probably normal secretions and excretions. If antibodies produced in response to normal secretions inhibited their actions, they might well prevent parasites from securing and digesting food, and consequently act as a mechanism of resistance. Other antibodies, especially in the protozoa, acted by interfering with reproduction, possibly in a somewhat similar way. The eosinophils, evoked in response to the presence of foreign proteins, seemed to play an active, but as yet improperly understood, part in the defence against metazoan parasites and their effects.

MILK MARKETING

On Thursday morning (August 16th) Dr. VON OSTERTAG (Germany) introduced a general discussion on the marketing of milk. As wholesome milk, he declared, could only be derived from healthy cows veterinary milk control was essential. Milk must not be marketed from cows with udder or "open" tuberculosis, but the question of the transmissibility of *Brucella* through milk required further investigation. Milk should not be considered dangerous in cases of European mastitis caused by *Streptococcus agalactiae*, in contrast with American mastitis caused by *Streptococcus pyogenes*; it was sufficient to exclude milk which had undergone changes. Milk from animals infected with one of the paratyphoid enteritis organisms must receive particular attention, owing to the dangers of human infection.

VIRUSES

At the same session Dr. MANNINGER (Hungary) introduced a discussion on filterable viruses, which he considered should be called "ultra-viruses," because of a filterable phase in the life cycles of some bacteria. They could be grown *in vitro* only in the presence of living cells—especially active cells. For the most part they caused exceedingly contagious diseases, although a few did not, and many gave rise to cell inclusions. Dr. GERLACH (Austria) commented on their striking resemblance to true enzymes and the unique position they held with regard to their antigenic behaviour. Viricidal power might be demonstrated almost regularly in their antibodies, and it was possible that these were closely related to the antitoxins and antiferments. After recovery from disease the supervening immunity might be of long duration and high titre.

CONTAGIOUS ABORTION

In a discussion on Brucella disease which followed Professor BANG (Denmark) declared that in northern Europe only *Brucella abortus bovis* had been demonstrated in human undulant fever, and that as the bacilli

do not multiply in the milk after it is drawn from the udder, mixed milk will usually contain only a small number of the organisms. Dr. COTTON (U.S.A.) described a nation-wide plan in America to reduce the condition by testing and slaughtering reacting animals. Dr. FINZI (Italy) discussed the desirability of standardizing the biological tests for the organism. He believed that there was a future for chemotherapy in the fight against Brucella infections, and that while live vaccines were dangerous dead vaccines were almost useless.

ANIMAL PARATYPHOID AND PUBLIC HEALTH

In the afternoon Dr. CLARENBURG (Netherlands) opened a discussion on the paratyphoid diseases of animals in relation to public health. Complete absence of danger to man could not be claimed for any of the animal salmonellos, and any meat from any animal harbouring the organisms was potentially dangerous, as well as infected milk and eggs. He advocated compulsory notification of salmonellos of animals, and minute differentiation of Salmonella occurring in man and animals. Dr. MURRAY (U.S.A.) and Dr. STANDFUSS (Germany) discussed the classification of the group in some detail, based on their reactions in various carbohydrate media.

France

[FROM OUR CORRESPONDENT IN PARIS]

The late Professor Léon Bernard

An international as well as a national leader of medicine has been lost in Léon Bernard, professor of tuberculosis at the University of Paris. His conception of a holiday was change of work, preferably in moving about from place to place, inspecting in France the many tuberculosis activities with which he was connected. A serious motor car accident a few years ago arrested his zeal only momentarily, and he was in the full exercise of all his faculties when, in the latter half of August, at the age of 62, he was admitted to a nursing home in Clermont-Ferrand on account of a dental abscess whose evolution proved fatal in a day or two. Médecin des Hôpitaux de Paris, Léon Bernard succeeded Chantemesse in 1919 in the chair of social hygiene in the Faculty of Medicine. Subsequently, he became clinical professor of tuberculous diseases. He was president of the Conseil Supérieur de l'Hygiène Publique, and the permanent delegate of France on the Health Committee of the League of Nations. His publications covered a wide range, and some of the most important were those concerned with public health. Holding a commanding position at the Laennec Hospital in Paris, he extended his tuberculosis activities throughout France, and was the chief promoter of the Cité de Clairvivre—the French equivalent of Papworth. He was also the originator, as well as the chief administrator, of the Colonies de Placement Familiale des Tout-Petits—a system for the removal of the newborn child from its tuberculous mother to healthy surroundings. Léon Bernard was a member of the Permanent Committee of the Office International d'Hygiène Publique, secretary of the International Union Against Tuberculosis, and adviser to the League of Red Cross Societies, to whose successful birth he contributed not a little at the Cannes meeting in 1919. Though he was best known as a clinician and administrator, his qualities as a laboratory and research worker were rated so highly by the authorities that, at the time of Roux's death, there was serious talk of Léon Bernard being asked to succeed him as head of the Pasteur Institute.

New Street Accident Hospital in Paris

In the past a goodly proportion of the street and other local casualties found their way to the old Beauljon Hospital, in which President Doumer died after being shot on May 7th, 1932. The Beauljon is now to have a successor in a less central part of Paris, and its emergency activities will be taken over by a small new public hospital to be devoted exclusively to street accidents. There are to be only forty-seven beds for such cases, and the hospital will be given the name of Fondation Paul-Marmottan in commemoration of its principal benefactor. The building will be one of four stories, the first three being for the accommodation of the patients themselves and for a radiological service. On the fourth floor there will be accommodation for operating theatres and for services ancillary thereto.

England and Wales

The British Post-Graduate Hospital and Medical School

The new buildings at Hammersmith are rapidly approaching completion. A priced schedule of equipment for all purposes was prepared some time ago, the estimated expenditure therefor amounting to £52,800, exclusive of sterilizers and certain constructions which had to be obtained, at an estimated cost of £1,450, as the building works proceeded. The total estimated cost for works and equipment is £198,000. It is thought that it would be a very complicated and difficult matter to determine, in accordance with the terms of the agreement entered into last year between the London County Council and the Corporation of the School, what equipment is required for the use of the hospital separately, and for the use of the school separately, particularly as a certain amount of equipment will be used by the hospital and school jointly. The equipment for the purposes of the hospital, having regard to the post-graduate teaching which is to be given therein, is necessarily on a more extensive scale than would ordinarily be required at a Council hospital; on the other hand, the superior equipment of the school will be to the hospital's advantage. It is therefore proposed

that the cost of the whole of the initial equipment shall be divided equally between the two parties, as has been done in the case of the buildings. Various developments are taking place at Hammersmith Hospital in anticipation of the establishment of the school. When the block containing the new labour rooms is opened additional maternity beds will be required, and these are to be obtained by the adaptation of a ward in another block to provide for seventeen maternity cases. Accommodation will also be provided for twelve cots, with a bathing bay and sun balcony. Additional isolation accommodation will be necessary, to be obtained by the adaptation of a single-story block hitherto used for maternity purposes, with accommodation for a nursing staff of five. It is also proposed to fix glazed sliding sashes to the six sun balconies so as to provide adequate fresh air and protection from the weather. The hospital formerly had only one entrance, but a new entrance, with a roadway for all goods traffic, is being constructed at its western boundary. As already announced, it is intended to make provision for a radiological department at Hammersmith which shall be a consultative centre for the whole hospital service of the L.C.C. To this department cases will be sent from other hospitals for expert opinion on diagnosis and treatment. The officer in charge, whose salary will be £1,500 a year, will be designated "Director of the Radiological Department of Hammersmith Hospital and Consulting Radiologist to the Council's Hospitals."

Medical Society of London

The first half of the session 1934-5 of the Medical Society of London will open on Monday, October 8th, with the annual general meeting at 8 p.m., followed by Lord Horder's presidential address on "Medicine and Morals," at 8.30 p.m. On Monday, October 22nd, at 8.30 p.m., a discussion on the anaemias and their treatment will be introduced by Dr. Leslie Witts. A clinical evening will be held on Monday, November 12th, at 8 p.m. A discussion on the value of accessory methods in the diagnosis of intracranial tumours and allied conditions will be opened by Mr. Hugh Cairns on November 26th, at 8.30 p.m. On Monday, December 10th, at 8.30 p.m., Dr. H. Graham Hodgson will introduce a discussion on the future of diagnostic radiology. The Lettsomian Lectures will be delivered by Mr. J. E. H. Roberts on February 18th and 27th and March 4th, 1935, at 9 p.m. Sir William Willcox will deliver the annual oration on Monday, May 13th, 1935.

Residential Treatment of Tuberculosis

For many years the London County Council has published after-histories of patients who have received residential treatment for tuberculosis under its scheme. The latest particulars relate to the number of survivors of those who received treatment and were discharged in 1923. The number of adult patients discharged from institutional treatment during that year was 4,867, in 290 of whom the diagnosis of tuberculosis was not confirmed, and of the remaining cases the subsequent history of 437 cannot now be traced. Of 766 early cases 71.8 per cent. have been found to be alive after the five-year interval, of 2,149 moderately advanced cases 34.6 per cent. have been found to be alive, and of 960 advanced cases 4.7 per cent., while of 261 surgical cases 75.8 per cent. were surviving. During the same year (1923) the number of children discharged from residential institutions after having received at least one period of residential treatment was 938. In 171 cases the diagnosis of tuberculosis was not confirmed, and in eighty-six others reports were not available. Of 148 early pulmonary cases 12.2 per cent. were dead after five years, of thirty moderately advanced cases 63.3 per cent. were

dead, and of twenty-eight advanced cases all were dead. The proportion of deaths, after five years, in 475 surgical cases was 5.9 per cent. The London County Council is proposing no longer to require contributions towards the cost of the residential treatment of tuberculosis from patients or persons legally responsible for them. In the opinion of the Hospitals and Medical Services Committee the requirement is neither sound in principle nor desirable in practice. In fact, less than 30 per cent. of the cases treated have been so assessed, and the sums collected annually in recent years have been about £11,000, while the cost of collection has been £1,800. It is pointed out that it has been a principle in connexion with the assessments for tuberculosis in the past that regard should be paid to the importance, on medical grounds, of maintaining the standard of living of the family. Tuberculosis is a disease in dealing with which it is vitally essential that nothing should be done which might give cause for financial worry or anxiety to the patient or patient's family during treatment, or be likely to lower the resistance of the family to disease. It is, moreover, a disease specially liable to recur, and the heaviest mortality among tuberculosis patients occurs during the first four or five years after discharge from institutional treatment. It is very necessary that employment undertaken by ex-tuberculosis patients should be suitable, and that they should not be forced by financial circumstances to take unsuitable employment. It is added that there is no desire that the discontinuance of assessments should in any way affect the carrying out by Care Committees of their primary and important functions with regard to the tuberculous. The new Council appreciates greatly, as its predecessors did, the services rendered by voluntary workers on the Care Committees and by the officers of the borough councils associated with the work.

Coroners' Inquests in London

During 1933 the number of deaths reported to London coroners was 8,533, an increase of 173 on the figure for 1932. Of these 3,025 took place in mental hospitals and other institutions. The coroners held inquests in 3,543 cases and directed post-mortem examinations in 2,896 of these cases, as well as in 2,962 of the other cases in which no public inquiry was necessary. A verdict of murder was returned in seven cases and of manslaughter in two. The total number of suicides was 760, an increase of forty-one on the year. Three inquests were held in connexion with executions. Deaths from want of attention at birth decreased from forty to twenty-eight. The number of people who met their death by accident was 1,965, as compared with 1,892 in 1932. Injuries accounted for thirty-two deaths, and there were fifty-four deaths by drowning. A verdict of "Death from natural causes" was returned in 504 cases, and there were seven verdicts of "Cause of death unknown." Inquests on newly born children decreased from sixty-seven to forty-four, and verdicts of murder of the newly born were returned in only two cases. Excessive drinking accounted for fifty-three deaths, as compared with fifty-four a year ago.

Fire and Explosion Risks in Operating Theatres

The London County Council has asked the Minister of Health to consider the desirability of an investigation being made into fire and explosion risks in operating theatres due to the use of modern anaesthetics and electrical appliances, with a view to the formulation of effective safety precautions. Until such time as an authoritative decision on the matter is available, the practice of requiring that switchgear provided in registered nursing homes shall be of the highest standard commercially obtainable will be continued.

Salaries of District Medical Officers

Last year the London County Council fixed provisional salaries to be attached to certain positions of district medical officer, but statistics now available as to the work in the new medical relief districts show that in certain cases the provisional salaries are not commensurate with the amount of work the officers have to undertake. From October 1st next, and until the whole question of the district medical service is reviewed, the salary will be increased, in three districts by £35, in six by £50, in one by £75, and in one by £110.

Hull Royal Infirmary

During the past five years the work of the pathological department of the Hull Royal Infirmary has more than doubled, and in the annual report of this institution for 1933 it is announced that certain alterations and extensions have consequently had to be effected at a cost of over £850. The permanent appointment of an assistant pathologist is also recorded. The efficiency of the x-ray department has been increased by structural alterations and the provision of a new dark room. Other new staff appointments rendered necessary by the increase in the work of the Infirmary include that of a third honorary physician to relieve the strain imposed by the opening of the Sutton Branch, and of a resident surgical officer to co-ordinate this side of the work. There was an increase in the number of in-patients treated during the year under review, establishing a new high record for the Infirmary. As regards the associated activities, it is reported that a preliminary training school has been opened in order that probationer nurses may receive some preliminary instruction before taking up ward duties. This innovation has proved to be valuable to the institution as well as to the students. In order to help out-patients who would normally have to attend daily at the Infirmary for dressings, and for whom the journey would have been a hardship owing to distance or home conditions, the executive committee of the Hull Jubilee District Nursing Association made arrangements during 1933 for their nurses to attend such patients in their homes. In this connexion it may be noted that there was a marked decrease in the number of out-patients treated at the Infirmary in 1933 as compared with 1932, though the number of casualties treated increased. An arrangement has been made with the Hull Incorporated Law Society whereby patients admitted as the result of accidents, and who express a desire for legal advice, are put into touch with local solicitors on the society's rota. The service is not necessarily free, but where it is found, on investigation, that a patient is not able to pay for the legal aid required, the case is passed on to the Poor Man's Lawyer Committee of the Hull Community Council. The main object of the scheme is to prevent patients from getting into the hands of touts, and it is also hoped that where the Infirmary is legally entitled to payment for maintenance (as in certain cases under the Road and Rail Traffic Act) the new arrangement will be of value in securing a speedy and satisfactory settlement in this respect. Another arrangement with the Hull Community Council provides that the council's social service secretary shall act as part-time almoner in the case of patients needing after-care treatment and advice. A Samaritan fund has been brought into being for helping indigent patients who require such accessories as special appliances. In the year under review there was an excess of ordinary expenditure over ordinary income of nearly £7,000; not since 1928 has there been a year when ordinary income equalled expenditure, and the accumulated deficit since that time now amounts to more than £23,000. Several large special donations were received, however, during the year, and various voluntary committees have rendered generous help.

Scotland

Housing Amenities in Scotland

The Secretary of State for Scotland has set up an advisory committee to the Department of Health to consider how architectural quality and amenity may best be incorporated in the layout, planning, and external treatment of houses for the working classes in both town and country, and to consider whether higher tenements than have hitherto been accepted should be permitted. The chairman of the committee is Mr. J. R. Richmond, C.B.E., director of an engineering firm in Glasgow, and the members include a number of prominent Scottish architects and surveyors. It is hoped that the work will lead to improvement in the general amenity and quality of buildings to be erected, especially in places where clearances are to be made and where it is desirable to rehouse as many of the dispossessed dwellers as possible in sites near their work. It is proposed that new tenements shall follow the present Continental models, with balconies, gardens, and possibly roof-gardens. The new scheme is part of the Government's housing plan, under which it is estimated that some 200,000 houses are still required in Scotland.

New Scottish Hospitals

The Aberdeen Town Council has approved the erection of a special block in the new Aberdeen Royal Infirmary buildings, Foresterhill, for the treatment of diseases of the ear, nose, and throat at an estimated cost of £60,000, as part of the Joint Hospital Scheme, for which a sum of £400,000 was subscribed. The Public Health Committee of Dunfermline Town Council has recommended a site at St. Leonard's, on the south side of Dunfermline, for the erection of a new maternity home and hospital. The accommodation in the present hospital, which has been successfully managed by the Corporation for some years, has recently been found insufficient for the number of patients applying for admission. It was intimated at a meeting of Peterhead Town Council that a gift of £5,000 had been received from Mr. William Shewan to provide a hospital for the town. A condition of the gift was that within five years a suitable hospital should be established and equipped.

Pithead Baths in Fife

Pithead baths, which have been erected at a cost of £13,000, provided by the Miners' Welfare Committee, were opened at the Aitken Colliery, Kelty, on August 23rd, by Dr. T. G. Nasmyth, Edinburgh, senior director of the Fife Coal Company, to which the Aitken Colliery belongs. The baths are the second largest in Scotland, accommodating 912 men. Dr. Nasmyth said that the provision of pithead baths was one of the best sanitary reforms of recent years, and it was satisfactory that this matter was being dealt with all over the mining areas of the country.

Mr. J. B. Priestley and Mr. G. L. Stampa have collaborated in the preparation of an impressive foreword to an interesting little book issued by the Anti-Noise League of 18, Old Cavendish Street, London, W.1. Mr. Priestley, who confesses to having written the article while his ears were stuffed with cotton-wool in a vain attempt to secure a reasonable degree of silence, laments that "hardly anybody is busy inventing quietness." The book reveals that the Anti-Noise League, of which Lord Horder is chairman, has already accomplished a good deal of useful work during the ten months of its existence. It appears that the League was largely instrumental in securing the new Road Traffic Act provisions for silence zones in which hooting at night is prohibited and the placing upon manufacturers of the responsibility for fitting effective silencers to cars.

CORRESPONDENCE

Medical Education

Responsible Clinical Experience

SIR,—While a member of the Education Committee which has now reported to the Council and the Representative Body, I gave my support to what may be described as the main objective of the committee—namely, that the medical graduate should have the benefit of a period of responsible clinical experience before taking up the duties of public practice—I differed, however, from the majority of the committee as to the means of achieving this objective. As I was assured by the Chairman that an expression of individual opinion in the *Journal* would be considered by him a proper proceeding, even though it was at variance with the recommendations of the committee, and believing that the particular point of difference is an important one, I desire to put my alternative proposal on record.

The committee's recommendations achieve the end in view by:

1. Compressing the organized institutional tuition into a period of four years and three months.
2. Requiring the student, still a pupil and unlicensed to practise, to employ the remaining nine months of the five years' curriculum in some responsible clinical appointment.

My alternative proposition was:

1. To leave the period of organized institutional tuition unchanged (that is, five years), and to admit the student to the *Medical Register* at the end of this period.
2. To require from every so registered medical practitioner a period of one year in a responsible clinical appointment before a licence for independent public practice is granted to him. I proposed that this year should be spent either as a resident in hospital or as an assistant in general practice, or as both, according to the intentions of the individual practitioner.

The committee was influenced by two important considerations—that the curriculum should not be lengthened and that its expense should not be increased. Both requirements are met by both of these alternative propositions, but in my view my own alternative is the better in that:

1. It avoids the further compression of an already overburdened curriculum.
2. It avoids all the difficulties incident to the responsible and comprehensive employment in hospital or in general practice of an unregistered practitioner.
3. It ensures, in a simpler way, the two main requirements—adequate theoretical instruction and an adequate training in the public application of that instruction.

It is impossible to discuss details in a letter, and I must content myself with pointing out that the practitioner registered under the alternative scheme, but not independently licensed, would be worth a salary to a general practitioner or to a hospital sufficient to keep him, whereas the general practitioner and the hospital would have great difficulty in finding employment for a fifth-year student: the responsibilities which could be entrusted to him would be limited. Admitted that this difficulty might be evaded by an alteration in the "covering" regulations of the General Medical Council, but it is questionable whether the alterations which would be necessary are desirable.—I am, etc.,

London, W.1, Sept. 2nd.

K. W. MONSARRAT.

Occupational Therapy

SIR,—Before the correspondence with the above heading is closed I would like to add my testimony to the great value of wisely directed work for cases of mental illness, especially when this is selected and organized under medical control. To be wisely directed, it must not be pressed to the point of fatigue, it must have the concurrence of the patient, and it must not appear to be an attempt to secure an equivalent return for treatment. It must also be regarded as wholesome and beneficial exercise for the individual concerned.

At the recent annual meeting of the Royal Medical-Psychological Association in Northampton, several members—who were entitled by personal experience—spoke of the necessity of work in the interests of health, happiness, and the welfare of the patient; but there was a general feeling that the euphuistic terminology of "occupational therapy" was no new treatment in mental hospitals. The same paper was also read in London at the annual meeting of the Society for Promoting Mental Hygiene, which further demonstrates the importance of the subject. The physiological effect of occupation as exercise is evident in the quickening of the circulation, the aeration and purification of the blood in the expanding lungs, an improved appetite and digestion, and the general tranquillity of the patient through the refreshing sleep that follows. The psychological effects noted are a keener observation, a help to fix the attention—and therefore a distraction from delusional states—the correction of undesirable habits, the encouragement of self-control, and an increase in the skill of the worker. There can be great delight in muscular exercise and an added interest can be kindled in the production of others, whose good opinion is shown in return, and this acts as a further incentive to effort. Your recent contributor (Dr. A. J. Brock, August 25th, p. 375) adds other incentives to "occupational therapy"—namely, self-expression and the satisfaction of creative striving—which offer further inducements.

In my early experience at Claybury, the first asylum of the first L.C.C., opened in 1893, the patients were infused with as lively an interest as the staff in evolving order out of chaos: new roads were made; the grounds and drives were planted and the gardens laid out by the voluntary help of patients. Many scores of standard rose trees were budded by patients and flower borders arranged and afterwards tended with gratifying results upon the recovery rate. In the last years of my administration, during the war, the L.C.C. extended "occupational therapy" by undertaking the manufacturing, in the asylum workshops, of munition shells for artillery guns, under the direction of the late engineer (Mr. W. C. Clifford-Smith). Many hundreds of steel shells were turned out and taken to Woolwich to be charged with explosives for the front. This is, I believe, the first public statement that munitions were made in an asylum, and probably it is a unique record. Finally, I would like to add that the corridors and workrooms still bear evidence of the aesthetic decoration of the walls by "occupational therapy."—I am, etc.,

Plás Dinas, Carnarvon,
Aug. 28th.

ROBERT ARMSTRONG-JONES.

Is High Blood Pressure a Risk?

SIR,—With reference to your correspondent's letter of August 25th (p. 370) I give the following experiences. I was once asked to examine lives for a certain insurance company. On my first visit two young men presented themselves, and both had systolic blood pressures in the vicinity of 150 mm. Hg. The next day the manager of the office and his worthy benchman assured me that my examination was unsatisfactory, as the blood pressure

readings were too high and would preclude their acceptance.

I must say that I had been provided with a sphygmomanometer by the company, and I was expected, though I did not then know it, to use the stethoscope method. This I did not employ, reading the instrument, which was an aneroid, when the pulse could no longer be felt. The manager forthwith blamed my "wrong methods" for the wrong readings. After some unpleasant discussion I indicated that perhaps his sphygmomanometer was wrong, since it was an aneroid. He repudiated this suggestion on the grounds (1) that it was the best possible make, and (2) that it had been recommended by a certain consultant. Not being intimidated by either (1) or (2), I forthwith took the sphygmomanometer to a near-by instrument maker, where, with the aid of a "Y" connexion, I calibrated the aneroid against a mercury manometer. At about 150 mm. Hg the aneroid was exactly 11 mm. too high! Knowing the frequency with which aneroids are used and the trust with which physicians year in and year out use them for blood pressure readings, it is to be expected that many are badly out of calibration and their readings worthless.

In general practice I frequently come across cases of men and women (more often the latter) in whom the blood pressure has been very high for years and whose readings are more often in the neighbourhood of 300 than 200 systolic. I have one patient who has been in this state for the past seven years and is apparently none the worse. So much is this the case that I habitually tell a good and deliberate lie to patients as to what their pressures really are. Statistical investigations doubtless prove high blood pressures to be dangerous, but when it comes to a given patient there is no criterion whereby to judge the prognosis.

Average results are the bane of medicine and utterly useless to the individual, and as for insurance companies, anyone who has followed the trend of medicine for the last twenty years knows that, like the law, they are asinine.—I am, etc.,

Glasgow, Aug. 29th.

THOMAS ROBERTSON.

The Swab in Diphtheria Diagnosis

SIR,—May I direct attention to a method I have found convenient during the last twenty-five years. It was, I think, originally suggested by Hewlett. Assuming a visit late at night to a doubtful case, when one may not have an outfit for taking a swab at hand, a hard-boiled egg is almost always obtainable. This provides, in my experience, a reliable culture medium. An incubator is not essential; the inoculated egg may, for example, be kept near the hot-water cistern. The culture can be examined the following afternoon, and very valuable time saved.

It would be too much to expect the average practitioner of the present to make his own diagnosis in this way, but why should the average practitioner of the future not do so?—I am, etc.,

Manchester, Aug. 29th.

J. STAVELY DICK.

SIR,—With regard to the negative swab in cases of true diphtheria, perhaps an experience of mine in 1929 may be interesting.

I was called on August 5th to a case of nasal catarrh, and, being suspicious, took a swab: result, negative. A fortnight later I sent another with the same result. Four further cases, which had been in contact with the original, developed bad throats—swabs of all were negative. I injected all cases with 20,000 units of diphtheria antitoxin, and asked the county medical officer of health

to come and inspect, as I was certain they were cases of diphtheria. Both county medical officers came down and took swabs. Some were sent to London and some to Exeter: result, negative to diphtheria, but the pneumococcus was found. Not until October 29th did I get a swab positive to diphtheria. Two patients died in a few days, and the eldest sister died of complete paralysis.

It appears to me that the pneumococcus has an inhibiting effect on the growth of the Klebs-Loeffler bacillus, either *in situ* or on cultivation. When I have had a report of streptococcus I have never had diphtheritic symptoms develop.—I am, etc.,

Lynton, North Devon, Aug. 22nd. ARTHUR P. CUMMINGS.

SIR,—In view of recent correspondence on swabbing throats in diphtheria, my last three cases bearing on this question serve to illustrate the difficulties from the general practitioner's point of view.

1. A young labourer presented himself at surgery with some slough on right tonsil: Not ill in himself, but had been home two days. I labelled him septic throat, did not give serum, but swabbed him. Two days later throat was quite clear of slough, and I told him he could return to work. Five minutes after he had left surgery I received result of swab by 'phone—positive! As he had a family of young children I had no alternative but to send him to isolation hospital. Four days later he was discharged with two negative swabs and "not clinically diphtheria" (with which, of course, I could only agree).

2. Ten days later I was called in to one of his children, suffering from "clinical diphtheria." I isolated her at home, gave 24,000 units, and swabbed. On receipt of positive result I sent her to hospital two days later.

3. A young married woman, with what I considered typical clinical diphtheria: I sent her into hospital straightway. Seventeen days later she was discharged with the report, "Not diphtheria, but septic throat."

In theory, Nos. 1 and 3 should not have been sent to hospital, and No. 2 should have been admitted at once! Nevertheless No. 1 probably was a carrier, and possibly gave it to No. 2, who perhaps did not suffer much by delay in admission, as she got her serum immediately. Cases like No. 3 make one chary next time of sending a case straight into hospital.

It is quite obvious from the correspondence on this subject that I am not the only G.P. who could sign himself

August 28th.

PERPLEXED.

Typhus in the Tropics

SIR,—In the *Journal* of August 18th (p. 320) I notice a statement in the report of the discussion on typhus fevers in the Tropics which, if not amplified, may give rise to misunderstanding. Dr. J. L. Gilks is reported as having said that the first description of typhus in East Africa was given by himself in 1920. This is correct as far as it goes, but I am sure that Dr. Gilks does not mean it to be understood that he was the first to recognize that the disease, known for years in Nairobi as "dengue," was in reality mild typhus. The credit for this discovery belongs solely to Dr. G. V. Anderson, as I pointed out in a communication to the *Kenya Medical Journal* some years ago. The clinical and laboratory work which established Dr. Anderson's diagnosis was done by members of the Government Medical Service. The results were published by the Director of Medical and Sanitary Services, Dr. Gilks, in his annual report.—I am, etc.,

Belfast, Aug. 20th.

P. A. CLEARINK.

Rectal Prolapse Complicated by Procidentia

SIR,—The divergent views which have been expressed in the correspondence portion of your estimable *Journal* on the treatment of rectal prolapse is further proof that no universally successful operation has yet been evolved for the treatment of this most harassing condition. It seems to me that the ideal operation will only be evolved when our views on the aetiology of rectal prolapse are as well established as those on genital prolapse. The pre-eminent success of the Fothergill operation for the latter condition bears out the truth of my statement.

It is well known that rectal prolapse is common at the extremes of life and rare in adults. Beyond these known facts, the aetiology of rectal prolapse, as it occurs particularly in the adult, seems to be wrapped in mystery. Relaxation of the anal sphincter (and I include the levator ani muscles as part of the sphincter mechanism) may be a factor in the production of rectal prolapse, but, as we shall see, it is not the whole story. Jeannel and Verneul have called attention to the rarity of this condition after traumatism and destruction of the sphincter ani muscles, as, for example, after fistula in ano operations or in perineal lacerations. Stress is laid upon relaxation of the supporting structures of the rectum as an important aetiological factor but what precisely are these structures?

Some years ago I presented to the Obstetrical Section of the Royal Academy of Medicine in Ireland a case of complete prolapse of the rectum, complicated by procidentia. The partial cure obtained by surgical treatment in this case throws a certain amount of light on the aetiology and treatment of rectal prolapse. The patient was a nulliparous woman in the late forties. The first stage of the Fothergill operation for procidentia was carried out in the ordinary way. The second stage, which consists of a colpoperineorrhaphy, was slightly modified. The levator ani muscles, as well as being sutured to each other, were sutured also to the rectum. The external sphincter of the anus was exposed, as in the operation for complete perineal tear, and so complicated as to diminish the size of the anal orifice. The procidentia was permanently cured, and there was no recurrence of the rectal prolapse. A month or so afterwards, however, the patient developed a high rectocele. I had intended to perform a complete obliteration of the pouch of Douglas for the permanent cure of the rectocele, but the patient refused to have the operation. At present the rectocele is fairly well controlled by a ring pessary.

In order to appreciate the inferences which I think logically follow from this case it is necessary to understand the meaning and aetiology of a high rectocele. It is a protrusion of the rectum into the upper portion of the posterior vaginal wall and into the posterior fornix. It is due to the relaxation of the specialized portion of endopelvic fascia which maintains the rectum at its proper level in the pelvis. This consists on either side of a broad vertical band of dense fascia, which contains the middle haemorrhoidal artery, and which extends from the lateral aspect of the rectum to the pelvic wall at the point where the ureter enters the bladder. A high rectocele differs essentially from a low rectocele (the common type), which is a protrusion of the lower portion of the posterior vaginal wall, and which, on account of a mild inflammation of the cellular tissue plain, carries with it a portion of the anterior rectal wall. Should the sphincter ani be relaxed a high rectocele never develops.

In the light of the explanation of the significance of a high rectocele I believe I am entitled to draw the following conclusions from the results of my operation. That, in the adult at any rate, complete rectal prolapse, like a high rectocele, is essentially due to weakness, either congenital or acquired, of the true lateral supports of the rectum, and that weakness of the anal sphincter is a contributory factor. Rectal prolapse in the adult, therefore, is of the nature of sliding hernia. In the female, however, if the sphincteric mechanism of the anus is intact, a high rectocele may develop instead. If the view is accepted that relaxation of the sphincter ani is a contributory factor in the production of rectal prolapse in the adult, then an attempt should be made in the first instance to restore normal sphincteric control. In the female, then, the treatment for complete prolapse of moderate degree is a modified colpoperineorrhaphy. A few years ago a contributor

to the *Journal* reported three cases of complete rectal prolapse in the female successfully treated by this method. In the adult a somewhat similar operation may be carried out by making an anterior curved incision in the perineum and continuing the operation by an approach much like that for a perineal prostatectomy. Lockhart-Mumery's operation for a moderate degree of rectal prolapse is successful in a large number of cases. It is a most inelegant operation, however, requiring a considerable amount of post-operative care and confining the patient to bed for weeks. In an extreme degree of prolapse, or in the event of a recurrence of the prolapse in the male, or the development of a post-operative high rectocele in the female, then an operation for the complete obliteration of the pouch of Douglas (Moschowitz's operation) should be performed.

As visiting surgeon for many years to a large children's hospital in Dublin, I have had the opportunity of seeing and treating many cases of rectal prolapse in children. Mucosal or partial prolapse is observed particularly in children, and complete rectal prolapse, unlike that in adults, is invariably preceded by mucosal prolapse. When the latter condition persists for some time the anal sphincter becomes stretched and temporarily weakened, and so the partial prolapse becomes complete. The mechanism of production of complete prolapse in children is, then, essentially different from the rarer form which occurs in adults. In children, operation for prolapse is rarely indicated, because healing practically always occurs spontaneously, and the anal sphincter regains its tone when the aetiological factors responsible for mucosal prolapse, such as diarrhoea, hernia, etc., are removed. Occasionally the prolapse persists in spite of appropriate treatment for the removal of the causal factors. It is in such cases, and in the intractable cases of old age, that injection treatment finds its most fruitful application. Personally I have not tried this method of treatment in children.

I have found the simple rectopexy operation, so accurately described by a recent correspondent, almost invariably successful in the treatment of intractable rectal prolapse in children. That the injection of alcohol or any other drug into the perirectal tissue should permanently cure a case of complete prolapse in which the supporting structures of the rectum, as well as the sphincteric mechanism of the anus is permanently damaged, is too much for my credence.

—I am, etc.,

Menorrhagia after Splenectomy for Purpura Haemorrhagica

SIR,—Your readers may be unduly influenced by the success attending splenectomy for menorrhagia as recorded by Dr. Stanley Hartfall and Mr. Carlton Oldfield in your issue of July 7th (p. 8); with encouragement in a later issue by Dr. Bernard Myers (August 11th, p. 284). The purpose of this letter is to show the other side of this question.

Splenectomy for purpura haemorrhagica was introduced into this country by Dr. G. A. Sutherland, assisted by the writer, in 1924, with two cases recorded in the *Lancet* in February, 1925. Dr. Parkes Weber was our source of information on the origination of this treatment by Kaznelson of Prague in 1919. The post-operative histories of our original two cases, which were classical examples of the so-called essential thrombocytopenic purpura haemorrhagica, clearly show that splenectomy is certainly not the solution of the problem.

During a post-operative period of ten years one of these patients, a female, has had many serious haemorrhages, and at the onset of her menses five years after splenectomy menorrhagia reduced the numbers of red cells below two millions, and she lay in hospital for many weeks. For a period of eighteen months following the operation all signs of purpura haemorrhagica disappeared. After this they gradually returned, and her constant state now is one of purpura simplex—that is, petechiae and ecchymoses are seldom absent—but, in addition, she has occasional epistaxes. The third patient whose case

was reported in our original article, and who was later subjected to splenectomy, is in the same condition as the case just described: she has skin manifestations of the condition as a constant feature, occasional external haemorrhages, and a definite tendency to menorrhagia.

Splenectomy has established itself beyond doubt as an emergency measure in purpura haemorrhagica. In my experience, apart from such a state of emergency, it has been completely disappointing. Our original cases at the present time can be diagnosed clinically at sight, and the blood state shows a constant thrombocytopenia despite the removal of the spleen. This has been recorded by others. The spleen is only one unit in the reticulo-endothelial system, and if this system is the primary fault the rest of the system appears to be able to ensure the continuance of the disease.

Experience has modified my views during the past ten years. I now look upon purpura haemorrhagica as a manifestation of obscure infection in which the capillaries are especially prone to attack. The platelets disappear from the circulation because these are employed in caulking the damaged vessels. Measures to raise the general standard of health by eradicating sepsis, combating anaemia, and attending to the diet have brought me more permanent results, and I now reserve splenectomy for cases of utmost emergency where haemorrhages endanger life.—I am, etc.,

London, W.1, August 22rd.

BRUCE WILLIAMSON.

Treatment of Phlebitis

SIR,—Thrombosis and subsequent phlebitis of the saphenous vein and its tributaries is very common, especially among females, and causes considerable loss of working time. Treatment has always been most disappointing. Some patients, unable to bear the pain, seek their beds, and lie there for months courting pulmonary embolism through clotting of the internal iliac veins; others walk about and appear to do as well as, if not better than, the recumbent cases. The exhibition of massive doses of potassium citrate has been recommended, but it is difficult to understand how this substance taken by mouth can affect a clot, still less have any effect on the inflammation.

Mr. Dickson Wright's treatment of encasing the whole leg from the toes upwards is the only one I have known to be of any avail. I have used it in two cases since reading his article. One had been under treatment for months, the other was a recent one of clotting only; both patients had varicose veins. As a modification I used animal wool over the areas of thrombosis. This wool shows no tendency to mat and is very elastic, for which reasons it is used by chiropodists. The result in both cases was most gratifying.—I am, etc.,

A. P. BERTWISTLE, F.R.C.S.Ed.

London, W.1, Aug. 23rd.

Thrombosis of the Penis

SIR,—I am very glad to see Mr. Clifford Morson's extremely clear explanation of the difference between the terms "priapism" and "pseudo-priapism" (*Journal*, August 25th, p. 371), though it makes the title of a paper which I wrote long ago ("Persistent Priapism from Thrombosis of the Corpora Cavernosa," *Edinburgh Med. Journal*, new series, 1898, iv, p. 267) contain a contradiction in terms. With the progress of knowledge the definition of terms has, I admit, not rarely to be modified or altered, especially for teaching purposes, and Mr. Morson's definition is certainly more intelligible to me than Dr. G. W. Theobald's statement (*Lancet*, 1922, ii, p. 506): "Priapism is not synonymous with 'prolonged erection' or with satyriasis, but is a condition in which

the penis is erected without there being any associated sexual excitement."

I must apologize for having at first doubted the advisability or necessity of Mr. Morson's use of the term "pseudo-priapism," but doubt, just as hope, springs eternal in many human breasts, and now I find myself doubting whether Priapus himself—standing day and night through all kinds of weather in the fields and groves of the ancient classical world, always exhibiting his enormous and erect phallus—may not have been, after all, a sufferer from some kind of vascular pseudo-priapism.

I am sorry that I have no information to give Mr. Morson as to subsequent history of impotence, etc., in the few leukaemic and non-leukaemic cases of penile thrombosis which I have seen.—I am, etc.,

London, W., Aug. 25th.

F. PARKES WEBER.

"Closed" Anaesthesia

SIR,—I am struck by the following passage in your leading article on the above subject (August 25th, p. 360):

"The author notes that 'relative overdosage'—a phenomenon long familiar to anaesthetists—which means, in a sentence, that a given saturation of the blood by anaesthetic agent produces a deeper level of anaesthesia in the later than in the earlier stages of an administration, occurs much more noticeably in nervous than in stolid patients . . . that in the latter type a larger proportion of the drug used is absorbed into the blood."

It is then suggested that this is due to some physical difference in the blood of these different types of patients. This appears to conflict so much with clinical experience and with the theoretical evidence of such men as Crile and Henderson that I venture to disagree with this last statement, and for the following reasons.

In a closed system of anaesthesia once the level of anaesthesia has been reached which is desired clinically the supply of anaesthetic agents is stopped, and with an airtight system the anaesthetic content is from this time on a constant fixed amount. The contents of the system are in gaseous equilibrium with that of alveolar air, which is in turn an accurate measure of the gas pressure to which blood leaving the lungs is saturated. Thus, for this level of anaesthesia the anaesthetic content of the blood will be in equilibrium with the contents of the closed system, which is a constant fixed amount. In these circumstances it follows that when this relative tolerance does appear it cannot be due to an increase in the anaesthetic content of the blood, for until more anaesthetic agent is added to the system the anaesthetic content of the blood cannot rise, as it is in gaseous equilibrium with the contents of the system. Since in closed anaesthesia the control which one has over the anaesthetic agents used is absolute, one can vouch for the degree of blood saturation and its maintenance once the level of anaesthesia desired clinically has been attained.

If alterations occur in the patient's clinical condition these alterations must therefore be due to an altered reaction on his part—an increased susceptibility to that quantity of anaesthetic agent already present. In the nervous or the toxic patient this relative tolerance occurs earlier and more readily, and one must take it that his psychic or toxic state predisposes to the earlier onset of this phenomenon. Clinically one has come to look upon this phenomenon as a sign of incipient surgical shock. Crile's definition of shock is "a state of exhaustion which has been rapidly developed by psychic, traumatic, toxic, or thermal stimuli." His researches denoted that the psychic factor incident to major operations was exceedingly important: it was sufficiently powerful to overwhelm the patient, so that in some cases death was due to the emotional factor alone. I have seen just such a case.

If a basal anaesthetic is employed the nervous patient comes to the theatre freed from the influences of the higher cerebral centres. He is in effect a standard physiological preparation, in much the same manner as a decerebrate animal, and will consequently react in a standard physiological manner to a given set of conditions brought about by the anaesthetist. Patients so prepared do not so readily show signs of relative tolerance, but react after the manner of the stolid type. In closed anaesthesia a relative tolerance can develop apart from this toxic or nervous type. I believe this to be due to a too complete absorption of carbon dioxide by the soda lime, which lowers the carbon dioxide tension of the blood. This depresses the respiratory centre and reduces the amplitude of respiratory movement which, by preventing the relaxation of the heart in diastole, hinders the venous return and makes a circulatory failure possible as a result of the diminished cardiac output. Of equal importance is the production of an anoxaemia of the anoxic type. In spite of the fact that the oxygen tension in the blood is adequate, oxygen is not readily available owing to the low carbon dioxide tension hampering the dissociation of oxyhaemoglobin. By increasing the carbon dioxide contents of the system this clinical condition is rapidly rectified. If these causes have been allowed to act for too great a length of time the oxygen supply must also be increased. In event of an increase of carbon dioxide and oxygen failing to rectify the clinical condition of relative tolerance, the inference is that the causes have been acting for too great a length of time, and consequently the damage has been done and surgical shock is actively present. In this state the condition of relative tolerance or susceptibility—I would prefer to call it shock—has been established, and a reduction of the pressure of the anaesthetic agent in the system is necessary to reduce the tension of anaesthetic in the blood. At the same time the routine treatment of shock is instituted.

In a closed method of anaesthesia one can recognize clinically a "pre-relative tolerance" stage, a relative tolerance stage, and, finally, the stage of established surgical shock. The pre-relative tolerance stage is manifested by irregularities in, or shallowness of, the amplitude of respiratory excursions as shown on the manometer. The use of the carbon dioxide by-pass valve will rapidly rectify matters. In the relative tolerance stage, again, there are irregularities of respiratory movement, depressed breathing, and inspiratory tugging. The blood pressure falls, the pulse becomes full and soft, and may become rapid. These two stages are "pre-shock" stages, and are relieved by the exhibition of carbon dioxide, or carbon dioxide and oxygen. Shock is not established, and consequently, if those forces acting to produce it are relieved, its advance is arrested. This becomes a therapeutic test, for if the condition is not arrested then one can be perfectly sure the patient has reached the third stage—the state of surgical shock.

These facts lead one to consider that relative tolerance or overdosage is not due to any physical peculiarities of the blood *per se*, but rather to an increased tolerance—in effect, the early onset of shock. Its incidence can be reduced by the use of basal anaesthetics. In a closed system of anaesthesia it offers a reliable clinical index of approaching surgical shock. The physiological regulation of that hormone of the respiratory system, carbon dioxide, which in a closed system can be accurately controlled, will reduce the incidence of surgical shock, delay its onset, and provide a reliable guide as to whether it is actually established. A survey of surgical shock in anaesthesia and the relative value of different agents and methods is being investigated at present, and will be the subject of a future communication.—I am, etc.,

London, W.6., Aug. 29th.

T. A. B. HARRIS.

Treatment of Lupus Vulgaris

SIR,—Dr. Burnell-Jones is evidently of opinion that, however extensive the trials of tuberculin in lupus may have been in the past, they have not been adequate, and that the clinical work now in progress in London and elsewhere is likely to remedy the defect. I agree entirely with him on both points.

The London work to which he refers is described in a paper by Dr. H. Semon and himself entitled "Tuberculin in the Treatment of Cutaneous Tuberculosis," and published in the *Proceedings of the Royal Society of Medicine* (January, 1934). In this the authors describe cases of lupus showing definite improvement under progressively increasing doses of tuberculin B.E., rising to large quantities. If this work, on visible cases where we can see what is happening, is steadily continued for a sufficient length of time, we shall at last obtain material from which to learn the truth about the value of tuberculin, not only in lupus, but eventually in other forms of tuberculosis as well. Lack of the Hunterian method, carried out with intimate knowledge of Koch's work, has been to a large extent responsible for the inadequacy of the investigations into this subject in the past.

An article by Sir Malcolm Morris and Dr. Arthur Whitfield, entitled "Six Cases of Lupus Vulgaris Treated by Koch's New Tuberculin" (*British Medical Journal*, 1897, ii, 207), is almost the only serious attempt reported in this country to confirm, in lupus Koch's completed work on tuberculin. This article still merits close attention, but the work was too soon abandoned, owing apparently to the introduction of Finsen light treatment, or to being diverted by the opsonic index and fear of dangerous consequences—strangely enough after the authors had reported "full confirmation of the good effects referred to by Koch" and remarkable improvement in the cases treated.

It is greatly to be hoped that the work now in progress in London will not be hampered by want of support. Those who have worked at this problem know how heavy are the demands it makes on time, energy, and staying power. There are sufficient funds in the hands of the Medical Research Council and other bodies entrusted with the patronage of medical research to subsidize work of such potential practical value. I have no hesitation in calling upon all who are in sympathy with these views to unite in creating the demand for support of every description for one of the most promising, long overdue, medical researches of our time.—I am, etc.,

London, S.W., Aug. 26th.

ROBERT CARSWELL.

SIR,—In a letter from Dr. H. S. Burnell-Jones, published in the *Journal* of August 25th (p. 375), he declares that "it is wrong and unscientific to condemn tuberculin without an adequate trial. The endeavour should be made to learn how to use it."

It is pertinent to inquire on what grounds Dr. Burnell-Jones charges the medical profession with not having given tuberculin an adequate trial. Tuberculin has now been before the profession for some forty years. Having been widely given up after its first rather disastrous start, it was re-boomed about 1911. For some years it was tried on a most extensive scale, so much so that letters appeared in the *Journal* expressing a fear of tuberculosis dispensaries becoming "tuberculin dispensaries." Possibly these events do not fall within the memory of Dr. Burnell-Jones.

Further, he quotes Dr. Lomholt as saying—with regard to the use of tuberculin in lupus vulgaris—that it "had been tried extensively at the Finsen Institute," so we are left to infer that he does not consider this extensive trial at the Finsen Institute to have been an "adequate

trial," because the result was that tuberculin had been abandoned. Dr. Burnell-Jones thinks that we never learnt how to use it. Perhaps he will be kind enough to explain how our methods were all wrong, and what is the proper method as known to him.

We agree that "it is wrong and unscientific to condemn tuberculin without an adequate trial," but we deny the impeachment (which is surely just a little presumptuous on the part of Dr. Burnell-Jones), and we would point out that it is equally wrong and unscientific to credit tuberculin with the cure of tuberculosis on the strength of occasional good results in a disease which, as common experience shows, provides many instances of improvement or arrest of disease by the *vis medicatrix naturae* alone. He must produce satisfying evidence, supported by proper controls. Also, to talk of "widely different actions [of tuberculin] in different individuals" is simply to hedge. Not so do we speak of those specific remedies which have proved to be trustworthy in other diseases.—I am, etc.,

E. WEATHERHEAD.

Southborough, Tunbridge Wells, Aug. 26th.

Haemorrhage from Peritonsillar Abscess

SIR,—Both Professor J. B. Dawson (August 11th, p. 284) and Mr. Charles MacAuley (August 25th, p. 371) consider it wiser to tie the external, rather than the common, carotid in cases of haemorrhage from a peritonsillar abscess. I would remind them, however, that the tonsil is partly supplied by the descending palatine branch of the internal carotid (Cunningham). Should the bleeding originate from this source, ligation of the external carotid alone would certainly not "meet the case." Ligation of the external carotid will undoubtedly stop the majority of haemorrhages from the peritonsillar region, but the exceptions will most likely prove fatal. Any considerable further haemorrhage would certainly have killed my patient, and this fact was kept in mind when deciding which artery should be tied. Perhaps the best procedure would be to ligature the external carotid, and at the same time to leave a stout catgut ligature loosely around the internal carotid, ready to be tied at a moment's notice. Alternatively one could dissect out the tonsil and look for the bleeding vessel in its bed, as has been already suggested.

Both Professor Dawson and Mr. MacAuley comment upon the operative difficulty caused by swollen lymph glands. This was not present in my case, presumably because of the long interval which had elapsed between the bursting of the quinsy and the ligation of the artery.—I am, etc.,

Dublin, Aug. 27th.

T. G. WILSON.

Use of "Oil" Vaccine in Rheumatism

SIR,—In the *Journal* of August 25th Drs. Walsh and Frazer (p. 374) ask the size of the globules in the dispersed phase of the "oil" vaccine described in my letter (*Journal*, August 4th), stating that in their experience globules of a size of 2 to $2\frac{1}{2}\mu$ are too large to be of any value (2 to $2\frac{1}{2}\mu$, as their letter states, is no doubt a misprint— 2μ would, of course, be much too small to measure).

In our oil the average size of the particles is 1μ , gum acacia is used for protection, and the emulsion is rendered isotonic with mannite. The oil is sterilized by heat and preserved by 0.3 per cent. tricresol; 1 c.cm. of vaccine in carbol saline is then added to 9 c.cm. oil emulsion at 37°C . After an hour or two it is allowed to cool. We have found that the addition of the protective to the emulsion prior to the adsorption of vaccine is in no way detrimental, and the isotonicity obviates any local reaction at the site of injection. This, then, is the general "oil"

vaccine which the staff of the Charterhouse Rheumatism Clinic has now used in a considerable number of cases.

Experimental work is proceeding under Dr. Harry Coke's direction in order to determine: (1) a clinical elution isotherm in relation to the size of the particles and the relative surface available (at the other end of the scale we are therefore using a 50 per cent. protected isotonic emulsion of olive oil in which the average size of the particles is the same and the available surface very large); and (2) the effect of the chemical constitution of the dispersed phase. Here an attempt is being made to determine the relative value of other colloids in producing specific immunity and desensitization phenomena. We are trying colloidal cholesterol, calcium, and magnesium oleate (with an average size 0.1μ), calcium and magnesium phosphates and hydroxides, and, perhaps most important of all, the selective adsorption of calcium or magnesium salts with vaccine on a neutral colloid, such as silica. The preparations, as before, are by British Colloids, Ltd.

I should add that no means are taken for solution of the bacterial content of the vaccines. Partial autolysis is always to be found in vaccines prepared from broth cultures and put up in carbolized saline.—I am, etc.,

London, W.1, Aug. 30th.

H. WARREN CROWE.

"Port Sanitation and Common Sense"

SIR,—The article, so ably written by "A Ship Surgeon," in the *Journal* of August 25th raises many points of interest and calls for some comment.

His remarks anent "bills of health" are sound and true, but it is worth emphasizing that the reason for their loss of value is due to two things. First, news nowadays travels faster than the ship, hence the bill of health is out of date and valueless by the time a vessel reaches any port a reasonable distance from the port of origin. Secondly, thanks to the work of the International Bureau of Hygiene at Geneva, a weekly confidential list of all ports where infection exists, together with facts and figures, is circulated to all port medical officers, who are thus kept strictly up to date in information. With regard to British bills of health they are at least issued free, and not like some foreign ones where fabulous sums have to be paid for a piece of paper the philatelic interest of which far exceeds any potential or actual value. In the second part of your correspondent's paper, under the heading "Ship Hygiene," I think his outlook and picture are drawn from the interior of a first-class liner. Has he inspected many cargo vessels and smaller fry of the "tramp" class?

It is in the last part of his article, in which he criticizes port authorities, that I would cross swords with "Ship Surgeon." Abroad things may be out of date—in many cases I know they are. In Great Britain the port authorities have a very definite reason for every measure they take, and I cannot recall, or think off-hand of, a single matter which could be reasonably cavilled at. I agree that the status of the ship surgeon has improved, and in the larger companies, where something approaching a permanent career is offered, the best type of doctor is obtained. Port authorities have to consider all types, however, both British and foreign, and one cannot make one routine for the one and a different routine for the other.

The question, "Have you had any illness on board, whether of an infectious nature or not?" is most important, as "Ship Surgeon" promptly proceeds to substantiate in his succeeding remarks. Port medical officers have both the time and the patience to listen to a recital of the bo'sun's lumbago, the carpenter's rheumatism, and the steward's diarrhoea; for there at once lie the potential

and perhaps ambulatory cases of small-pox, gonorrhoeal sequelae, and typhoid fever, to name a few. The mere mention of the diagnoses "Ship Surgeon" gave would at once excite in the mind of a port medical officer such possibilities, and *quite possibly* would not have aroused suspicion in the mind of the ship's surgeon. Having been "let down" by each of these three types of case, I can speak with feeling on that point. I feel that I should personally treat "Ship Surgeon" with some suspicion if he declined to answer that question properly.

Surely he has taken the parochial outlook rather than the broad view with regard to port authorities. Does he not realize that they are out to help and not to hinder? The port medical officer, even abroad as well as at home, has special qualifications for knowing the major infectious diseases when he sees them, and in most instances meets them so frequently that he has the practice as well as the knowledge. Let the ship's surgeon therefore avail himself of a second and expert opinion whenever he can, lest one day he trip up over the differential diagnosis between his pimples and his small-pox. The port medical officer knows the local facilities for dealing with "the commander's indigestion" and "the stewardess's debility," not to mention "the fireman's whitlow," etc., and if assistance in landing and catering for these cases is required the port authority will help in the matter.

In short, the port authority does its best to take all the responsibility possible off the hands of the ship's surgeon, and it is up to him "to deliver the goods." In conclusion, let "Ship Surgeon" remember that most port medical officers know his difficulties, and most of them have been through them in the past; but whereas his charge is the relatively small "parish" of the ship the port medical officer's "parish" is the entire population of the country whom it is his duty to protect from imported disease.—I am, etc.,

August 26th.

"A PORT MEDICAL OFFICER."

Pineapple Juice in Oedema

SIR,—I should like to add another old-fashioned remedy to Dr. F. C. Bottomley's list for the treatment of oedema (as reported in the proceedings of the Section of Medicine, *Journal*, August 18th, p. 315). At Broken Hill (Australia) in 1929 I saw a case of cardiac oedema in a woman of 30 with a patent ductus arteriosus completely relieved in three weeks by the daily administration of pineapple juice. When the treatment was started the patient was oedematous to the waist, and there was fluid in both pleural cavities. Digitalis, mercurial compounds, and so on had been tried without success, and the pleural sacs had been drained and were filling up again rapidly. She was given the juice from a tin of pineapple daily, and in a fortnight her urinary output had risen from 18–20 oz. to 60–100 oz. in twenty-four hours. The oedema of her back and legs completely subsided and the fluid disappeared from the pleural cavities in about three weeks. The patient left the hospital, reporting some months later still apparently free from oedema: she was then consuming one tin of pineapple per week. The pineapple juice was administered in the first place because I was told that it was a good old-fashioned remedy for reducing the swelling of sore throats and quinsies, and nothing seemed to be doing the patient any good. The action of the juice may have been due to some essential constituent of the pineapple or to its sugar content, but this point has not been investigated. The case was fully reported in the *Medical Journal of Australia* in 1930.—I am, etc.,

BRIAN MAEGRAITH.

Sir William Dunn School of Pathology,
University of Oxford, Aug. 21st.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

During the months of June and July the title of the degree of B.Chir. was conferred by diploma upon C. M. Cavell and D. J. Thompson (Newnham College), and R. A. Kellgren (Girton College).

Charles Montague Fletcher, B.A. (Trinity College), has been elected to the Michael Foster Research Studentship.

The General Board gives notice that the composition fee for all medical students and for other students reading for the Natural Sciences Tripos, Part I or Part II, or for the Preliminary Examination in Natural Science, will be as follows: For undergraduates in their first, second, or third year an annual composition fee of £45, payable in three equal terminal instalments of £15; for students in their fourth year a terminal fee of £8.

The *Cambridge University Reporter* of August 14th included a list of lectures and courses of practical instruction in medicine, surgery, pharmacology, therapeutics, and pathology, and for the Diploma in Medical Radiology and Electrolgy, approved by the Board of the Faculty of Medicine for the academic year 1934–5.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—F. A. Frank, F. M. Kerry, J. T. Moohalaparakel.
MEDICINE.—S. Adams, T. D. R. Aubrey, M. T. Curran, A. H. El. S. El Mahallawy, R. C. H. Ensor, F. A. Frank, W. H. Jervis, C. W. O'Donoghue, J. F. Owen, H. Paroulakis, D. Walton.

FORENSIC MEDICINE.—F. G. S. Alderson, F. A. Frank, W. H. Jervis.

MIDWIFERY.—J. A. Amor, N. A. Bicchieri, D. P. Hickey, F. M. Kerry, K. P. Pauli.

The diploma of the Society has been granted to F. G. S. Alderson, M. T. Curran, J. T. Moohalaparakel, C. W. O'Donoghue, J. F. Owen, and H. Paroulakis.

The Services

AWARDS

The Gilbert Blane gold medal for this year has been awarded to Surgeon Lieutenant-Commander T. C. H. Neil, M.B., Ch.B., who obtained the highest aggregate marks at the examination for the rank of Surgeon Commander.

The King has conferred the Efficiency Decoration of the Territorial Army upon Lieut.-Colonel C. H. Budd, M.C., and Major V. H. Wardle, M.C., R.A.M.C.(T.A.).

DEATHS IN THE SERVICES

Lieutenant-Colonel Edmund Hasell Wright, Madras Medical Service (ret.), died at Woking on August 13th, aged 65. He was born at Masuri on September 16th, 1863, the son of George Augustus Wright, indigo planter, and was educated at St. Thomas's, taking the M.R.C.S., L.R.C.P. in 1887. Entering the I.M.S. as surgeon on March 31st, 1890, he became lieutenant-colonel after twenty years' service, and retired on November 8th, 1921. After fifteen years' military duty he was appointed civil surgeon and superintendent of the medical school at Tanjore in 1906, and civil surgeon of Merkara, Coorg, in 1916.

Major James Lafayette Lauder, D.S.O., M.C., R.A.M.C. (ret.), died on July 18th, aged 45. He was born on June 18th, 1889, the son of J. S. Lauder, Esq., and was educated at Dulwich and at Guy's, and took the M.R.C.S., L.R.C.P. Lond. in 1913, and the M.R.C.P. Ed. in 1916. He took a temporary commission in the R.A.M.C. on August 8th, 1914, was confirmed as lieutenant and temporary captain on January 1st, 1917, became captain on February 8th, 1918, and major on August 8th, 1926. He went on temporary half-pay on account of ill-health on August 17th, 1932, and retired two weeks later, on August 31st, 1932. He served throughout the war of 1914–18, was mentioned in dispatches in the *London Gazette* of December 11th, 1916, and December 24th, 1917, and received the D.S.O. and the Military Cross, the former for his services during the typhus epidemic of 1916 in the Wittenberg prisoners' camp.

Obituary

ROBERT ALEXANDER GIBBONS, M.D.,
F.R.C.P.Lond., F.R.C.S.Ed.

Consulting Gynaecologist to the Grosvenor Hospital for Women

We regret to record the death in London, on August 23rd, of Dr. R. A. Gibbons, the well-known gynaecologist. Born in Canada, he studied medicine at Edinburgh, graduating M.B., C.M. in 1874, and M.D. in 1877. Five years later he took the F.R.C.S.Ed. and the M.R.C.P.Lond.; he was elected F.R.C.P. in 1932. Dr. Gibbons held resident appointments at the Royal Infirmary, Edinburgh, and was for two years R.M.O. at the East Suffolk and Ipswich Hospital. He later obtained the post of resident medical officer to the Great Ormond Street Hospital for Children. Settling in a house in Cadogan Place in the 'nineties, he soon built up a

large and fashionable practice, and it was not long before he became known to a wide and important circle in London. He held the appointments of obstetric physician to the St. George's and St. James's Dispensary and the Royal Pimlico Dispensary, but it is in connexion with the Grosvenor Hospital for Women, Vincent Square, that Dr. Gibbons is best known. He was the founder of this hospital, which began in a very small way in two houses in the Square, and it was

owing largely to his energy and enthusiasm that the present well-equipped hospital was built. He collected considerable donations for it from his rich and grateful patients, and the hospital is, in truth, his child. He spent a large portion of his life doing excellent work there, and at his death was the senior consulting gynaecologist. Dr. Gibbons contributed a number of papers to medical journals and also the articles on dysmenorrhoea, sterility, and dyspareunia in Latham and English's *System of Treatment*. He also wrote two brochures on sterility in women and another on the causation of labour, a subject in which he was greatly interested and to which he devoted much thought, industry, research, and experiment. He had been a member of the British Medical Association for nearly sixty years, and was vice-president of the Section of Obstetrics and Gynaecology at the Belfast meeting in 1909.

Sir JAMES DUNDAS-GRANT writes:

The death of Dr. R. A. Gibbons will be a blow to a large circle of patients, friends, and fellow practitioners. For his patients it will be difficult to find an adviser who, in addition to having good judgement and skill, possesses in so high a degree his qualities of tact, delicacy, and sympathy, which are particularly indispensable in one who devotes himself to the obstetrical and gynaecological department of medicine. His personality, brightness, and loyalty endeared him to many friends, lay and professional. One who was a few years his junior when he was house-surgeon and house-physician at Edinburgh well remembers the example he set of business-like intensity in his devotion to work, and the consistent maintenance of the dignity of his calling in his conduct and bearing, even down to his preciseness in dress. The demand in London for his services as an obstetrician was so great that he decided not to accept the post of

obstetric physician to a teaching hospital, as he felt unable to devote to it the amount of time that would have been required for the conscientious performance of the duties as he conceived them. Among those who will deplore his loss will be the members of the Order of St. John of Jerusalem, in which he held the position of Knight of Grace, and many freemasons of all ranks. Up to the last he enjoyed his round of golf and maintained his appearance of youthful freshness, to which moderation in diet and regimen no doubt contributed. He took the serious things of life with seriousness, the lighter ones with good humour, and in more ways than one he was an ornament to his profession.

Sir GOULD MAY writes:

From the very beginning Gibbons's success in practice was phenomenal. Having studied under Lister in Edinburgh, he fully realized the importance of antiseptics, and he may be said to have been one of the pioneers of aseptic midwifery in London. A man of fine presence, courteous manners, and most generous instincts, he was always anxious and willing to help the younger man, while he was never puffed up by his wonderful success. Few doctors have been more beloved by their patients, and he will have the only monument worth having—a safe place in the hearts of all those who knew and loved him.

CECIL W. HUTT, M.D., M.R.C.P., D.P.H.

Medical Officer of Health for Holborn

The sudden death of Dr. Cecil W. Hutt, medical officer of health for the Borough of Holborn, at the comparatively early age of 54, removes a public official of undoubted distinction.

He was a Londoner by birth, and while at St. Paul's School he showed those gifts of scholarship which remained with him throughout his life. In 1898 he gained an exhibition to Trinity College, Cambridge, taking his B.A. in 1902 with a first class in the Natural Sciences Tripos, Part II. Then followed his medical training at St. Bartholomew's Hospital, where he was awarded the Matthews Duncan Prize and Brackenbury medical scholarship, qualifying in 1905.

After holding several clinical appointments he took the Oxford D.P.H., entering on his public career as assistant M.O.H. in Warrington, and later as deputy to Dr. Duncan Forbes, medical officer of health for Brighton, with whom he remained on the most intimate terms of affectionate friendship. He always looked back on the years at Brighton as the time of happy apprenticeship, and remembered with gratitude the valuable and varied experience he acquired there. There was much to do in Brighton during the war, for in that city was established the chief hospital organization for the Indian contingents, and the incidence among them of infectious disease, such as cerebro-spinal fever, gave much anxiety to civilian health officers there as elsewhere. As soon as he could be released Hutt joined the Army, and after a period of service in home commands was drafted to Egypt, where he had the misfortune to contract dysentery in a severe form. There is little doubt that the after-effects of this infection remained, and played a part later in undermining a constitution normally robust.

Soon after the war he was appointed medical officer of health for Dudley, and later for Richmond, Surrey, but it was not until 1921 that he succeeded the late Dr. Bond as medical officer of health for Holborn. A metropolitan borough does not offer so wide a field for an official of imagination and initiative as an area of comparable size in the provinces, but Dr. Hutt soon set the seal of energy and progress on the health services of the borough.

He found most scope in the newly developing maternity and child welfare movement, and to-day it would be difficult to find anywhere a more complete or better-organized service. He was the first medical officer of health in London to grasp the value of protective immunization against diphtheria, and his scheme for the general population was probably the first in operation in England. He was a Fellow and member of the Council of the Royal Institute of Public Health, Fellow of the Society of Medical Officers of Health, one of the founders of the School Medical Service Group, and took a prominent and executive part in the activities of the National Baby Week Council and the National League of Health Maternity and Child Welfare. Further, he occupied a position of considerable responsibility as the medical member among the advisory experts attached to the special subcommittee of the Metropolitan Standing Joint Committee which is dealing with the urgently important question of refuse disposal in London.

Hutt was a lucid and facile writer, and throughout his public career contributed very frequently to the medical and health journals on a variety of subjects dealing with public health. Among these may be mentioned "The Urgent Need of Reform of the Sale of Food and Drugs Act Administration (Public Health)" and "Diphtheria Immunization in a Metropolitan Borough (*Lancet*, 1925). School hygiene was the subject of his special interest, and he wrote a number of articles embodying much original thought both in French and in English journals. He was the author and part author of a number of textbooks, perhaps the earliest and best known being his *Hygiene for Health Visitors, School Nurses, and Social Workers*—one of the best books of its kind ever published. He collaborated with several others in bringing out a later edition of that excellent textbook, Sir William Hamer's *Manual of Hygiene*, and at the time of his death had almost ready for publication a more ambitious work on preventive medicine under the co-editorship of Dr. Hyslop Thomson. Travel abroad was one of the joys of Hutt's existence. Difficulties or discomforts in the means of travel never dismayed him, and he would be happy even to tramp rather than miss an interesting place or people. He had an intimate knowledge of many parts of the Continent, and often while on holiday made a point of studying health administration and institutions in different lands. These visits were afterwards recorded in such journals as *Health*, *National Health*, etc. Possessed of a wide and detailed knowledge of the whole subject of public health, he was able, as a lecturer to the D.P.H. students of the Royal Institute of Public Health and to the undergraduates at Charing Cross Hospital, to present the subject in an illuminating and impressive manner.

He was a man of the most kindly and generous disposition, always willing and helpful if approached, but extremely modest and most unwilling to thrust himself forward. As an old friend once wrote of him: "An unassuming worker whose quiet endeavours to gather knowledge and to aid others inspire his colleagues with a sense of fellowship and partnership in the common work." He retained his youthful appearance, and sometimes associated with it a delightfully boyish shyness. Rarely did he speak harshly of anyone, and even for those who might occasionally merit a bitter word he almost apologized with a deprecating smile. He applied to the problems of public health a finely imaginative and constructive mind; his outlook on the issues which emerge in the unfolding of this scroll of knowledge was philosophic. Hutt looked across and beyond the questions of the hour to the horizon of the future, and the ideas he expressed were the products of a highly cultivated intellect. But he likewise possessed the ability to put those ideas into practical form, and many a scheme which he

has brought into execution serves, and has served, as a useful pattern to others. He was whole-heartedly devoted to his profession, and there is little doubt that he sacrificed his life to a passion for work. His health had broken down earlier in the year, and he returned after a period of rest and change, but far from fully recovered. The demands of his official work and those entailed by the completion of his latest textbook were more than an already overtaxed constitution could bear. So he has passed on in middle life while intellectually at the height of his powers, leaving behind him the sincere regrets of many friends and colleagues.

E. D. MACNAMARA, M.D., F.R.C.P.

Consulting Physician for Psychological Medicine, Charing Cross Hospital

We regret to record the death, on August 24th, at the age of 64, of Dr. Eric Danvers Macnamara, the well-known psychiatrist. He had had a busy life. After taking the ordinary qualification of the English Royal Colleges in 1897, he became a surgeon in the Royal Navy for five years or more. During his term of service he was almost exclusively attached to the China Squadron, and served in the Pekin relief force, for which he obtained a medal and clasp. But surgical life in the Navy was so distasteful to him that he resigned rather than remain another couple of years to qualify for a pension. He then graduated at Cambridge, taking the M.B., B.Ch. in 1903 and the doctorate in 1908. It was then that he switched over to medicine, and became particularly interested in mental diseases; the clinical aspects of which he first studied as house-physician to Bethlem Royal Hospital. With the same object in view he became house-physician to the National Hospital in Queen Square, neurology and psychiatry being supposed, in those days, to be more intimately related than they are to-day. He was appointed assistant physician to Westminster Hospital, his Alma Mater, where he subsequently became dean of the medical school, and he had many other appointments to keep him busy. He was on the staff of the West End Hospital for Nervous Diseases and the Paddington Green Hospital for Sick Children. He was lecturer on mental diseases to Charing Cross Hospital, and gave post-graduate lectures regularly at Bethlem Royal Hospital. At one time he was examiner in psychology to the Conjoint Board of the Royal Colleges of Physicians and Surgeons. During the war he served in the R.A.M.C. and also in the Medical Department of the Admiralty. His contributions to medical literature appear to have been almost limited to articles in various encyclopaedias of medicine: Latham and English's *System of Treatment*, *The Practitioner's Encyclopaedia*, the *Dictionary of Practical Medicine*, and Price's *Textbook of Medicine*.

Macnamara was a cheery companion, but had a very retiring nature. He devoted his life to mental disease, and was unusually devoid of such hobbies as would have brought him into more intimate contact with his fellows. Even his domestic life had many associations with his special study. He married Frances Mary, daughter of Dr. W. Simpson Craig, who was proprietor and superintendent of Bishopstone House, a successful private mental home in Bedford, and sister of Sir Maurice Craig, with whom Macnamara collaborated in several of the above-mentioned articles. He leaves two sons.

Surgeon Commander G. ERNEST MACLEOD, R.N. (ret.), writes: The medical profession has sustained a great loss by the recent untimely death, after a short illness, of Eric Danvers Macnamara. A man of attractive presence and exceptionally charming personality, his quiet, unassuming manner concealed the outstanding ability and wide

sympathies which he possessed and devoted in such full measure to that department of medicine which he had made his own. To an extensive knowledge of men and matters he added a keen sense of humour, an enjoyment of life, and an optimistic outlook on affairs generally, which made him a most delightful companion. On his academic and professional attainments it would be superfluous to dwell, but I think it is no exaggeration to say that his name and work will long be remembered with affection and gratitude by patients, students, and colleagues alike. My friendship with him began many years ago, when we entered the medical department of the Navy together, and has continued ever since, and it is less than three weeks since I last had one of his usual cheery letters, in reply to one of mine, in which he asked me to hurry up and come to town again soon for one of our periodical dinner-and-theatre meetings which were always such a great pleasure, and to which I was looking forward. It is painfully sad to think that we shall not meet again.

C. C. ELLIOTT, M.D.ONT., F.R.C.S.ED.

Dr. Charles Coyne Elliott, who died on August 10th, had had a varied and interesting career before settling in general practice in Leicester. Born and educated in London, Ontario, his intellectual gifts manifested themselves very early. In fact, his contemporaries in the Medical School remember him as "the man who made one mistake," for he was said to have only once answered a question incorrectly. He took his M.D. degree in 1900, at the same time winning a gold medal, which had not been awarded for so many years that the possibility of securing it had almost been forgotten. After a few years' practice in Canada, Elliott went to China as a medical missionary, and found great scope for his scientific attainments in the treatment of patients in the extreme Western Province of Szechuan. Before his day it had not been recognized that the many severe cases of anaemia were due to ankylostomiasis, and he was the first to understand that the terrible abdominal pain "which ceases at cock-crow" was due to duodenal ulcer. He contributed to the *China Medical Journal*, September, 1918, a study of forty cases of duodenal and gastric ulcer submitted to operation. Dr. Elliott was very successful in training male medical students and nurses, and the hospital which he built was a model of economy, efficiency, and thoroughly scientific method. As time went on it became clear to him that medical students needed more than the spare time of a busy doctor, and he decided to throw in his lot with the medical school in Chengtu, where he taught clinical surgery. He was very successful in gaining the respect and affection of the Chinese medical students (not, at that time, a very amenable class of men), and many of those whom he taught are now doing most excellent work.

He used some of his time on furlough to obtain the F.R.C.S. at Edinburgh (1913), and on his last return from China spent time in study at University College Hospital and in Paris with a view to maintaining the high standard of the West China Union University in Chengtu. It was only the pressure of domestic affairs which forced him to abandon his intention of returning to China.

Dr. JOHN TERTIUS CLARKE died at his home in Harrow on August 31st at the age of 69. Born at Hinckley, Leicestershire, in 1865, Clarke was educated at Dulwich College and St. Thomas's Hospital, and qualified M.R.C.S., L.R.C.P. in 1889. In 1891 he became house-surgeon to the Royal Hants County Hospital, Winchester, where he met his future wife, Miss Mary F. Cosgrove. He served as ship surgeon for two years, and in 1896 he joined the

Perak Medical Service. In 1906 he took the D.P.H. Cantab. and became medical officer in the public health department, Federated Malay States, in 1911. In 1920 he retired from the service, but remained in Malaya till 1926, carrying on an extensive practice on various rubber estates, the work consisting chiefly of the prevention of malaria and ankylostomiasis. In 1926 his heart began to trouble him seriously, and he came home to England via Canada. On his way home he was taken very seriously ill in British Columbia, but recovered, and through his indomitable pluck was able to lead a life of useful though restricted activity for another eight years. Clarke was impressed by the rarity of rheumatic fever in the Tropics, and during his eight years at Harrow he worked at the Ross Institute at Putney, carrying out researches into the causes of rheumatic fever. He wrote several articles in the *British Medical Journal* in support of his theory that rheumatic fever is transmitted by sewer rats. He was also much interested in the research work on cancer of the late Dr. Shaw Mackenzie, and gave him great help and encouragement in his labours. Tertius Clarke was keen on the work of the British Medical Association, and was a constant attendant at meetings of the Harrow Division while his health permitted; he served as honorary secretary in 1929-30. The Malaya Branch elected him a complimentary member. He broke his thigh at the age of 15 and could never afterwards move quickly enough to excel at active games, but he was a keen golfer and no mean performer. His courage and keen sense of humour in the face of grave physical disability endeared him to all who met him, and their sympathy will go out in abundant measure to his widow and two sons.

The death took place suddenly at Buxton, on August 30th, of Dr. DAVID DUNCAN MAIN, who for many years was one of the best-known missionaries in China. Dr. Main was born at Kirkmichael in 1856, and after studying medicine in Glasgow and Edinburgh took the triple qualification of the Scottish Corporations in 1881. He immediately began work as a medical missionary in China, and from 1881 to 1927 was superintendent of the Church Missionary Society Medical Mission at Hangchow, and principal of the Hangchow Medical Training College. Here he was in charge of a large hospital, and was the head of a native medical school where many hundred Chinese men and women were trained for medical work. He organized a centre for training in industrial work, at which the mission provided practical instruction for masons, carpenters, tinsmiths, painters, etc., and inaugurated sanatoria for convalescents and tuberculous patients, and a leper hospital. During intervals of return to his native country Dr. Main took the Membership of the Royal College of Physicians at Edinburgh in 1901, proceeding to the Fellowship in 1905; in 1911 he joined the Royal College of Surgeons of Edinburgh as a Fellow. In addition to his active practical work he rendered valuable service to Chinese medicine by translating several medical works into Chinese, including *Whitla's Dictionary of Treatment*, Caird and Cathcart's *Surgical Handbook*, and Playfair's *Midwifery*. For his services to China he received various high decorations from the Republic; he was also decorated as a Fifth Class Mandarin by the Emperor of China in 1901. In 1927, after forty-five years of continuous work in China, he settled in Edinburgh, where he took considerable interest in the medical life of the city. The interment took place in the Dean Cemetery, Edinburgh, on September 4th.

We regret to announce the death of Dr. ANNIE T. LEIGH, the wife of Mr. J. R. Johnson of School Road, Sale, Cheshire. Dr. Leigh qualified M.B., Ch.B. in 1925 at Manchester, and took the diplomas of M.R.C.S. and L.R.C.P. in 1926. She devoted the whole of her time to anaesthetics, and before qualifying she began research work with the late Dr. S. R. Wilson, and continued with him in this work till his tragic death. Her first appointment was as visiting anaesthetist to the Manchester Royal Infirmary (Central Branch). After the

death of Dr. S. R. Wilson she was appointed to his post of honorary anaesthetist to the Manchester Dental Hospital, and was a member of the Board. At the time of her death Dr. Leigh was also honorary anaesthetist to St. Mary's Hospital, Whitworth Street, visiting anaesthetist to St. Mary's, High Street, and to the Northern Hospital for Women and Children. She had only recently been appointed by the Manchester Corporation as visiting anaesthetist to Booth Hall Infirmary. Dr. Leigh was also a medical examiner for the Sun Life of Canada Assurance Co., Ltd. She was the sister of Dr. Gertrude B. Leigh of Sunderland. Her death came as a great shock to her medical friends.

We regret to record the death of Dr. EDWARD BUXTON at Jersey on August 25th. Dr. Buxton qualified L.R.C.P.Ed. and M.R.C.S. in 1885, and took the diploma of M.R.C.P.Ed. in 1893 and F.R.C.S.Ed. in 1894, and the D.P.H. in 1892. In 1897 he received the degree of M.D.St.And. Dr. Buxton was an honorary life member of the St. John Ambulance Association, and had been a member of the British Medical Association for forty-eight years. At one time he was physician to the Nazareth House Orphanage, Great Crosby, and medical officer of health for the Little Crosby Urban District Council. He had retired from practice for some years. Dr. Buxton was of a genial disposition and had many friends. He leaves a widow, one son, and one daughter.

The death is announced, on August 10th, of Dr. RUDOLF BOLLING TEUSLER of St. Luke's International Hospital, Tokyo, who was one of the leading figures in the foreign community in Japan. Dr. Teusler, who was a cousin of Mrs. Woodrow Wilson, was born at Rome, Georgia, in 1876. He died at St. Luke's, the hospital and public health institution which he founded as a small eight-roomed mission hospital when he went to Japan for the American Episcopal Church in 1900. After graduating M.D. at the Medical College of Virginia he was in private practice and on the teaching staff of his college. His little hospital grew to a great institution, the training school for nurses being approved by the Japanese Government as the college for nurses. To Dr. Teusler more than to anyone else was due the raising of the status of the nursing profession in Japan, while he was also a pioneer with regard to children's clinics and the provision of visiting nurses in poor districts. In the earthquake of 1923 his hospital was destroyed, but the foundations for a new building, which had just been completed, remained intact, and the site became a refugee centre where medical aid of all sorts was given. The present buildings were opened and dedicated last year. In all his work Dr. Teusler was aided by a fine band of Japanese colleagues, who at the present time include leading specialists in almost every branch of medicine and surgery. It is illustrative of the regard for him that he was referred to by friends as "Sir Galahad." Teusler was decorated with the Fifth Class Order of the Rising Sun, the Russian Order of St. Vladimir, and the Czechoslovak war medal, which were awarded him for his work with the American Red Cross in Siberia from 1918 to 1921, and for the evacuation of Czech invalid prisoners from Siberia.

The following well-known foreign medical practitioners have recently died: Dr. EUGENIO TANZI, professor of psychiatry and neurology at Florence, aged 78; Professor E. JOSEPH, a Berlin urologist; Dr. GASCARD, professor at the Rouen medical school and national correspondent of the Académie de Médecine in the Section of Surgery; Dr. LOUSTE, general secretary of the Société Française de Dermatologie; Hofrat Professor Dr. HERMANN SCHLESINGER, head of the third medical department of the General Hospital at Vienna, aged 68; Dr. C. C. DELPRAT, a former editor of *Nederlandsch Tijdschrift voor Geneeskunde*, aged 79; and Dr. ERNEST SCOTT, professor of pathology, Ohio State University College of Medicine, since 1915, aged 58.

Medical News

The annual prize distribution at St. George's Hospital Medical School will be held in the Board Room of the hospital on Monday, October 1st, at 3 p.m., when Professor W. Langdon Brown will deliver the inaugural address.

The Central London Throat, Nose, and Ear Hospital (Gray's Inn Road, W.C.) has arranged an intensive course in laryngology, rhinology, and otology from October 1st to 27th. The course includes an anatomy and physiology class, an operative surgery class, a practical course in peroral endoscopy, and a course in pathology and bacteriology (specially suitable for D.L.O. students). The fee for the whole course is £21, but classes may be taken separately. Full particulars may be obtained from the secretary-superintendent.

On Tuesday, September 18th, a play called "Muggleston on the Map," by A. V. Williams and Ernest Milligan, will be broadcast from the North Regional radio station (Manchester) in the night programme. This play is a municipal comedy, with a special appeal also to football "fans." Dr. Milligan is M.O.H. for the borough of Glossop, and "The Ballad Singer," an Ulster comedy written by him, was broadcast in 1933 from Belfast.

The jubilee meeting of the Medical Officers of Schools Association will be held at Eastbourne on Friday and Saturday, September 14th and 15th, by invitation of the mayor and council of the county borough of Eastbourne. There will be a paper by Dr. J. Alison Glover and Dr. Fred Griffith on "Acute Streptococcal Throat Infections," on September 15th, at 10 a.m., at the Town Hall, Grove Road, Eastbourne.

A lecture on the theory and practice of contraception will be given to medical students who have completed their gynaecological course and practitioners by Dr. Gladys Cox on Friday, September 14th, at 6 p.m., at the Walworth Women's Welfare Centre, 153A, East Street, S.E.17. Practical demonstrations will be given on each subsequent Friday till September 28th (inclusive). Tickets admitting to the lecture (5s.) are to be applied for in advance.

Instruction to post-graduates and medical students in the theory and practice of contraception will be given at the North Kensington Women's Welfare Centre (12, Telford Road, Ladbroke Grove, W.10) during the next three months. Particulars may be had from the secretary.

The Fellowship of Medicine and Post-Graduate Medical Association announces further lecture-demonstrations at 11, Chandos Street, W., at 2.30 p.m., on September 11th (chronic cough) and September 18th (hemiplegia). There will be a "refresher" course in medicine, surgery, and the specialties at the Westminster Hospital, from September 17th to 29th. Other forthcoming courses include diseases of the chest at the Brompton Hospital, September 24th to 29th, and, during the same period, proctology at the Gordon Hospital; diseases of children at the Queen's Hospital, October 1st to 13th; dermatology at St. John's Hospital, October 1st to 27th; physical medicine (evening course) at the St. John Clinic and Institute of Physical Medicine, October 1st to 27th; cardiology at the National Heart Hospital, October 8th to 20th; medicine, surgery, and the specialties at the Metropolitan Hospital, October 8th to 21st.

A conference of some of the leading paediatricians of the world will be held at Lyons on September 27th and 28th. The conference, which will deal specially with the prevention of malaria, rickets, and convulsions, has been organized by the International Association for Preventive Paediatrics, which is the medical section of the Save the Children International Union. The British representative on its council is Dr. Leonard Findlay.

The twelfth Rumanian Congress for oto-rhino-laryngology will be held at Bucarest from September 28th to 30th. Discussions have been arranged on thrombosis of the lateral sinus and balneotherapy in oto-rhino-laryngology.

According to a correspondent writing in the *Times* of September 5th, Dr. W. von Brehmer, head of the anatomical laboratory of the Reich Biological Institute at Dahlem, believes that he has proved cancer to be a bacterial disease, having discovered, isolated, and transplanted a visible organism, to which he gives the name of *Siphonospora polymorpha*. This bacterium exists in close contact with the erythrocytes in cancerous subjects, and its discovery is associated with the observation that the disease occurs only in cases where the blood shows a strong alkaline content. Tumours have been produced in inoculated animals, and seven stages in the development of the organism are described.

The National Smoke Abatement Society announces that the sixth annual conference will be held at Glasgow, in conjunction with the Scottish Branch, on September 27th, 28th, and 29th. Papers will be read by Professor J.-R. Currie, Dr. J. S. Owens, Messrs. W. J. Grassie, O. Cochran, W. D. Besant, and Dr. J. J. Jervis. The conference headquarters will be the North British Station Hotel, George Square; further information may be obtained from the secretary, National Smoke Abatement Society, 36, King Street, Manchester.

The fifteenth congress of the Italian Paediatric Society will be held at Sienna from September 19th to 22nd, when the following subjects will be discussed: the autonomic nervous system in childhood, introduced by Drs. G. Careddu and B. Trambusti; septicæmia in newborn infants, introduced by Drs. A. Bocchini, M. Gerbasi, and R. Vaglio; and indications for climatotherapy in childhood, introduced by Drs. G. C. Bentivoglio, A. Foa, and L. Maghi.

The Societas Oto-rhino-laryngologica Latina will hold its fourth congress at Brussels from September 20th to 24th, under the presidency of Dr. Buys. Further information can be obtained from the secretary, Dr. Vues, Rue de Livourne 9, Brussels.

The annual congress of the Chartered Society of Massage and Medical Gymnastics will be held from September 24th to 28th, and all lectures and demonstrations will be given at Bedford College for Women, Regent's Park, N.W. Registered medical practitioners will be admitted free of charge to the lectures and demonstrations, for which a card of admission may be obtained from the offices of the society, Tavistock House (North), Tavistock Square, W.C. The annual dinner of the society will be held at the Café Royal, Regent Street, W., on Wednesday, September 26th, at 7.30 p.m. On Friday, September 28th, at 8.30 p.m., the Founders' Lecture will be delivered by Sir Humphry Rolleston, on "Occupational Diseases of Those in Attendance on the Sick."

The National Children's Home and Orphanage, whose head office is at Highbury Park, London, N.5, has issued invitations to the opening of the new wing at the sanatorium, Harpenden, on Saturday, September 22nd, at 2.45 p.m., by Dame Janet Campbell. The chair will be taken by Sir Thomas Barlow.

The address of the British Empire Leprosy Relief Association has been changed to 131, Baker Street, W.1 (telephone, Welbeck 5913).

We are asked to announce that the new edition of the *Belfast Hospitals' Pharmacopœia*, revised and brought up to date with the collaboration of the medical profession and issued by the Ulster Retail Drug Trade Association, came into official use on September 1st. Copies are obtainable from the principal Belfast booksellers and wholesale drug establishments.

An epidemic of acute poliomyelitis, threatening to reach large proportions, is reported from Denmark, where cases have been notified in Faaborg, Odense, and elsewhere. Preventive measures have been adopted, and the Lister Institute, London, on a telegraphic request from Professor Madsen of Copenhagen, recently dispatched 800 ampoules of its anti-serum (horse). Given intramuscularly in 5 c.cm. doses this is believed to offer the best prophylaxis, giving passive immunity for about three weeks. Statistics illustrating its effect in the present epidemic will be awaited with interest.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to The EDITOR, British Medical Journal, B.M.A. House, Tavistock Square, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBER of the British Medical Association and the *British Medical Journal* is EUSTON 2111 (internal exchange, four lines).

The TELEGRAPHIC ADDRESSES are:

EDITOR OF THE BRITISH MEDICAL JOURNAL, Aitiology Westcent, London.

FINANCIAL SECRETARY AND BUSINESS MANAGER

(Advertisements, etc.), Articulate Westcent, London.

MEDICAL SECRETARY, Mediscera Westcent, London.

The address of the Irish Office of the British Medical Association is 18, Kildare Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 62530 Dublin), and of the Scottish Office, 7, Drumshough Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 24361 Edinburgh).

QUERIES AND ANSWERS

Earth Burials and Disease

Dr. CHRISTOPHER ROLLESTON (Stamford) writes: I should be glad to know if there is any modern evidence that earth burials cause disease. On looking through the literature on the subject all the evidence seems to go back to the pre-bacteriological era. I should be glad to know whether any epidemics have been traced to this cause in recent years. I have Thompson's book on *Cremation*, but that, of course, is an ancient book.

Over-smoking

"E. T. P." (Orpington), in reply to "F. C. R." (Sussex), writes: I found (when I was in general practice) invariable success with the following plan. Ascertain as exactly as possible how many cigarettes per day the patient smokes; if this number was fifty direct him to fill his box or case first thing in the morning with forty-nine, carry that around with him, and make it do for that day. Repeat this process for perhaps two days, and on the third put only forty-eight in the case. As time goes on and the number per day decreases, the interval between the "decreases" must be increased. A smoker will not really notice the loss of one cigarette in one day when the difference is between fifty and forty-nine, but when he has dropped from forty-nine to forty-five he should keep at the forty-five for several days before dropping to forty-four, and so on. I would emphasize the importance of exact instruction as to the number of cigarettes and the number of days' interval, and of the personal interest of the doctor in asking for the patient's report as to how conscientiously the directions have been carried out. This method takes time; in fact, it must be allowed to take so much time that the patient does not know he has been deprived of one cigarette every so many days.

Removal of Tattoo Marks

Dr. E. BAYLIS ASH (Birmingham) writes in reply to Dr. George Steane's inquiry: Three methods are available: (1) excision of the mark and skin grafting gives a moderately good result in small tattoo marks up to two inches square; (2) freezing with CO₂ snow in fairly new tattoo marks results in a scarred area hardly discernible after a year; (3) old tattoo marks, particularly those containing red and yellow pigments, are best removed with a fine spark of the diathermy needle. Numerous treatments are necessary, and the scar is rather more pitted than that from the CO₂, but quite good when examined after two years. The treatment is tedious, and requires a good deal of patience on the part of the medical man and the patient.

Income Tax**Expenses of Assistant**

"J. K." was an assistant to August, 1932, using two rooms of his house for seeing patients; his maid had to answer the door and telephone. Since August, 1932, he has held another assistantship, his principal making it a condition that he rents the flat over the surgery and keeps a competent maid to answer telephone calls and take messages for the practice. He puts his car expenses at £150 a year, including depreciation, but excluding running costs during holidays.

* * The expenses of the maid's services are partly private and the amount deductible professionally is a fair proportion having regard, *inter alia*, to the time expended by her on the two classes of work. Probably one-third would not be unfair to "J. K." as a professional charge. As regards the rent the same proportion might be claimed in the first case, but in his present circumstances apparently no part of the flat is used for the reception of patients and no part of the rent will be allowed. Apparently practically the whole of the £150 car expenses will be allowable, but "J. K." will have to show the amount of depreciation claimed as a separate item, and some slight restriction of that claim may be due in respect of holiday use of the car.

LETTERS, NOTES, ETC.**English Children in the Alps**

The Queen Alexandra Sanatorium Fund, which owes its origin to the appeal for an English sanatorium in Davos made by the late Lord Balfour of Burleigh thirty years ago, has investments valued at £64,000 and an annual income of about £2,400. Since the sanatorium was given up as a war-time necessity the income has been used to enable patients of small means suffering from curable tuberculosis to stay long enough in Davos to make a substantial recovery. Last year the number of suitable cases applying was not very large, and it was possible to extend the grants for more than the usual five or six months on medical advice in Davos; but the council of the fund in London recognizes that a limited stay in the Alps, particularly if it must be followed by a return to straitened conditions at home, does not produce the best possible return for expenditure. For the last two years the council has had an object-lesson of a different kind in the Davos Valley. By the generosity of the president of the Birmingham Children's Hospital, acting in concert with its staff, a group of forty or more Birmingham children have spent several months in the Alps, with results which have been critically watched by a number of British and foreign paediatricians. About one-half of these children had various forms of surgical tuberculosis; the remainder illnesses such as asthma, interstitial pneumonia, recurrent bronchitis, debility, and malnutrition after prolonged ill-health. When last reported, of the eighty children who had been to Switzerland forty-one were discharged "cured" after a stay averaging seven months, and at a weekly cost per patient of £2 2s. 6d. The experiment having surpassed the expectations of its promoters, the council of the Queen Alexandra Fund, a year ago, adopted the principle of helping children. At that time negotiations for collaboration with the Birmingham scheme did not mature and the money was allowed to accumulate, so that for the coming year there is a larger balance, and the council has agreed to allot, if suitable cases offer, as much as half its available income for the purpose. No hard-and-fast rules have yet been laid down as to the qualifications for a child candidate. The fund's honorary examining physicians in London will decide on its merits any application received for help from the fund, which now has the benefit of the advice of Professor L. G. Parsons, who was elected a member of council at the recent meeting. Practitioners with youthful patients who would, they think, benefit under the scheme may obtain further information from the honorary secretary of the council, Mr. A. Stanley Herbert, 25, Birch Lane, E.C.3, or from the local secretary, Mr. W. G. Lockett, Davos-platz, Switzerland.

Conan Doyle, Bell, and Laycock

Dr. T. JOHNSTONE (Ilkley) writes: We have heard much of Sir A. Conan Doyle and Mr. Joseph Bell, but nothing from either as to who was Joe Bell's teacher. He was Professor Laycock, the first Englishman appointed to a medical chair in the University of Edinburgh, and who, all his life, was simply persecuted by some of his colleagues, both privately and in public. Their behaviour

is recorded in a book or collection by the late Dr Stark Currie, and was presented by me to the library Morningside Mental Hospital, then under the care of Professor Robertson, who intended, had he lived, to produce a lecture on, or short biography of, Laycock. He was a remarkable man, a teacher at the old York medical school, where his pupils included Sir Jonathan Hutchinson and Hughlings Jackson, and he was friendly to Sir Clifford Allbutt. In Edinburgh he inspired, and had his full share in teaching, such men as Sir David Ferrier, Sir Dyce Duckworth, and Sir Lauder Brunton. Laycock was a pioneer in psychology and mental ailments, and did much to simplify the lunacy laws. He taught that people could carry the "poison" of diphtheria and give it to others, though they themselves escaped. He drew our attention to the effects of poisons on the nervous system after the exanthemata or injuries, and, instead of shell-shock, we were taught of "cannon fever" as the cause of nervous troubles after a war. Some of his teachings were wonderful, and time has verified many. He used to teach us physiological diagnosis and many other things, by observation and inference. I wonder what he thought of Joe Bell? Time, education, and evolution have widened the outlook of the men who select the medical professors at my old university, and I will merely mention my old teachers, Sir William Turner and Lord Lister.

"Praise and Dispraise of Doctors"

Dr. J. N. DUGDALE (Johore Bahru, Malaya) writes: I was interested to read (*Journal*, June 30th, p. 1172) the quotation of the Latin epigram attributed to Euricius Cordus in Dr. Hutchinson's illuminating MacAlister Lecture. It reads: "Three faces the physician hath . . . first as an angel . . . next . . . a god . . . and last of all . . . a very fiend of hell." Some time ago a Chinese patient described to me a cartoon in a Chinese paper in which the physician is depicted as an angel on arrival at the sick-bed, a god on recovery of the patient, but as a demon when he sent in the bill! Many Chinese maxims are similar to our own, and it would be interesting to know if they had a common origin.

Transport of Invalids by Railway

Dr. MAURICE CAMPBELL (London, W.1) writes: In these days, when motors are almost universal, I am not sure if doctors realize how easily patients can travel by train. Recently a friend of mine had to come from Manchester to London, and I was surprised at the comfort, or even luxury, of the invalid coach. He was, indeed, more shaken in a ten-mile motor ambulance journey than on the rest of the way. He had the additional advantages of meals and of seeing the country after many weeks in bed, and greatly enjoyed the day. Patients may be deterred by the thought of the cost, but this was most reasonable. I am sure no one who has experience of this will ever be willing to travel any other way.

Autoclaving of Gum-elastic Catheters

Dr. MALCOLM BAILLIE (Urological Department, King's College Hospital, S.E.5) writes: We have found that the brown gum-elastic Eynard urethral catheters will stand indefinitely repeated autoclaving, and when cool have lost none of their stiffness. This method of sterilization recommends itself by its saving of labour and killing of all organisms, including spores.

Surgical Films at the Annual Meeting**Acknowledgement**

In the Section of Surgery at the Annual Meeting of the British Medical Association at Bournemouth cinematographic films were lent by Sir John Thomson-Walker, Mr. Tudor Edwards, and Professor G. Grey Turner, dealing respectively with prostatectomy, lobectomy, and construction of an extrathoracic oesophagus after oesophagectomy. These were highly appreciated on the several occasions on which they were shown.

The Medical Supply Association, Ltd. (167-73, Gray's Inn Road, W.C.1), inform us that they are opening new show-rooms at 95, Wimpole Street, W.1 (opposite the Royal Society of Medicine).

Vacancies

Notifications of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 35, 36, 37, 38, 39, 42, and 43 of our advertisement columns, and advertisements as to partnerships, assistantships, and locum tenencies at pages 40 and 41. A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 164.

BRITISH MEDICAL JOURNAL

LONDON: SATURDAY, SEPTEMBER 15th, 1934

DIFFERENTIAL DIAGNOSIS OF FUNCTIONAL AND ORGANIC NERVOUS DISORDERS*

BY

GEORGE RIDDOCH, M.D., F.R.C.P.

PHYSICIAN WITH CHARGE OF OUT-PATIENTS, LONDON HOSPITAL, AND NATIONAL HOSPITAL, QUEEN SQUARE

It would be well at the outset of the discussion to define the terms "functional" and "organic." Strictly speaking, all symptoms of illness are, of course, functional, in that they are manifestations of disordered function; but here I propose to use the word in a narrower sense as indicating those symptoms which are psychogenic. By "organic" will be meant symptoms which result from abnormal physical alterations in the nervous system. The word "abnormal" is advisedly used, for all forms of activity of the nervous system must be associated with physical changes. These morbid alterations may be so gross that they can easily be detected by the pathologist, and have long been recognized. Others are less obvious, and, like those in the basal ganglia in paralysis agitans, have only come to light in recent years through the development of histological technique. There is still another group of cases in which the symptom is believed to be organic, although structural changes may or may not be found post mortem; this group is largely composed of disorders of function which are transient and recurrent. During the attacks there may be present signs which are accepted as of organic significance—for example, in epilepsy, loss of consciousness, abolition of tendon reflexes, or extensor plantar responses—while in others, such as narcolepsy, there may be no physical signs of this order.

It is therefore clear that, although the pathologist has done much in the differentiation of organic from functional nervous disorders, the main burden has rested on the clinician, and still does. By the sifting of accumulated experience gained at the bedside, through careful investigation of the natural history of disorders, the characteristics of individual symptoms, and the searching for physical signs, he has led the way in differential diagnosis. The physical signs of organic disease are often crude and are comparatively few, but they are gradually becoming more refined and are increasing in number. But it is not only on the elicitation of physical signs that the physician ought to depend for differential diagnosis. Symptoms, including the patient's own sensations, have for long been taken seriously by the clinician, and will, in the future, yield information of the greatest value, for frequently they indicate the earliest stages of disordered function before structural changes develop of sufficient severity to give rise to physical signs. This leads up to the importance of careful history-taking, the methodical investigation of symptoms, and their temporal relationships. An adequate history should, of course, include an account of the patient's past illnesses and his habits,

and of the health of his family. One should, in addition, attempt to get some idea of the main psychological influences that have affected him, particularly if diagnosis is uncertain. In other words, a proper medical history is one which recapitulates the life of the patient as a whole, of which his present illness forms but a part. "Disease" is a vital process with a natural history, and symptoms are not a series of isolated events.

Clinical Criteria of Differential Diagnosis

What, then, are the indications which have been proven to be of use in the separation of functional and organic nervous illnesses? The psychological aspect of the problem will be dealt with by Dr. Petrie, but let me say that the history of a psychoneurotic almost always shows a tendency, from childhood onwards, to face trouble badly. In the past, he may have been able to carry on with his work, and may not have broken down before; nevertheless, emotional disturbances have produced symptoms of a psychogenic kind. In fact, to borrow a definition, a neurotic is a person who is unable to strike a sensible bargain with existence. Dr. T. A. Ross, as the result of his great experience, stresses this point by saying that in an obscure case the diagnosis of a psychoneurosis should not be made in the absence of a psychogenic history. It may be argued, with justice, that every individual has his breaking-point, and that an anxiety, resulting from a threat to himself or to those to whom he is deeply attached, may precipitate a mental illness. But it is questionable whether the illness would persist for long if the individual possessed an average capacity for adaptation as shown by his behaviour in the past. If the present illness was not preceded by emotional strain, and if the past history shows that the ill person had passed through experiences distressing to him, and yet was able to adjust himself to them in an adequate manner, the symptoms which now trouble him, however much they may resemble those of a psychoneurosis, should not readily be accepted as such.

For example, sleeplessness at night with or without lethargy during the day is now a well-recognized symptom of lesions of the hypothalamus from various causes, and, when due to encephalitis lethargica, is often, especially in children, associated with irritability, tearfulness, and fear. Fatigability, a common complaint in neurotic persons, may also be an organic manifestation, as in Parkinsonism and myasthenia gravis. Certain headaches—for instance, those of intracranial hypertension—pains in the trunk and limbs as in tabes or polyneuritis, and the paraesthesia in subacute combined degeneration, are of the same order, but a careful analysis of such symptoms in the process of history-taking and a knowledge of features

* Read in opening a discussion in the Section of Neurology, Psychological Medicine, and Mental Diseases at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

of organic significance should prevent many mistakes in diagnosis.

A single symptom such as sudden diplopia or misty vision in one eye, which persists for a few weeks, ought, especially in a young adult, to make one suspect organic disease. This suspicion becomes almost a certainty that one is dealing with a case of disseminated sclerosis if, as the story is unfolded, other transient disorders, like numbness and clumsiness of a limb, or hesitancy of micturition, are found to have occurred even after intervals of many years of good health, in spite of a complaint from the relatives, that the patient has become more emotional than before. This symptom in itself is significant in such a story, for it is common for patients with disseminated sclerosis to laugh or cry too easily, and has undoubtedly an organic basis. To stress the meaning of a history of this kind is perhaps to underline the obvious, if it is supported by the presence of physical signs; but experience has shown that its diagnostic importance is not much diminished by the absence of physical abnormalities. They will almost certainly appear later.

Physical Signs

Coming to the physical signs of neurotic ailments, we can put to one side the exaggerated reactions to fear, at the same time remembering that they may be indications of mild hyperthyroidism, which is often mistaken for a psychoneurosis. It is sometimes difficult, or impossible, to say which is primary—the glandular disorder or the anxiety state. Long-continued emotional stress seems to stimulate thyroidal activity, and it may be said with some reason that the naturally over-anxious person has also, as a part of his heritage, an abnormally active thyroid gland. This association probably determines the onset of illness in many women who break down at the climacteric. The major part of the symptomatology of the so-called menopausal neurosis as well as the physical signs are those with which we are familiar at earlier periods of life in cases of mild hyperthyroidism. The neurotic physical signs which will be particularly discussed are those of hysteria. From the point of view of physical examination the diagnosis of hysteria rests on: (1) the absence of signs of organic disease; and (2) the presence of positive signs of hysteria.

Certain manifestations are invariably organic in origin. Of these the most important are dysphasia with or without dysgraphia, papilloedema and optic atrophy, nystagmus with the slow movement towards the rest position and the quick movement towards the object of fixation, absence of vestibular reactions, local muscular atrophy with alteration in the electrical excitability coming on within a few weeks of the onset of paralysis, inequality of the abdominal reflexes or the tendon jerks or abolition of the latter (the abdominal reflexes are difficult to obtain in people with lax abdominal walls), and a true extensor plantar reflex.

Many sensory abnormalities are of equal value. Some only will be mentioned, and others will be referred to later. Of defects in the visual fields, central scotoma for red and green, with reduction of visual acuity and homonymous or bitemporal field defects, especially if quadrantic, are important; so also is pain which consistently is in the distribution of spinal posterior roots, all the more if it is associated with cutaneous tenderness or sensory loss. There are other pains, such as those of tic douloureux and the lightning pain of tabes, and the neuralgias of the head and face, due to sinus infection, which have features of their own. Certain varieties of sensory dissociation occur only from organic lesions. Obvious examples are the analgesia and thermo-anaesthesia of segmental distribution with preserva-

tion of tactile sensibility in syringomyelia and other central lesions of the spinal cord, and loss of postural sensibility with ataxia, diminished vibratory sense, and astereognosis as the predominant sensory defects from posterior column lesions.

To the unwary, however, some of these physical signs may appear to be present, whereas they are the result of faulty methods of examination or a lack of familiarity with normal variations. Thus, in testing the tendon jerks, care must be taken that the two limbs which are being compared are in the same position and the muscles relaxed. In regard to the plantar reflex, most stress should be laid on the response obtained from the outer edge of the sole, which is the focus of the receptive field for the reflex. With slight lesions of the pyramidal tract the abnormal reaction may be obtained only from this part, and stimulation of the rest of the sole may yield the normal downward movement of the toes. In doubtful cases help is usually obtained by observation of the reaction of the rest of the limb to plantar stimulation. In normal people who are not over-sensitive, the flexor plantar response is often accompanied by a quick contraction of the muscles in front of the thigh, whereas if the reflex is organically abnormal, whether the toes move up or fail to move, the limb flexors tend to contract. This contraction can be best appreciated in the hamstrings by feeling their tendons tighten. If then the toe response is different on the two sides, observation of the effects of the response on the quadriceps and hamstrings in each limb is often helpful. If the patient is over-sensitive, and especially if the stimulus is painful and applied roughly without due warning, the reaction in the limb is likely to be a sudden flexion or withdrawal of the limb, and the toes may either extend or flex. This is largely a voluntary response.

A superficially similar reaction is common in severe spastic paralysis of organic origin, but there are important differences. In the organic case, as the pin is being drawn along the sole from the back to the front of the foot, jerky flexion movements associated with extension of the toes commonly occur before the limb becomes vigorously flexed. Sometimes, however, violent withdrawal is almost immediate. Observation of the after-response is then of value. In the organic case, if the spasticity is more extensor than flexor, the limb, after a brief delay, is vigorously thrust out with the muscles in strong contraction, the toes being usually extended. Should the spasticity be predominantly in the flexor muscles of the limb, the subsequent reaction to withdrawal is slower and jerky. Once these reactions have been seen they can again be easily recognized. Usually, however, the response to stimulation of the sole is not the only available physical sign for diagnosis. The tendon reflexes, the reaction of the muscles, if rigid, to passive stretching and to voluntary efforts, are all of the greatest value. The final conclusion will rest on the whole available evidence.

The other source of fallacy lies in the want of recognition of normal variations—for example, the confusion between the haziness of the optic disk in a hypermetropic eye and papilloedema, and between a large physiological cup and optic atrophy; so also is apparent weakness of one side of the face and tongue the result of natural asymmetry of the facial bones.

Physical Signs of Hysteria

A psychoneurosis is the outcome of an attempt to solve a mental conflict. The imperfect and irrational solution results in illness which, as in anxiety states, still leaves the patient with fears and obsessions. In hysteria, however the development of a physical disability, such as paralysis or blindness, is, as a rule, completely satisfy-

ing, and with its appearance worry vanishes. "Belle indifference" has long been known to be characteristic of the simple hysteric whose anxiety returns if he is compelled by the suggestions from a personality he believes to be stronger than his own, or by sudden emotional shock, to give up his fears and obsessions. The cure of hysteria, therefore, demands not only the disappearance by suggestion and explanation of physical disabilities, but also a reasonable adjustment, satisfying to the patient, of the conflict which led to their appearance. Hysterical symptoms may, however, and frequently do, form an incidental part of other psychoneurotic illnesses, and psychotic states, such as depression and schizophrenia, as well as gross physical illnesses, are often not free from them.

Hysterical manifestations are mental in origin, and are determined by the individual's idea of what constitutes paralysis, loss of sensibility, or a fit. They do not, therefore, conform to the rules of pathological physiology and anatomy. It is this discrepancy that enables the physician to differentiate between signs of hysterical and those of organic origin.

Hysterical Paralysis

Almost the whole body, or one side of it, or a limb, or only the peripheral part of it may be affected. Paralysis limited to the adductors of the vocal cords, resulting in aphonia, is common. The distribution and form of the paralysis is determined by suggestion frequently provided by a physical illness or accident, which in itself is often trivial. Thus laryngitis may lead to aphonia, or a slight wound to the hand to paralysis of this part. The factor which determines the perpetuation of disability in hysterical form is a state of anxiety with consequent unhappiness, or a fear of the future, after the physical illness is over, and it may be that the patient unconsciously welcomes disablement so that he need not continue with disagreeable tasks or can attract sympathy, while at the same time the necessities of life, flavoured with luxuries, can be provided for him by others.

Characteristics of Hysterical Paralysis

It is often selective. All voluntary movement in the affected part may appear to be impossible, but there are no reflex signs of organic significance or wasting, unless the paralysis has lasted for many months. The paralysis may, however, be incomplete. In such cases two forms of reaction may be observed. The first is that the patient is unable to use certain muscles for one voluntary movement, while he is able to employ the same muscles for all other voluntary movements for which they are required. The following examples are illustrative. The hysterical aphonic talks in a whisper but can usually cough to command, equally a voluntary act. So also the act of writing is difficult or impossible in writer's cramp, although the hand is as good as ever for all other movements. That the paralysis represents an idea of disability is again shown by the case of the sergeant who, after fighting successfully for three years, quite naturally became tired of it, but discipline and a sense of duty compelled him to struggle on in spite of his desire to escape. During a bombing attack he was slightly wounded on the forearm, and soon after became unable to grasp a bomb or a rifle with his right hand, but never lost the power to use it for other purposes. The paralysis, which incapacitated him from fighting but for nothing else, enabled him to get the rest he required with preservation of his self-esteem.

Again, in the form of hysterical paralysis known as *astasia-abasia*, the inability is confined to standing and walking, for in bed all voluntary movements of the lower limbs can usually be well carried out. The same incon-

sistency can be observed in cases of ataxia. Thus, although the patient staggers in walking and sways when standing, especially if asked to do so with closed eyes, so long as these actions are in his mind; he will, nevertheless, stand steadily if his attention is directed to the examination of his pupillary reactions.

The second form of reaction consists of the display of excessive effort, which is manifest not only in a general way by clenched teeth and hands and of violent muscular exertion of the non-affected portion of the body as if the patient were trying to show that he was doing his best, but also by strong contraction of the opposing muscles at the joint of the affected limb which he is asked to move. Either no movement results, or it is accomplished in jerks due to irregular relaxation of the muscles opposed to the prime movers. These two modes of behaviour are diagnostic of hysteria, and, if recognized, cannot lead to confusion in diagnosis.

Passive movement of a paralysed limb in hysteria may evoke no resistance, or resistance of a diagnostic kind may be encountered. It is then proportionate to the effort expended by the physician in the sense that the more he tries to move the joint so the resistance steadily increases. This reaction, which is due to muscular spasm brought about by the unconscious or, more truly, the partially conscious efforts of the patient to resist, can easily be differentiated from the two common varieties of organic muscular rigidity. These are due to pyramidal and extra-pyramidal motor lesions. When one attempts to bend the paralysed knee of a patient with spastic hemiplegia, the so-called clasp-knife rigidity is encountered. At first the movement is easy, then resistance is suddenly encountered, but if pressure is maintained it gives, although not completely, and the rest of the movement can be carried out fairly easily and with diminishing effort. In Parkinsonism the tonic reaction of the affected muscles is different. It is displayed throughout the whole movement at the joint, but is jerky, hence the term "cogwheel" rigidity. Its jerky character can, as a rule, in slight cases of Parkinsonism, be most easily detected at the wrist, but it should be remembered that the hand may have to be moved in flexion and extension several times before it appears.

The various contractures met with in hysteria are the result of muscular spasm, which increases when attempts are made to overcome the abnormal posture either by the patient or the physician. Furthermore, postures of the limbs always differ, at least in detail, from those of organic spastic states, and not uncommonly the hysterical contracture is limited to a hand or foot. That hysterical contracture is due to active spasm is well shown in cases in which there is apparent weakness of one half of the tongue. The tongue, say, is protruded to the right, but when withdrawn into the mouth it still deviates to the same side, whereas if the unilateral paralysis had been organic, retraction would inevitably cause deviation to the opposite side. So, also, hysterical diplopia with convergent squint is the result of voluntary or semi-voluntary contraction of the internal recti.

No manifestation of hysteria can be recognized so quickly as the manifold disorders of gait. One or both limbs may be affected. The patient may drag the paralysed limb along behind him with the foot firmly scraping along the floor, or will ostentatiously, in his jerky and irregular progress, clutch at objects in his way that would give him support. The observer who may be helping him to walk is soon aware that the patient is trying less to support himself than to sink to the ground, quite unlike the sincere efforts of the paraplegic whose disability is of organic origin. Hysterical helplessness in walking is all the more striking if, as may be the case, movements of the lower limbs are well carried out in bed.

Hysterical Sensory Disorders

Loss of sensibility in hysteria differs fundamentally from that due to organic causes. In the first place, it fails to conform to anatomical distributions—central, root, or peripheral. Thus, cutaneous analgesia in a limb tends to stop short at obvious landmarks such as the wrist, ankle, or knee. If it extends to the groin in front it is bounded behind by the fold of the buttock, and does not include the lower sacral areas. If the whole upper limb is analgesic the upper border encircles the shoulder-joint, a distribution which would be impossible in organic states. So also the front of the trunk may be insensitive while the back is intact. Secondly, the boundary of the analgesic area is sharply defined. Polyneuritis and subacute combined degeneration give rise to cutaneous sensory loss encircling the lower limbs or trunk, but the analgesic areas correspond to peripheral or segmental sensory distributions and their upper borders are never abrupt.

In organic states examples of sharp delimitation between regions of normal sensibility and sensory loss are few and are well explained on anatomical and physiological grounds. When, for example, there is analgesia over one half of the body, the line of demarcation between the areas of abnormal and normal sensibility is sharp. But should there, in addition, be absence of vibratory sense in the limbs and abdomen, on one side, a vibrating fork can still be appreciated by the chest, especially if it is placed near the sternum, since the chest is a sounding-box. In complete hysterical hemianaesthesia, however, appreciation of vibration may well be abolished on one half of the chest as well as cutaneous sensibility.

When there is complete loss of sensation below a level on one or both sides of the body, if the sensory loss is organic its upper border will have segmental or root characteristics, whereas in hysteria it will not. For example, the upper border of analgesia on the trunk, when organic, is never strictly transverse, but follows well-known wavy lines, whereas in hysteria it does not. Lastly, because of the budding out of the limbs, certain sensory root and segmental areas become contiguous with others from which they are separated by those which correspond to intervening roots or segments, so that the sensory overlap is absent. When this happens the borders of sensory loss are sharply defined. These regions of strict delimitation are especially between the outer and inner aspects of the upper arms, the anterior and posterior aspects of the thighs, and the sacral saddle-shaped areas in the buttocks; on the trunk, a similar abrupt transition is found roughly at the level of the second ribs in front and the spines of scapulae behind, where the dermatome of the fourth cervical segment marches with that of the second thoracic.

A third characteristic of hysterical sensory loss is that it can be varied and abolished by suggestion. A fourth is that the inevitable, indirect consequences of organic sensory loss may be absent in hysteria. For example, ataxia of the lower limbs in polyneuritis, tabes, or Friedrich's ataxia is due to loss of postural sensibility from lesions of peripheral nerves, sensory roots, or posterior columns, and is naturally worse in the dark and if the patient's eyes are covered. In carrying out Romberg's test in the hysteric, however, the response obtained will, as has already been mentioned, depend upon whether or not he understands that his steadiness or some other function is under investigation. Hysterical loss of vision illustrates the same principle. Blindness may appear to be complete; but, even so, the pupillary reactions to light are brisk, the fundi are clear, and the patient usually succeeds in avoiding objects when he attempts to walk about. Spiral fields of vision have long been known to indicate hysteria, and doubtless are the result of sugges-

tion in performance of the test. Unilateral blindness and deafness may occur in association with complete hemianaesthesia. The psychogenic origin of the deafness as in cases of bilateral deafness can be recognized by evoking nystagmus by rotation of the body, and the blinking reflex by a sudden noise.

Fits

It is sometimes difficult, if an attack has not been observed by a competent witness, to decide whether a fit is epileptic or hysterical, especially if there is no history of injury during a fall, incontinence, or tongue-biting. All these features, which are common in epilepsy, may at the same time be absent. If the physician or a trained nurse has observed an attack it is usually easy to arrive at a correct diagnosis. The hysterical seizure is characteristically a dramatic performance with arching of the limbs and trunk, violent purposive movements, and often shouting and articulate speech. The patient may become cyanosed from holding his breath, but his eyelids are usually tightly shut and resist efforts to open them, and his pupils react normally to light. Furthermore, after the attacks the tendon-jerks and the plantar responses are invariably normal. Difficulties may, however, arise if the physician is unacquainted with less recognized forms of epileptiform attacks. Thus, in so-called tonic fits due to sudden disturbance of function of the upper part of the brain stem from organic lesions such as tumour or tuberculous meningitis, there is opisthotonos and the limbs are rigid, the lower in extension with pointing of the feet and toes and the upper flexed or extended; but the eyes are open, the pupils are usually inactive to light, and incontinence may occur. Certain minor seizures, especially if unassociated with loss of consciousness, may present more difficulty. Thus in "myoclonus epilepsy" as the result of sudden muscular contraction the patient, although conscious, may fall down, or, if an upper limb is the part affected, an object held in the hand may be thrown across the room. So also in cases of "inhibition epilepsy," in which muscles of the limb are suddenly relaxed, falling may occur without apparent loss of consciousness. Again, involuntary clonic movements are often limited to a limb or one side of the face in Jacksonian attacks associated with focal cerebral lesions, but physical signs are to be found in the affected part at least for a time after the seizure. The necessity for routine examination of the optic disks is recognized but is not always applied.

Hysterical amnesias and fugues may occasionally be difficult to differentiate from automatism following petit mal attacks, but a careful history is usually decisive. Moreover, the hysteric in a fugue is not inclined to empty his bladder, as in the classical case of Trousseau's Judge, remove his clothes in public, or be homicidal; in fact, his actions usually pass unnoticed. A chronic epileptic is often an emotional subject, and may show hysterical symptoms from time to time like other unstable persons. Nevertheless, there is little justification for the term "hystero-epilepsy."

This leads to the last point to which I would draw your attention. Emotionalism does not necessarily mean that the ill person has not some organic illness. It is perhaps equally unnecessary to say that states of anxiety may act as precipitating causes of physical disturbances, such as migraine, intracranial hypertension headaches, and occasionally epileptic attacks, as well as aggravating enfeeblement of organic origin. But it is less generally recognized that emotionalism may in turn be due to proven structural disease of the brain. Emotional facility, with an undue tendency to laugh or cry, is one of the commonest manifestations of disseminated sclerosis, a disease in which the transient character of the early disorders of function is apt to lead the unwary into making a wrong diagnosis.

All the more so if at the time of examination no physical signs are discovered. A similar emotionalism occurs also in pseudo-bulbar palsy, progressive bulbar palsy, chronic alcoholism, dementia paralytica, and occasionally with cerebral tumours, but by the time it appears, clear indications of structural damage can usually be found.

Lastly, the apathy of Parkinsonism, which is often more apparent than real, may be wrongly interpreted as psychogenic. But quite apart from the unmistakable physical abnormalities, even in early cases, which are now common knowledge, the lack of emotional reaction should in itself lead one to suspect its organic basis.

In conclusion, while the analysis of symptoms and signs is of the utmost value in the subject under discussion, the investigation of the behaviour of the individual as a whole in the past as well as in the present is the basis upon which diagnosis has often to rest. Let us not forget, too, that a neurotic may develop organic troubles like other people, and also that a person may become mentally unstable as the result of anxieties consequent upon physical disabilities. In this respect, minor head injuries ought especially to be remembered.

DIFFERENTIAL DIAGNOSIS OF ORGANIC AND FUNCTIONAL NERVOUS DISORDERS*

BY

A. A. W. PETRIE, M.D., F.R.C.P.

PHYSICIAN FOR MENTAL DISEASES, CHARING CROSS HOSPITAL

The differential diagnosis between functional and organic nervous disease is obviously a wide subject. At the outset an exact definition is needed as to what constitutes functional nervous disease. Broadly, this may include all nervous manifestations in which no evidence of pathological changes in the nervous system has been demonstrated. Cases of dysfunction without demonstrable organic lesion may therefore be classed among the functional cases, and disturbances resulting from psychological stresses in the highest psychic level will also need to be included. The symptoms of the diseases commonly known as the neuroses or psychoneuroses will, of course, come under review, as will some of the psychoses. While some psychoses, such as general paralysis, have a very evident organic basis, others represent derangement of function, and little objective organic evidence may be obtainable.

The association of so-called functional elements with organic lesions raises an even wider issue. Cases in which no functional element was apparent before an organic lesion developed bring up the whole question as to the relation between these groups, and as to how far they can be justifiably separated. The attempt may be difficult, as may be judged from the fact that a leading neurologist stated, in discussing hysteria, that there were few organic symptoms which he had not seen reproduced in that disease. Functional disorder of the nervous system may disturb any bodily system and lead to confusion with diseases other than those of the nervous system, and separating the functional incapacity in a given lesion from that due to organic disease may be very difficult. In a short paper it is obviously impossible to deal with all aspects, but I shall endeavour to show the importance of examining the problem as a whole, and of not neglecting the psychological approach.

* Read in opening a discussion in the Section of Neurology, Psychological Medicine, and Mental Diseases at the Annual Meeting of the British Medical Association, Bournemouth, 1934.

Consideration of the person's whole make-up and circumstances often renders the diagnosis clear when individual symptoms may be very puzzling. Recognition of a hypochondriacal attitude of mind is of great importance in the valuation of symptoms. This abnormal concentration on the individual's own body represents a psychological abnormality, whether it is present as a simple neurosis or whether associated with a depressive or paranoid psychosis.

Neurasthenia

As I am approaching the subject rather from the functional point of view, I shall first consider the different aspects of the neuroses. While hysteria and its subsidiary, the traumatic neurosis, perhaps provide the principal problem, neurasthenia and anxiety neurosis, and the various mixed types, also need consideration. By neurasthenia I mean the exhaustion neurosis, in which the patient shows marked mental and physical fatigability.

The individual is usually a limp, sparsely nourished, unhealthy-looking person, unable to concentrate, finding all exertion, mental or physical, too great. If attempting to perform a physical act he rapidly tires, and he becomes increasingly inefficient when faced with a mental task. Special tests prove this to be a feature of a genuine case. Such a state of affairs exists to some extent after any great and debilitating illness, but the conditions persist in the neurasthenic long after the recuperation would have taken place in the normal individual.

The presence of anaemia, tuberculosis, or any chronic associated factor must of course be eliminated, and then arises the question of some chronic toxæmia. The teeth and intestines fall under suspicion, sometimes rightly, but at times drastic measures in regard to these are adopted without avail. Sometimes the case is one of incipient melancholia, the loss of interest and disinclination to exertion being a stage in the depressive phase of a cyclothymic or manic-depressive psychosis. What is at first regarded as a post-influenzal debility, and then as neurasthenia, may ultimately prove to be the early stage of a depressive psychosis. Usually, however, the associated depression, as opposed to a limp apathy, differentiates between them. Too much listless apathy and indifference to external circumstances would, on the other hand, arouse the fear that the case was really one of schizophrenia, but the pure neurasthenic is not given to fantasy, "day dreaming," and other features of the *præcox* case. Although the fatigability of the muscles in myasthenia gravis to some extent suggests neurasthenia, it is not common to confuse the condition. The facial muscles are usually quite mobile in neurasthenia, and there is no paralysis of groups of muscles such as the orbicularis palpebrarum or palatal muscles. The acute symptoms of encephalitis lethargica are hardly likely to be confused with neurasthenia. The dulling and immobility of mind of the encephalitic might be confused with a neurasthenic or depressive individual, but the mask-like rigidity and salivation so common in the former are quite uncharacteristic of the latter. The dull immobility of the *præcox* syndrome, possibly associated with salivation, is far more likely to be confused with the effects of the encephalitis lethargica, and confusion has at times arisen. The encephalitic, however inhibited, is more fully alert, given time to express himself, while the *præcox* is actually confused, and no amount of time allowed for expression will improve matters. The mannerisms and wrinkled forehead of the *præcox* are usually distinctly different from the mask-like face of the encephalitic. Mentally, variability and in consequence, or perhaps stupor, will contrast with the slow, inhibited endeavour to find expression. This slow,

hesitant expression may perhaps resemble the retarded melancholic, whose furrowed facies contrasts with the encephalitic. Genuine acute depression is sometimes added to the encephalitic syndrome. A full recognition of the mental and physical wreckage that the disease has brought may cause the individual to feel that death is the only solution to his difficulty. Suicide is a real risk in such cases, which are sometimes very logical in their depression.

The older type of neurasthenic presents other problems. Such cases are not obviously of the type of which it has been said that their vitality has been squandered by their ancestors. In other words, the predisposing congenital element is less evident, and one seeks other causes. Real mental and physical strain may have preceded a collapse, and the toxins of alcohol, tobacco, etc., may have influenced them. When the stress reaches breaking-point quite a sudden collapse may occur in these cases. Eliminating the more obvious alcoholic syndromes, neurosyphilis should be remembered as a possible cause. A neurasthenic attack in the middle-aged should always be regarded with suspicion, particularly if the patient has not previously shown tendencies of this type, and signs of neurosyphilis should be looked for and the serological findings tested if there is doubt.

Anxiety States

The varied manifestations of the anxiety states perhaps provide more difficulties than other syndromes owing to the variety of the symptomatology, and also owing to the fact that the patient is obviously so sane and so genuinely affected by his symptoms. Fear and apprehension is the prevailing feeling of the individual, who is in a general state of excitation. Many symptoms suggest sympathetic stimulation. Some symptoms, however, suggest disturbance of the parasympathetic supplied through the vagus, and while the names vagotonia and sympathicotonia have been applied to the different conditions, the symptoms are so frequently mixed in type that it is better merely to say that they represent functional disturbances of the autonomic nervous system.

Closely allied are the vasovagal attacks, in which the patient exhibits a sudden sense of oppression, usually starting with an epigastric sensation, followed by dyspnoea, and disordered action of the heart and even a sense of impending death. Similar symptoms are observed in the acute or paroxysmal phase of the anxiety syndrome, and when, as rarely happens, consciousness is lost, the condition may even suggest epilepsy. It is, however, much more likely to suggest some other cause for fainting, and may even be mistaken for some cardiac condition such as coronary thrombosis. The patient usually merely fears he is about to lose consciousness; he is in a state of acute fear and apprehension, and may fall over slowly, clutching at things as he falls, and making every effort to regain control. There is not the careful disposition and dramatic effect seen in the true hysterical fit, the patient being genuinely distressed.

At times the condition may suggest a minor cerebral attack, as the patient may complain of a feeling of congestion in the head or say he feels as if his head were going to burst. The pulse is rapid, and may even seem inhibited, but irregularity apart from cardiac disease is, in my experience, not usual. Respiratory attacks, with a breathlessness resembling air-hunger, may also be a feature of the acute attack. A study of the interparoxysmal symptoms and of the psychological basis will help to make diagnosis clear. Where there is obvious sexual excitation without relief, faulty methods of contraception, leading perhaps both husband and wife to seek advice, or general causes likely to lead to anxiety, the

nature of the case becomes clearer. The interparoxysmal symptoms, although more likely to resemble diseases of other systems, will help in elucidation. The disordered action of the heart with precordial pain, and no evident organic lesion, so commonly seen during the war, is a common symptom. Sweatings of the palms may occur, and this may be more generalized. The tremor, combined with the rapid cardiac action, may suggest exophthalmic goitre, with which the condition may, indeed, be associated. Symptoms of intestinal disorder have been referred to, such as eructation, vomiting, various results due to irregular peristaltic contractions, and diarrhoea, even with tenesmus—all symptoms of the fear syndrome, and aptly illustrating the well-known phrase, "Their bowels were turned to water."

In some cases the psychological basis may be less evident, and abnormal vagal stimulation on the lines of oculo- and gastro-cardiac reflexes appears to result from gastro-intestinal movements. At times abdominal manipulation will make the patient realize that the origin of the vague discomforts and sensations complained of lies in movements of the gut. Between the anxiety syndrome and the hysteric occurs anxiety hysteria, a definite neurosis, in which are classed those whose hysterical reaction mainly expresses itself in mental anxiety symptoms. Apart from this, mixed types occur in which it may be difficult clearly to separate the anxiety and hysterical symptoms.

Hysteria

The hysteric is the classical simulator of many diseases, but much time and trouble might be saved if more effort were made to study the patient as a whole, instead of concentrating upon individual symptoms. To deal with a hysteric much study of the patient's immediate and remote situation is necessary, but an accurate appreciation of the immediate situation will often enable a quicker and more accurate diagnosis to be made than if the approach had only been from the physical aspect.

Some hysterics are first seen in the psychological department of a general hospital, while others arrive there with a dossier from all the other departments, elusive symptoms having been followed from system to system. The family doctor is in a particularly favourable position to see and appreciate the family situation, which is the basis of the faulty reaction. At times, by judicious advice, he may alleviate the intolerable situation which is being shirked. Hysterical symptoms represent an idea of the patient tending to satisfy the subconscious purpose. The nature of the symptoms may be determined by the type of disability most useful to obtain that end, or in case of a traumatic neurosis by an original injury to that part. The lesion is usually a loss of function, but is associated with the general petulant emotional reaction of a hysteric. Such lesions may occur either on the psychological or on the physical plane. Among the former may be mentioned the amnesias, fugues, cases of double personality, and also the stupor, while the latter will show sensory and motor changes—that is, anaesthesia, hyperaesthesias, and, on the motor side, convulsions and palsies.

Dealing first with convulsions, a case of major epilepsy seen in a fit is probably the simplest problem. The hysteric seldom produces the different stages of the fit at all realistically, and still less the post-epileptic confusion and coma. A well-described true aura is also against a diagnosis of hysteria. In the post-epileptic state extensor plantar responses would negative hysteria but not epilepsy. To some extent the general mental make-up will help to differentiate the childish and probably dull and irritable epileptic from the petulant but quicker-witted hysteric. In some cases this will not help

particularly in the very difficult problem of the hysterical epileptic—that is, the epileptic with hysterical manifestations. Where obvious attacks of true major epilepsy alternate with equally obvious hysterical outbursts, little difficulty arises, although an observer who has only seen one or other group may be deceived. Rarely, epileptics can simulate genuine fits to an extent which can deceive, and I have known a hysterical epileptic have realistic "pseudo-fits" at a demonstration. It is usually, however, the combination of petit mal with hysterical manifestations which deceives, and until some indication of the epilepsy, such as unexplained bed-wetting, occurs, the real nature of the case may be missed, always remembering that even these symptoms have been counterfeited by hysterics. The many other causes of convulsions are more likely to be confused with epilepsy than with hysteria, but an unexpected fit without previous history may arouse suspicion as to a functional origin.

Some Causes of Convulsions

Among the other causes of convulsions may be mentioned conditions causing intracranial tension. Fast-growing tumours are unlikely to be confused, as the evident signs of pressure develop, but slow-growing tumours in which signs of pressure develop slowly may cause confusion. In a case in point of one of these slow-growing tumours, an oligodendroglioma produced the first fit, for which the patient was invalided from the Navy seventeen years before death.

Localization by mental symptoms is not reliable owing to the variability of these symptoms, which may occur even in subtentorial cases. Tumours of the frontal lobe, and perhaps of the corpus callosum, are, however, more apt to be associated with early mental symptoms than those in other areas, and deterioration and dementia may occur even before signs of pressure make the nature of the case obvious. At times such a dementia may be associated with dysarthria, causing general paralysis to be suspected in what is really a frontal tumour syndrome. Confusion and deterioration occur in cases of Pick's and Alzheimer's diseases, as well as in cases of cerebro-arteriosclerosis, where temporary confusion from a recent vascular lesion may be added to a permanent deterioration. In all the above cases convulsions may occur which need differentiating from epileptic or hysterical manifestations, and similar convulsions may occur with alcoholism, and certain cerebral poisons such as lead, mercury, etc. The convulsions due to metabolic disturbances must be remembered, such as uraemia, eclampsia, and hypoglycaemia, and, in childhood, disturbances associated with infection, rickets, and teething, which last may represent the earliest signs of epilepsy.

A further convulsion which may need differentiating from epilepsy or hysterical convulsions is the fit associated with tetany. In one case, a woman of about 30 years, who had had a partial thyroidectomy for exophthalmic goitre, developed fits of a tetany type, some of which developed into generalized convulsions. Her blood calcium was low, but improved to normal under treatment with calcium and parathyroid. Her fits became less and less suggestive of tetany, and more characteristic of genuine epilepsy.

Convulsions can also occur in disseminated sclerosis, but it is not in this way that the disease is usually confused with hysteria. It is in the early stages that the variable losses of power with remittent tendencies occur, which cause the diagnosis to be at times in doubt before evident signs of the organic lesion develop. The reaction of the disseminated case is at times not unlike that of the hysterical, and hysterical symptoms may even be added to those due to the organic disease. Generally, the paraplegia is more suddenly and dramatically complete in

a hysteric, whereas other organic symptoms will be evident in the disseminated case, presenting a complete spastic paraplegia.

Motor and Sensory Disturbances in the Hysteric

Hysterical paralysis may affect any of the senses or limbs, or a combination of limbs. The lesions most commonly met with are probably paraplegia or monoplegia of an upper limb, and aphonia. The hysterical paraplegia leads to a complete incapacity, necessitating the care and eliciting the attention and pity that the hysteric desires. In the poorer classes it may lead to admission to a hospital, and so cause a removal from irksome home conditions. Signs of organic lesion will, of course, be absent, although disuse phenomena may occur later. Control of organic sphincters will usually be retained, although at times lack of control of these functions may occur which may be accompanied by neglect of person. Usually, however, apart from the lesion complained of, conduct will be excellent, and the individual will suffer as little inconvenience as possible, consistent with the lesion. Sensory loss may or may not accompany the paralysis, and when present may help with the diagnosis, owing to inconsistencies incompatible with an organic lesion. The underlying psychological idea of a paralysis may at times be traced, as in the case of a girl with a monoplegia of an upper limb which she had used to repulse her lover when he attempted liberties, the paralysis representing subconscious regret that she had so repulsed him. Usually the diagnosis is not difficult, the paralysis being limited to a movement or limb. When a movement is taking place, apparently with great difficulty, marked contraction of the antagonistic group of muscles will be evident, as well as contraction of the primary movers, which would not occur in a genuine paralysis. If rigidity is present investigation increases it, and endeavouring to overcome it provokes emotion from the patient. In gait, the tendency of a hysteric is to call attention to his lesion by dragging the limb, whereas the paralytic endeavours to compensate for his deficiency by circumduction. Similarly, tremors increase on observation and cease when attention is distracted to other parts.

The movements known as tics are commonly attributed to automatic or habit spasms, possibly associated with a local irritation or stimulus. At times, and in their early stages, they represent definite symbolic movements on the lines of a compulsion neurosis, the performance of which satisfies the unconscious wish whose emotional effect has been transferred to the symbolic act. The treatment of such cases is difficult, but tracing the tic to its origin, where this is possible, should release the pent-up affect attaching to such symbolic movements. Sensory loss without paralysis is much less usual in hysterical patients, although hyperaesthesia may be complained of as a means of eliciting sympathy. The hallucinatory disturbances of cutaneous and organic sensations seen in some of the psychoses are complained of in more general terms as burning or electrical sensations, and not as painful points or definite specified hyperaesthetic areas. Further, the depressed cyclothymic patient has a very different general reaction, and, although in certain phases the schizophrenic may resemble the hysteric, his reaction is essentially introverted, and he is unlikely to obtrude his symptoms.

Hyperaesthesia and other disturbances associated with dyspareunia due to some sexual incompatibility are important, as the whole group of symptoms is readily understood when the underlying attitude is revealed. Such symptoms mainly cause confusion with minor gynaecological conditions, and range from simple complaints of pain to elaborate hypochondriacal ideas with abnormal

paranoid trends. They include real cases of abnormal sexual incompatibility, ranging down to cases which have failed to adjust in regard to contraception, with fears of pregnancy, and menopausal cases, where one of the parties has ceased to desire sexual relations. An appreciation of this saves much investigation of elusive symptoms.

Coming to the special senses, blindness, deafness, and loss of speech may all occur. Elaborate tests to deceive the senses have been evolved to prove the functional nature of the cases. Unilateral blindness is perhaps more usual; conjunctivitis is not uncommon, being easy to produce and resulting in a similar incapacity. Aphonia, where phonation is lost but articulation is preserved, is the common hysterical lesion, as the patient can still converse in a whisper, again suffering incapacity without great inconvenience. The partially adducted state of the vocal cords is characteristic. The adoption of face-saving methods in inducing speech by faradism facilitates cure of this symptom.

Mutism is more generally a sign of stupor, although it may occur in persons fully alert mentally, but silent owing to hysterical or delusional ideas. Among the common causes of stupor may be mentioned post-epileptic phenomena, depressed cyclothymic cases, hysterics and schizophrenics, and cases of so-called idiopathic stupor. Somnolent cases of encephalitis lethargica may resemble this state, and cases of pathological somnolence or narcolepsy, some of which may be associated with organic lesions, such as cerebral tumour. Among the rarer conditions may be mentioned such a phenomenon as cataplexy, a condition in which movement is impossible, although consciousness is retained. While some of such cases have a physiological basis, many on investigation will be found to be cases of hysteria.

Without an adequate history, differentiation between the conditions may be difficult. The principal difficulty is in separating the cases of hysteria from the praecox syndrome. The hysterical type, fully alert to her surroundings, who, under suggestion or other suitable conditions, passes into a hysterical trance, is usually obvious, but when extended periods of stupor, with few if any remissions, occur, with marked dissociation, the fear will be that the case is one of serious schizophrenic dissociation, even when mannerisms and other suggestive schizophrenic symptoms are absent.

In conclusion, I would again repeat that neglect of the psychological aspect leads to failures in diagnosis and treatment, owing to undue emphasis being placed on the individual symptoms. When both physical and mental aspects are considered, a true perspective is obtained, with beneficial results both to doctor and to patient.

With the July issue of the *Fortschritte auf dem Gebiete der Röntgenstrahlen* began the fiftieth volume of a monthly periodical which has rendered very great services to radiology the world over. Founded in 1897 by Heinrich Albers-Schönberg, who was himself a radiological pioneer, it has given publicity to many of the outstanding discoveries in connexion with x rays, and been a foster father to various of the subsequent journals which dealt with the more specific applications of this subject as they came into being. It has been adopted as the official organ of radiological societies in Czechoslovakia, Austria, Hungary, and Russia, as well as in Germany, and has won universal recognition as a sound and reliable as well as a progressive periodical. It is only right that the July issue should begin with the first Albers-Schönberg memorial lecture, which was delivered at the congress of the German Radiological Society in Baden-Baden last April. The present editor is Professor Rudolf Grashey-Köln.
